A Seven-Day Journal

The Prevention of Fires Aboard Ship.

At a meeting of the Society of Consulting Engineers and Surveyors, held on Wednesday, October 18th, in the Library of Lloyd's under the chairmanship of Sir Percy Mackinnon, Mr. Arthur T. Woods, director of Royal Mail Lines, Ltd., read a paper in which he gave a number of practical suggestions for the prevention and control of possible fires at sea. While paying tribute to the adequacy of the present Board of Trade regulations, Mr. Woods strongly advocated the patrol system and the organisation of trained fire-fighting units, alike for voyage and port service. Referring to alleyways and corridors, Mr. Woods suggested further isolation measures by the introduction of fire-resisting doors at suitable points, along with fire-resisting baffles. These, he suggested, might be constructed of metal, and in all cases fire-resisting paint should be employed. Such measures, he said, would break up the air flow and retard the spread of fire. He advocated the further decentralisation and individual control of forced ventilation circuits, and the use of steam, where possible, for fire extinguishing purposes. Sprinklers, he suggested, should be connected with the electric bell system in the cabins so that when they operated an alarm was at once given. Reference was also made to the "emulsion" system of putting out oil fuel fires, and in general the desirability of a more extended use of impregnated timber and reliable non-inflammable paint for constructional woodwork and decorative fittings.

The West Middlesex Sewerage Scheme.

Some account of the scheme for co-ordinating the sewerage of West Middlesex, a civil engineering work of major importance, was given by Mr. J. D. Watson at the meeting of the Royal Sanitary Institute, which was held in Buckingham Palace-road on October 17th, under the presidency of Dr. George F. Buchan. Our readers will probably remember the outline of this scheme which we gave in The Engineer of March 17th, 1933. It involves the expenditure of some six millions sterling and the preliminary work has been completed. In his paper Mr. Watson told the story of the scheme, and how, when it was found that the increase in the population of the district—an area of some 160 square miles—had developed beyond all previous ideas, it became obvious that the natural drainage of the district could not cope with the increasing discharge of sewage effluent without the native streams becoming objectionable. The alternative of collecting the sewerage and the storm water from all the score of districts concerned, and treating the mixture at a central plant, was considered at great length, and ultimately it was decided by the Middlesex County Council that a plant should be put down at Mogden and connected with the existing drainage system by a network of intercepting sewers ranging in diameter up to 12ft. 9in. and having a total length of 67 miles. These sewers, it is estimated, will ultimately discharge at the works 480 million gallons a day. This flow, some of which will have to be pumped up from low-level sewers, will be treated by the activated sludge process at Mogden and the clear water discharged into the Thames at Isleworth through two conduits, each 11ft. in diameter. The resultant sludge will be pumped up a rising main, about 7 miles long, to be digested at Perry Oaks and turned, if possible, to a useful purpose. A feature of the Perry Oaks site will be its complete isolation from the surrounding country, by means of a puddle wall carried down to the London clay, and a drainage system connected with the local sewer, so that there may be no possible contamination of the adjacent streams.

Electrical Development.

In his presidential address delivered before the Association of Supervising Electrical Engineers on Wednesday, October 18th, Mr. J. M. Kennedy said that returns showed that last month the production of electricity was 10·8 per cent. greater than in September, 1932. Over the first nine months of this year there was an advance of 8·2 per cent. compared with the corresponding period of 1932. Whereas ten years ago the coal used in producing electricity was only 50 per cent. of that used in gasworks, the amount consumed in the two cases was now practically equal. Referring to railway electrification, Mr. Kennedy said that, comparatively speaking, it was a much more productive line of capital development than that of constructing new roads. Electrification provided traffic managers with means of attracting traffic, for it gave greater speed, cleanliness, and general comfort. The economy of shorter trains at more frequent intervals and the general absence of smoke and smell and better timekeeping were other important advantages. Experience on the Southern Railway showed that a very great increase in traffic could result from electrification, and although anything like the same increase could not be expected on main lines, a regular half-hourly service of electric trains between such cities as London and Birmingham and Manchester would bring about a considerable increase in passenger traffic. Having regard to the national advantages of electrical development, engineers should aim at something in the nature of a five years' plan to electrify all towns and villages down to a minimum of 100 inhabitants and at connecting up at least 1,000,000 consumers a year, of whom at least 50 per cent. should be cooking electrically.

A Coal Burning Appliance Makers' Association.

At a meeting of representatives of engineering and industrial firms, held in London on Friday last, October 20th, a Coal Burning Appliance Makers' Association was formally constituted. Mr. Teeling Smith was elected the first Chairman, and a committee of eighteen members, representing the makers of industrial, marine, and domestic coal-burning appliances, was appointed. Mr. W. A. Lee, the Secretary of the Mining Association, said that the coal mining industry regarded the appliance makers as the spearhead of their effort to stimulate the consumption of solid fuel, and he welcomed the new Association because its co-operation was indispensable to the advancement of Britain's staple fuel. The new Association has been brought into being as a result of the initiative shown by the Coal Utilisation Council, which has realised from the first that the finest fuel would not give the best satisfaction or value if it was used with old-fashioned or indifferent appliances. The work of the new Association will include the standardisation of the terminology of coal-burning appliances and the establishment of agreed methods of stating comparative results and efficiency. It will co-operate with the Coal Utilisation Council in promoting the better marketing and distribution of definitely graded coal, and supplying useful information regarding developments in the utilisation of coal.

Shipbuilding and the North-East Coast.

In his presidential address delivered at the annual general meeting of the North-East Coast Institution of Engineers and Shipbuilders at Newcastle-on-Tyne, on Friday evening, October 20th, Mr. R. J. Walker stated that he felt at the moment that it was safe to make the observation that there were signs of a general improvement in trade. The shipping industry was the first to be affected by any depression, and the last to benefit by any improvement, but recent official figures showed that the amount of laid-up shipping was less than what it was a year ago by some million and a quarter tons, while there were half a million more tons of shipping in commission to-day than a year ago. These facts seemed to indicate that we were now approaching brighter conditions. A revival in trade would, Mr. Walker continued, be a means of putting to the test the activities and initiative of our industries. Never in the history of the British shipbuilder and engineer had there been, he said, a time of greater necessity for putting forth in our work our very best endeavours in order to maintain our national reputation as the finest shipbuilders in the world, a reputation which had in no small degree been subscribed to by the work performed on the North-East Coast. That area, Mr. Walker continued, would, he was certain, as in the past, continue to play an important part in the production of tonnage which would help to win back the shipping prosperity of our country.

Iron and Steel Developments at Cardiff.

In a letter addressed by Sir John Beale, the chairman of British (Guest, Keen, Baldwins) Iron and Steel Company, Ltd., to the Lord Mayor of Cardiff, last week, an extensive development scheme in connection with the works of the company at Cardiff was outlined. The new works will provide for the manufacture of about 300,000 tons a year of billets and sheet bars in the first instance, with provision for an increased output if the demand should warrant it. They will, it is expected, take about two years to build and equip, and will give direct and permanent employment to about 1500 men. By utilising a proportion of the existing plant molten iron from the blast-furnaces will be used in the manufacture of steel and the great natural advantages of the site further developed. It has been shown possible to produce at the proposed new works both billets and bars at a cost which should bear favourable comparison with other steel works and enable the output to be sold at a price satisfactory to users, which would, at the same time, give a reasonable return on the large capital outlay. The board has given instructions for the remodelling of a second blast-furnace and for a start to be made in clearing the site. The Lord Mayor of Cardiff has arranged for a deputation of the City Council to meet the company's directors at an early date.

Distribution.

In a Journal note of February 10th we dealt with the proposal to establish a British Distribution Committee in connection with the British National Committee of the International Chamber of Commerce. A step towards the establishment of this Committee has now been taken by the British National Committee, in collaboration with eight of the leading manufacturing firms, which have pledged themselves to contribute towards this work a minimum of £100 per year for three years or £50 for seven years. An appeal is now made for further support of a movement which is intended not to replace, but to supplement and extend, efforts now being made in specialised corners of the distributive field. The suggestion is made that the root cause of the present depression is the world's failure to distribute adequately the commodities which scientific method and modern technique can produce in superabundance. Costs of production, it is pointed out, have been steadily lowered for more than thirty years, whereas, on the other hand, costs of distribution have been rising, owing in a large measure to ignorance of the basic facts of the distributive process. The circumstances, it is held, demand urgently the formation of a British Distributive Committee, and all inquiries relating to the proposed Committee should be addressed to the Secretary of the British National Committee of the International Chamber of Commerce at 14, Queen Anne's-gate, London, S.W.1.

Forty-Hour Week Negotiations.

On Friday, October 20th, the joint committee of the trade unions of the engineering and shipbuilding industries met in London to hear replies from the employers' federations with regard to the unions' application for a forty-hour working week, without reduction in pay. The Shipbuilding Employers' Federation only sent a formal acknowledgment of the unions' application, but the Engineering and Allied Employers' National Federation wrote asking for further information with regard to the questions, first, as to how the proposed reduction of hours would reduce the present unemployment, or would create additional employment, and, secondly, how would the extra cost thereby involved, and the additional cost which would be incurred by increasing the hourly rate, be absorbed by the industry. It was decided not to answer these questions, but to write again to the Engineering Employers' Federation expressing the surprise of the unions at the new departure of opening correspondence on an important application when a request for a conference had been made. It was decided to remind the employers that in April last they stated that when the investigations then being made were completed, they would invite the unions to a conference to examine the problem of the industry's depression and consider what constructive steps might be taken for the betterment of the situation.

Accident to a Mail Plane.

It is now some years since the Air Ministry invited the aircraft manufacturers of this country to submit designs for a high-speed long-distance mail-carrying aeroplane. The general requirements laid down by the Ministry were that the machine should be capable of carrying 1000 lb. of mail and of flying non-stop for a distance of 1000 miles at a speed of 100 miles an hour. Several designs were submitted. In our issue of January 8th, 1932, we described and illustrated the type evolved by Saunders-Roe, Ltd. Another design produced by Spartan Aircraft, Ltd., was referred to in the same issue; while a third, the Boulton and Paul mail carrier, was illustrated in our issue of January 6th, 1933. We regret to learn that on Saturday, October 21st, the Boulton and Paul machine was completely wrecked while undergoing supplementary trials at Martlesham Heath. The machine had already been tested with satisfactory results by Flight Lieutenant Boothman, and on Saturday was being flown by Flight Lieutenant Richmond for the purpose of a further test, when, for some reason not at present disclosed, it crashed from a height of 1200ft. The machine was completely wrecked, and the pilot severely injured. It is understood that it had shown itself to be capable of carrying 1000 lb. of load for a distance of 1250 miles non-stop at a speed of 172 miles an hour, and to have a top speed of 195 miles an hour. It was fitted with two Bristol "Pegasus" engines of 575 horsepower each. It was of the biplane type, and not a monoplane, like the two other designs mentioned above.

A French Railway Disaster.

It is with regret that we have to record a serious French railway accident, which took place at 11.35 on Tuesday morning, when the Cherbourg–Paris express was passing over a viaduct between the stations of Conches and La Bonneville, near Evreux. The train, which it is estimated was travelling at a speed of about 65 miles per hour, was derailed, and the engine and tender with the guard's van and four carriages were precipitated over the viaduct into the river, which runs in a ravine some 30ft. below. Some thirty persons were killed and thirty-two injured. The first three coaches, which were of wood, were completely telescoped, and it was in them that the greatest loss of life took place. The last four coaches of the train remained intact. A preliminary inquiry was opened on the spot by the railway officials, and it is stated that no suspicion of foul play, which was rumoured in some quarters, could be found. It is thought, however, that as a gang of platelayers was shifting ballast near the scene of the accident, it may be probable that the rails were displaced as the train took the curve. No reason, however, can be given as to the cause of the accident until results of the official inquiry have been made known.

New Methods of Excavating Quicksands.*

By Sir HENRY JAPP, K.B.E., M. Inst. C.E., M. Soc. C.E. (France).

No. I.

Introduction.

In carrying out civil engineering works involving excavations for deep foundations, shafts or tunnels, engineers in all countries are confronted from time to time with what is commonly known amongst workmen as "bad ground." As the geological conditions are different in every continent, engineers have developed their individual methods, which vary in the distinctive national systems of timbering for trenches and tunnels.

The most difficult type of "bad ground" to be excavated generally consists of a fine wind-blown sand under water pressure called quicksand. Means more or less successful have been developed for dealing with such material, by relieving the pressure or holding back the water in such a way that the excavation can proceed without the quicksand boiling up and causing "blows," resulting in settlement and disturbance to the surrounding ground.

In excavating large areas for dock construction it is usual in water-bearing districts to sink sumps below the bottom of the work at strategic points, so that the water may be pumped and withdrawn from the subsoil. If the area is composed of open sand and gravel the volume of water is likely to be large, but there is no great difficulty in draining it providing sufficient pumping appliances are supplied. If, however, the material to be excavated is of a fine close sand, the water does not percolate freely to the sumps, and consequently many more sumps are required. The effect of pumping at a depth below the ground surface is to depress the water level near the sump. After pumping for some time it will be found that the level of the water in the ground rises from the bottom of the sump in the form of an inverted parabolic cone. In open sands the curve is flat, while in close sands the water curve rises steeply from the sumps, and unless the sumps are comparatively close together the inverted cones rising from adjacent sumps intersect above the bottom of the excavation, thus leaving the ground still under water pressure, resulting in the sand above the bottom of the excavation being unstable, and consequently "blows" occur.

In trenching nowadays it is usual to attempt to cut off the water by driving steel sheeting. In sinking deep shafts the freezing process has been successful in getting through beds of quicksand to the solid rock below. If the water head in the quicksand bed does not greatly exceed 100ft. it is possible to apply compressed air, so that the excavation of the shaft can proceed in the dry with entire safety. In tunnel driving compressed air is the most satisfactory method for overcoming difficulties in quicksand, the freezing process having proved quite unsatisfactory for this purpose.

In one case where a sump for draining a dock area had to be bottomed up through quicksand, in the writer's experience it was found, as the pumping and excavation proceeded, that the ground surface along with the timbering of the sump continued to sink. When it was seen to be impossible to sink the sump through the quicksand in the ordinary way, the pumping was stopped and the water allowed to rise; the last 8ft. of the sump was then sunk through the quicksand by divers. When the required depth was reached the divers formed a filter bottom to prevent the quicksand from coming in with the water, and the dock area was successfully drained without further settlement. In another case the same result was attained by means of compressed air for sinking the sump.

In cases where there is an underlying bed of dense water-bearing sands below the point of excavation under high water pressure the sinking of occasional sumps is not sufficient safeguard to prevent "blows," and this particular feature has always been a source of difficulty and danger. Until recently this situation has been met by the expensive process of sinking concrete monoliths by open dredging.

Recently there have been introduced to this country a new method which is proving of great benefit to civil engineering for dock excavations in cases of this kind.

This is the water-lowering process, by means of frequent wells of small diameter which reduce the water level.

Water-Lowering Process.

The method of draining open sandy soil by means of sumps is an old-established system, but the draining of fine close sandy soils under a head of water is impracticable by this method. The water-lowering process, however, consisting of small wells relatively close together, is a system that may be relied on under difficult conditions to solve this problem of draining dense sand successfully. This system was developed in Germany and the United States of America, and was introduced to this country only within the last few years. It originated in the step-wise system, which required that the excavation be done in lifts of some 16ft. to 18ft., or the depth that pumps could deal with reliably by suction. The initial step was to sink 3in. diameter vertical pipes about 40ft. apart along the line of the excavation. The pipes were perforated at the lower end and guarded with a fine gauze screen, and connected to a horizontal suction pipe which was attached to a pump on the ground surface. By this means it was possible to reduce the water down to a workable level of some 16ft. If the depth of excavation required three sets of suctions, giving a depth of, say, 48ft., the first set of pipes were placed about 60ft. back from the edge of the excavation. When the excavation of the first 16ft. was removed on a 45 deg. slope, a further series of vertical pipes were sunk at the foot of the slope about 18ft. nearer the pocket to be excavated, and the ground was left with a 45 deg. slope backwards to the upper row of vertical pipes. The second tier of pipes was connected as before to a horizontal suction pipe coupled to a second pump on the first stage level. The excavation was then taken down a further 18ft. At the foot of the new slope a third series of vertical pipes were sunk and coupled to a third horizontal suction pipe and pump on the second stage level. By this method it was possible to take out the excavation to the natural slope of the ground and thoroughly drain the water. Figs. 1 and 2 show the step-wise system as applied to the foundations of a museum in Berlin. The inconvenience of this system, however, arises from the necessity to take the work out in steps, which required sufficient room for a safe slope, or a very much wider trench with benchings for each series of suction pipes.

The new system, which has been introduced to this country by Messrs. Siemens BauUnion, and is now being handled through their agency along with Edmund Nuttall, Sons and Co. and John Mowlem and Co. (Joint), Ltd., consists of sinking pipe wells to the full depth required from the ground surface, in which centrifugal pumps are suspended to discharge the water. A pipe of sufficiently large diameter to provide for the pump and filter, say, 20in., is sunk for the full depth, and if the depth is too great

to be taken with one length of 20in. pipe, then the first sinking is done in a 24in. pipe or larger, as required. Finally, however, a 20in. pipe reaches the bottom of the well to give room for the necessary filter and pump. In this well is lowered a 14in. pipe, the bottom length of which is perforated with fine herring-bone saw-cuts around which is wrapped extremely fine wire mesh. Around this length of sieve are placed graduated pebbles between the 14in. and the 20in. pipes to build up an efficient filter. Well-worked puddle is then dropped between the two pipes on top of the pebble filter, and the entire space between the pipes is filled with puddle during the process of extracting the 20in. pipe, the clay being well rammed to fill the annular space as the pipe is removed.

---

* Read before the British Section, Société des Ingenieurs Civils de France on Tuesday, 24th October, 1933.

Should it be necessary to drain more than one layer of water-bearing sand, a second section of perforated pipe is inserted at the proper level in the 14in. line, with a filter of stones around it as before, resting on the puddle bed between the two filters.

A vertical centrifugal pump is then lowered into the 14in. well until it is suspended within the filter. When the pump is put into operation it withdraws clear water without the inflow of sand, and consequently forms an inverted cone in the reservoir of water which has to be drained.

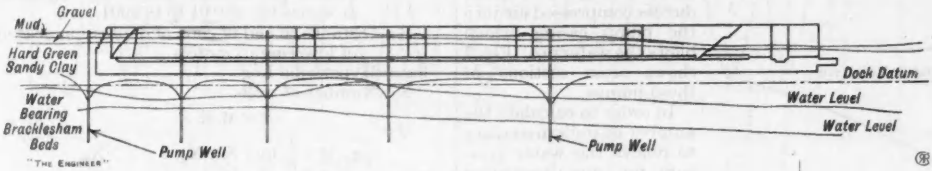

FIG. 5—LONGITUDINAL SECTION OF SOUTHAMPTON DRY DOCK WITH WELLS AND WATER PRESSURE CURVE

Additional wells are sunk at the necessary distances apart, so that the work to be done is surrounded with wells, and as each pump comes into operation there is formed an inverted parabolic cone of depression in the water reservoir at every well. The distance apart of the wells is calculated so that the intersection of the cones of depression never comes above the bottom of the finished excavation.

The first application of this system in this country was for the excavation of the dry dock being constructed at Southampton for the Southern Railway Company, under the direction of their docks engineer, Mr. F. E. Wentworth-Sheilds, M. Inst. C.E., by Edmund Nuttall, Sons and Co. and John Mowlem and Co. (Joint), Ltd., the contractors.

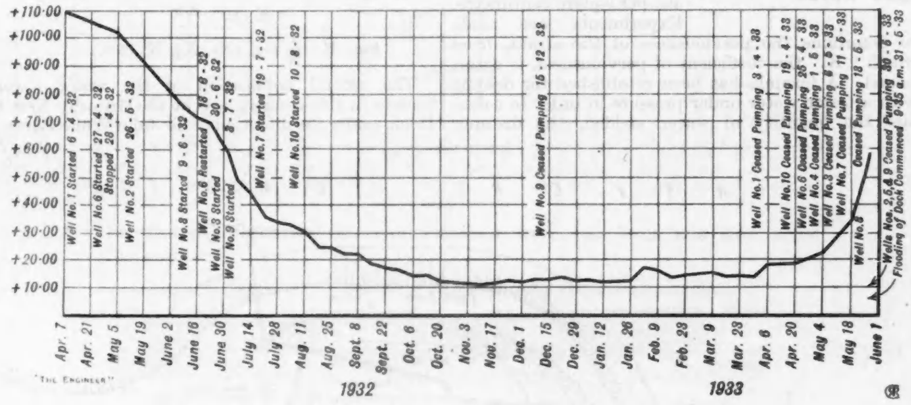

FIG. 6—EFFECT OF PUMPING AT SOUTHAMPTON DRY DOCK

In Fig. 3 is shown a cross section of this dock, with the relative positions of the wells on each side of the dock and the approximate curve of water pressure. Fig. 4 shows the plan of the dock and the positions of the bore-holes. Fig. 5 shows the longitudinal section with the wells and pressure curve of the artesian water.

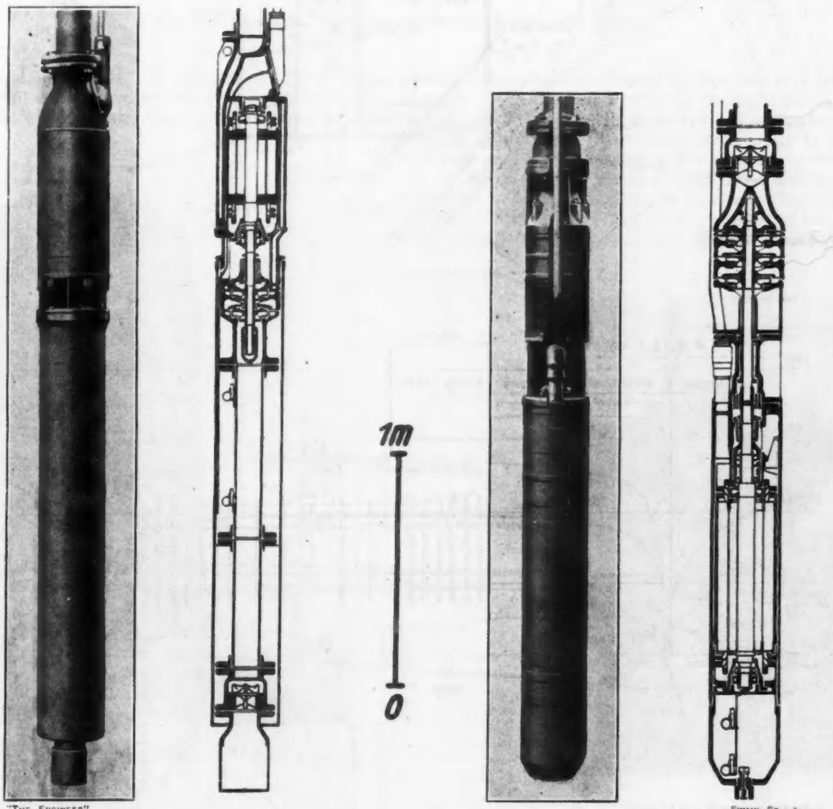

FIG. 7—CROSS-SECTION OF SUBMERSIBLE WELL PUMP, TYPES T-O AND T-U

The strata through which the excavation had to be taken varied, but generally consisted first of a bed of river mud of about 5ft., then a bed of ballast about 10ft. 6in., followed by a bed of hard green sandy clay varying from 70ft. to 100ft. thick, beneath which was a layer of sand and pebbles, commonly known as the "Bracklesham" Beds, containing artesian water, which rose to a height of 10ft. above the coping of the new dock. This represented a head of water of 94ft. at the underside of the invert of the dock, and 87ft. at the bottom of the dock wall.

Taking dock datum at zero, the coping was 100·00, the underside of the walls plus 23·00, and the underside of the invert in the centre plus 16·00. The artesian water rose to a height of 10ft. above the coping, or plus 110·00, and at the weakest point the underside of the bed of hard green sandy clay rose to plus 5·00, bringing the pressure of the artesian water within 18ft. of the bottom of the trench (as shown on the longitudinal section, Fig. 5), and within 11ft. of the bottom of the invert. This would have resulted, after excavation without lowering the artesian water, in an upward pressure on the underside of the trench of 1·95 tons per square foot, and on the underside of the invert a maximum of 2·36 tons per square foot, this being based on taking the water conservatively as dense as sea water at 64 lb. per cubic foot, and the hard green sandy clay at 130 lb. per cubic foot, which was determined by actual experiment.

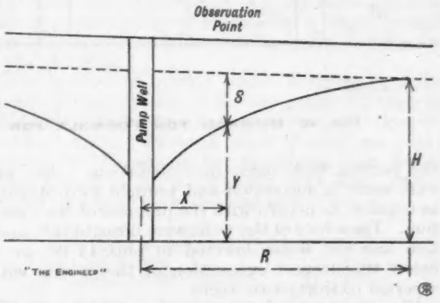

FIG. 8—DIAGRAM FOR FORMULA FOR GROUND WATER

In the trench 33ft. 3in. wide at the bottom, the layer of green sandy clay considered in the form of a concealed arch, would have been under a compressive force of 3·32 tons per square foot on the clay. If it is considered as a plug being forced upwards, there would have been a shear of 1·80 tons per square foot on both sides of the trench.

It is possible if the ground had remained dry that the trench might have withstood the upward pressure. In the case of the invert, however, much greater loads would have been experienced. As a concealed arch the compression on the clay under the invert would have amounted to 63·72 tons per square foot, and taken as a plug the shear on each side would have been 8·37 tons per square foot. Obviously, this would have given way under the pressure, and the walls being already built before the removal of the dumpling excavation, would have undoubtedly slid inwards. In fact, had it not been for the water lowering process, probably the dock, for a considerable length, would have had to be constructed, both as to walls and invert, by the monolith system at a greatly enhanced expenditure. Mr. Wentworth-Sheilds, consequently, determined that in order to carry out the work safely, the water-lowering system should be adopted.

FIG. 9—WELL SINKING AT SOUTHAMPTON DRY DOCK

Ten 20in. wells were sunk around the landward end of the dock as shown on Fig. 4, along with ten observation borings, 8in. diameter, for observing the water levels. Sounding pipes 2in. diameter, perforated at the bottom length and surrounded with a fine gauze screen, were placed inside the 8in. pipes, and a filter of graduated pebbles was made between the two pipes. After filling the annular space above the filter between the two pipes with clay, the 8in. pipes were withdrawn. An electric sounding apparatus was lowered down the 2in. pipes to obtain the water levels. The effect of pumping in the different wells is shown on Fig. 6, where the average head of the water is given week by week, with the dates on which the various wells came into operation. The wells were sunk in succession and brought into operation as required to accord with the progress of the excavation. The whole of the wells were brought into operation and the water lowered to plus 14·00, or 2ft. below the deepest excavation of the invert, within a period of thirty-two weeks.

Fig. 10—Diagram for Formula for Artesian Water

The water was lowered without drawing in any sand from the "Bracklesham" Beds, discharging from the wells in a clear stream suitable for drinking, tasting like chalybeate spring water. The maximum amount of water pumped to effect the lowering of the artesian water referred to was only 60 gallons per pump per minute, or 600 gallons in all.

The wells were coupled on each side of the dock to a discharge main, which carried the water over the dam into the river. In order to guard against any undue uplifting pressure on the completed dock when it is empty, Mr. Wentworth-Sheilds arranged for the wells to be cut off at plus 60·00, so that when the pumps are removed the artesian water will be relieved at this level through horizontal pipes with flap valves passing through the dock walls.

There are two types of vertical centrifugal pumps used for this work, viz., the T–O type with the motor above the pump, and the T–U type with the pump above the motor.

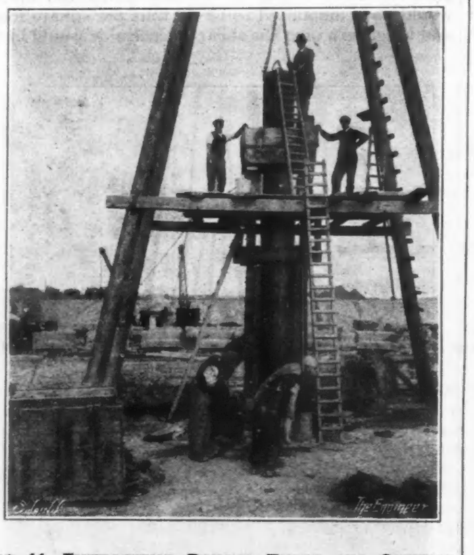

Fig. 11—Extracting Boring Tubes and Setting Filters at Southampton Dry Dock

The T–O form of pump was the first to be developed, and can be fitted with a lengthened suction pipe if necessary. The discharge water passes around the motor in a jacket cast outside the motor casing. One benefit of this pump is that it can be lowered to the very bottom of the bore-hole if required. The disadvantage of this T–O type of pump is that it has not been possible to make a T–O pump of this design that will work satisfactorily against a head of water greater than 98ft. It is also an exceedingly difficult pump to manufacture, and the motor is very inaccessible. The weight of the armature and the impeller have to be supported on a foot-step bearing, which adds to the difficulties.

The later type of pump, which is called the T–U pump, has the pump above the motor, and is of a smaller diameter than the T–O type. It deals with a much greater depth of water than the T–O pump, as it operates satisfactorily while discharging against a head of 328ft., and is, consequently, suitable for deep mining shafts and oil wells. The reaction of the pump impeller helps to carry the weight of the spindle and armature. As there is always a slight leakage of water into the motor casing from the gland, the casing is kept charged with compressed air. Should the water rise above a predetermined point in the casing, electric contact is made and a bell rings in the engine-room, indicating that that particular pump requires attention. The attendant, by touching a button, directs compressed air into the pump casing, which blows the water out. Fig. 7 shows cross sections of these pumps.

In order to calculate the number of wells necessary to relieve the water pressure for any particular job, certain particulars are required as to the density and size of the grains of the sand which is charged with water. Samples of the sand are obtained from a trial boring, and the grains are examined under a microscope to determine how many grains there are per square centimetre. Experiments are made to determine the perviousness of the strata, from which "K," the coefficient of perviousness, is determined. A formula has been established for dealing with artesian water under pressure in order to calculate the quantity of water yielded, the distance between the wells, and the amount the water pressure will be lowered.

"The Engineer"

Fig. 12—Grimsby Dock Plan showing Wells and Observation Tubes with Cross-Section

Fig. 10 shows a typical cross section with the necessary symbols required in the formula, as outlined here :—

Q=Quantity of water pumped in cubic metres per second.

S=Depth that artesian water has to be lowered in metres.

X_1, X_2, &c., are horizontal distances of pump wells from observation points.

M=Thickness of water bearing (artesian) strata in metres.

K=Coefficient of perviousness of the strata in metres per second, based on experience. It varies from 0·01 to 0·0001.

R=Distance to end of cone of depression or range of lowering in metres.

$\log_e$=Hyperbolic Log.

N=Number of wells.

$$Q=\frac{2\pi MKS}{\log_e R-\frac{1}{N}\log_e X_1, X_2, \ldots X_n}$$

Where ordinary ground water has to be dealt with, the formula is slightly different. Fig. 8 gives a diagram showing the symbols in the formula, which are as follow :—

Q=Quantity of water pumped in cubic metres per second.

K=Coefficient of porosity of the strata.

H=Depth of water-bearing ground.

S=(H—Y) Lowering of water at observation point.

X=Distance from well to observation point.

$$Q=\frac{\pi K(H^2-Y^2)}{\log_e R-\frac{1}{N}\log_e (X_1, X_2, X_3, \&c.)}$$

The second application of the water lowering process in this country was at the Grimsby New Fish Dock, under the direction of Sir John Wolfe Barry and Partners, the water lowering being carried out for the contractors constructing the dock and lock—Sir Lindsay Parkinson and Co., Ltd.—by Edmund Nuttall, Sons and Co. and John Mowlem and Co. (Joint), Ltd.

On Fig. 12 is shown a plan of the entrance lock for the New Fish Dock, with the position of the wells and observation tubes, along with a cross section giving the curves of water pressure after the pumps were in operation. Six pump wells were sunk and ten observation wells. These observation wells were sunk first to determine the best location for the pump wells. The strata was proved in this way to vary considerably, and the wisdom of thus selecting the points for the pumping wells was justified, as it was found that towards the south-easterly part of the lock the impervious clay rose about 29ft., the water-bearing strata consequently sloped from a thickness of 30ft. on the west to only 3ft. thick on the east side. In this case, although the water was artesian, its pressure was directly affected by the rise and fall of the tide. Fig. 13 shows that the fluctuations in the various observation wells synchronised with the rise and fall of the tide. The observation wells 1, 2, 3, and 8 show much higher water levels than the others on account of the clay strata at that point holding up the water. Dock datum in this case was 67ft. below cope level, the greatest depth of excavation for the lock being plus 16·00, and the general foundation level being plus 24·50. Generally speaking, the water level was kept below plus 20·00. It is of interest to note on this typical weekly diagram that during all week-ends, in this case May 27th, 28th, and 29th, the water level rose about 3ft. and then fell on the 30th, resuming the old level. The reason for this was discovered to be due to the factory wells in the district, which draw their water from this artesian reservoir, shutting down their pumps over the week-end, thus allowing the water to accumulate. To maintain a lower level additional wells would have been necessary.

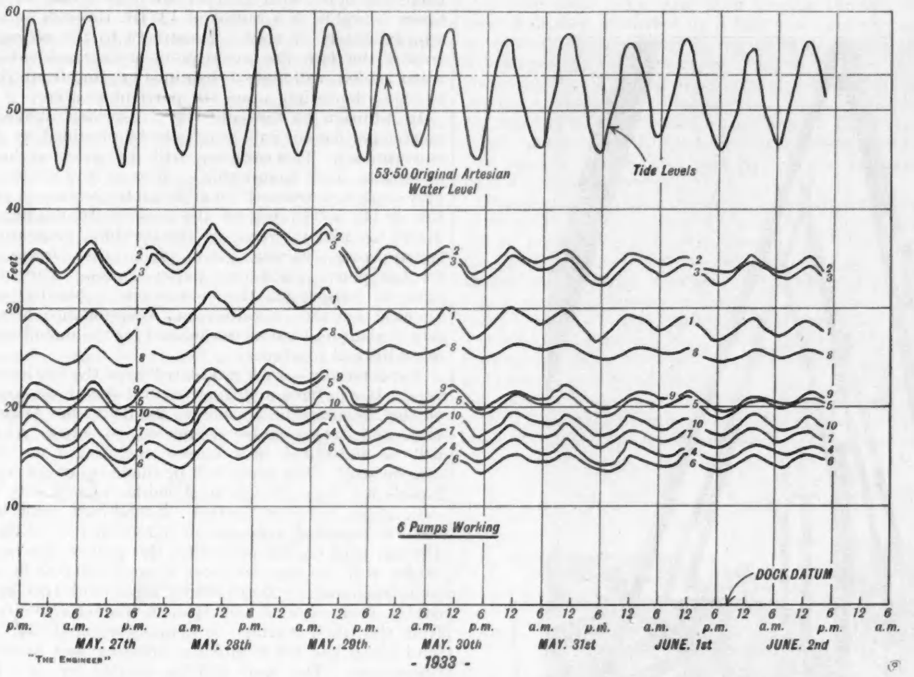

Fig. 13—Water Levels at Grimsby showing Rise and Fall for One Week

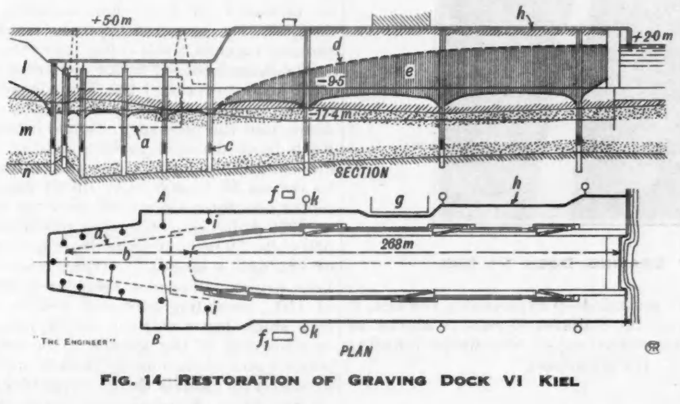

Fig. 14—Restoration of Graving Dock VI Kiel

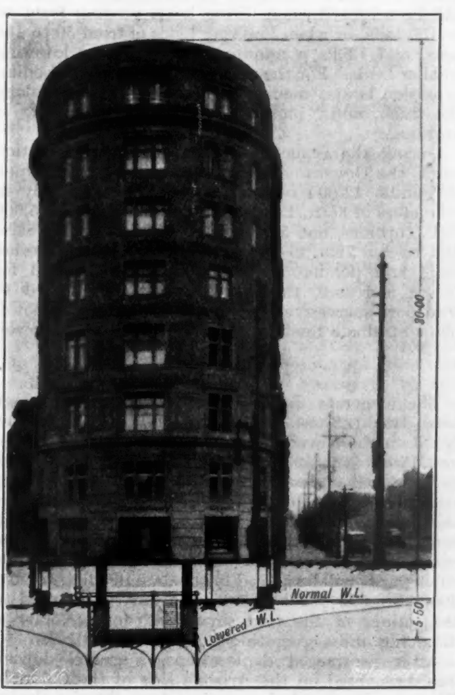

Fig. 15—B.U.R.—Construction of a Deep Basement under Existing Building

In constructing the work the engineers and contractors had not anticipated that there would be a sufficient upward water pressure in the sand and gravel to lift the intervening bed of brown warp, which is some 20ft. thick, to the underside of the lock. The trench for the west wall, enclosed in steel sheeting, had been excavated, and part of the concrete wall had been constructed supported on timber piles, when a "blow" occurred at the southern end. The "blow" resulted in a considerable inflow of sand, which caused a settlement of the concrete west wall already built and serious breaks in it, this in spite of the fact that the wall was carried on timber piles. Work was suspended until the water lowering pumps were in operation. When the part of the wall which had subsided had been removed it was found that the piles had lost their set, and it was necessary to re-drive them before replacing the wall. Since then both walls have been constructed and no further movement has been observed apart from a slight inward movement of the toe of the wall during the excavation for the dumpling.

This method of ground water lowering by submersible pumps in deep wells was originally tried in 1927 on the Continent with great success. The deepest lowering depths obtained were during the construction of the sluices for the North-East Canal (Kieler Kanal) in North Germany with 72ft. Other remarkable depths were obtained as follows :—

Southampton Dry Dock	96ft.
North Lock, Bremerhaven	66ft.
Sea Lock, Emden	63ft.
Sea Lock, Ymuiden (Holland)	66ft.

The construction of a tunnel under the Spree for the Underground Railway of Berlin was interesting, in that the tunnel was built in two sections, each section being shut off against the water of the river by double sheet pilings filled between with sand. After the completion of the enclosing dam for the left section out to the middle of the river deep wells were installed inside the cofferdam, and the ground water under the bottom of the river bed was so effectively lowered that the excavations could be proceeded with in completely dry ground as if there had never been any ground water pressure. The second half of the tunnel was dealt with in the same way as well as the approaches. The effect of the water lowering was that the time required was considerably shortened. Here the lowering depth was 40ft. below the bottom of the river bed.

Since 1927 the extension of the Berlin Underground Railway has been carried out by means of the ground water lowering system, more especially in the centre of the town, where the tunnels had to be built under blocks of houses—see Fig. 15.

The ground water lowering method was also successfully applied where damaged buildings have to be restored, and the deep well lowering showed its many advantages. The restoration work at No. VI. Dock in Kiel—see Figs. 14, 16, and 17—which showed fissures in the side walls and the bottom, the side walls having sunk considerably, was carried out under the protection of the ground water lowering process. This restoration scheme provided for the interior of the dock being lined with reinforced concrete, which was fixed to the walls by means of iron braces. As several springs carrying sand rose from the dock bottom during ordinary pumping operations, the ground water lowering plant was installed and completely removed this danger.

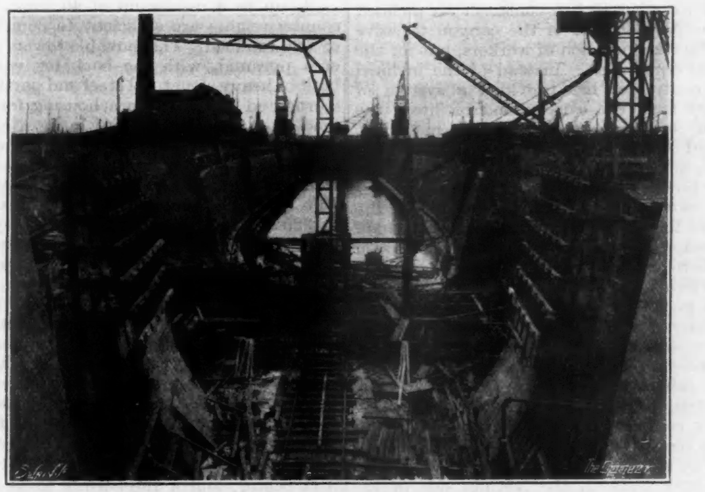

Fig. 16—Restoration of Graving Dock VI Kiel

In Bremerhaven the construction of the North Lock and the extension of the Kaiser Dock II. were carried out with the water lowering process. Here an impervious layer of clay reaches to a depth of 60ft., and below the clay there is a layer of sand of varying thickness from 1ft. to 20ft. under artesian water pressure. The foundation of the lock heads and the dock extension rested on this layer of sand. Sufficient reduction of the artesian pressure was achieved so that the whole of the work could be executed without difficulties arising from the water pressure.

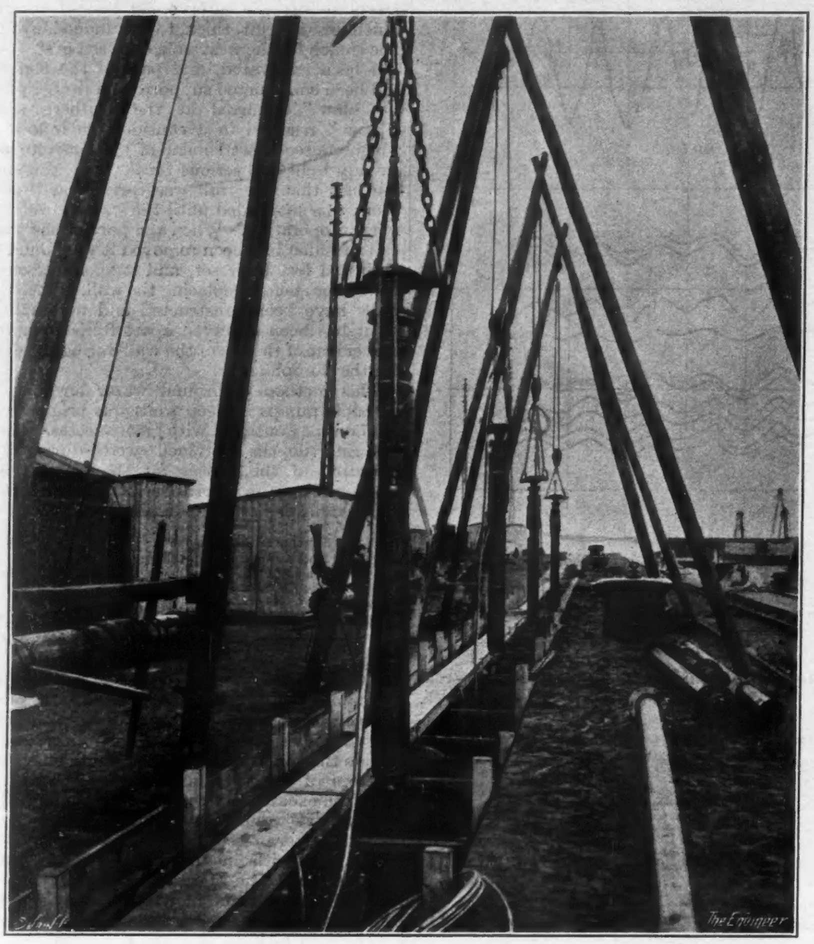

FIG. 17—WATER LOWERING PUMPS FOR RESTORATION OF GRAVING DOCK VI KIEL

There are other examples which might be mentioned, but sufficient have been described to show that the water lowering process by deep well pumps in one stage is a successful means of overcoming what formerly constituted a serious difficulty in constructing heavy civil engineering works.

In future, by a careful study of the geological strata supplemented by several deep exploratory borings, it will be possible for the engineer to remove all risk of "blows" by the utilisation of this water lowering process.

(To be continued.

The Hoover Dam on the Colorado River.

No. II.

(Continued from page 376, October 20th.)

CABLEWAYS.

BEFORE Six Companies, Incorporated, started operations the plan was to construct an inclined railway on the Nevada side of the canyon to serve not only for the transporation of workers, but for the handling of all equipment. Instead of the inclined railway, the contractor has provided a system of cableways that span the canyon and facilitate the transportation of workers, structural materials, machinery, and equipment of various kinds. Caterpillar tractors, heavy motor trucks, and considerable parts of large power shovels have thus been lifted or lowered and moved from point to point. In the earlier stages of the operations in Black Canyon small service cableways were erected near the diversion tunnel portals to move heavy equipment across the river, to build temporary steel suspension bridges, and to carry men to points where they could do scaling work on the canyon walls. Later on, these cableways were utilised in erecting Stoney gates, steel bulkhead gates, and the foundations for trash racks. Still another small cableway was thrown across above the valve house sites, and has served to transfer men and materials from rim to rim of the canyon and also to carry them to the valve house sites. All these cableways are of the stationary tower type, having their hoists and power units on the Nevada side of the canyon. To cover the sites of the spillways intake, towers, and dam, Six Companies, Incorporated, has installed five 20-ton cableways. These cableways have self-supporting movable towers at the head ends of four of the units and at the tail ends of all five. They are situated at strategic positions and make all parts of the working area accessible.

The track cable for each installation is of the lock-coil type, 3in. in diameter, and capable of carrying 450 tons. The endless rope is a steel cable 1in. in diameter and the hoist and dump ropes are ⅞in. in diameter. The cableways have been designed for normal operations not requiring loads of more than 20 tons, but they are capable of handling infrequently loads up to a maximum of 40 tons. The concrete counterweights are sufficient to counteract the pull of a 60-ton load. The movable towers are in the form of a pyramid, with the back leg vertical, and are built of heavy structural steel and partly covered with corrugated iron to form a housing for the operating machinery. The floors are built of chequered steel plate. In order to eliminate the risk of fire no wood is used in the structures. The towers vary in height from 17ft. to 90ft., their widths range from 20ft. to 46ft., and their lengths along the track are from 20ft. to 32ft. The towers are supported by from four to eight trucks, and each truck runs on two pairs of wheels, 33in. in diameter, travelling upon two parallel standard-gauge tracks placed between 19ft. and 45ft. apart. The vertical component of the pull of the cable on each tower is resisted by a massive block of concrete weighing from 400,000 lb. to 1,052,000 lb., placed above the rear trucks. The horizontal component of the cable pull is counteracted by trucks on the tower bearing against a centre rail placed with its web horizontal or by elevating the front rail of the front track.

Each cable is operated by a 500 H.P., 2200-volt A.C. motor, and a three-drum hoist equipped with band brakes and V-type wood-block clutches. The brakes are actuated by compressed air. Safety features are provided whereby the brakes are applied automatically in case of power failure, overloading, overspeeding, or by reason of the incapacity of the operator. The load can be conveyed on the track cable at a rate of 1200ft. per minute, and lowered or hoisted at a speed of 300ft. per minute. A tower is moved on its tracks by a motor and hoist in the structure—the hoist being attached by a single cable and through sheaves to an anchorage at each end of the track runway. A single electrical circuit, operated from the head tower, synchronises the movement of the head and the tail towers. Two of the cableways have a span of 1405ft.; two others have a span of 2575ft. The fifth cableway is of the radial-travelling type, with its head tower fixed and its tail tower movable at a radius of 1374ft. through an arc approximately of 600ft. Relatively to the ultimate crest of the dam, the lowest point of the track cables, when loaded, will have a clearance varying from 57ft. to 88ft., depending upon the particular cable.

In addition to the cableways described above, a master permanent cableway is to be provided by the Government. This cableway will, it is asserted, have a capacity more than twice as large as any cableway previously constructed. In addition to the transportation of the steel pipes for the pressure tunnel lining, it will be used to transport the turbines, generators, transformers, valves, gates, and other materials for the power plant and outlet works. After the dam is completed, the permanent cableway will be used for the operation and maintenance of the power plant and outlet works, and for the installation of additional machinery.

The cableway—see Fig. 11—will be of the stationary type. It will have a 90ft. structural steel head tower on the Nevada side, a concrete saddle on the Arizona side, and track cables connected to I-bars which will be imbedded in concrete anchorages in each canyon wall. The track will be made up of six 3½in. Lang's lay superplough steel cables placed side by side, 18½in. between centres. Each track cable will have a breaking strength of 1,700,000 lb. With a 150-ton load on the cableway, the pull of the track cables will amount to more than 2,000,000 lb. on each anchorage. Two endless ropes and two hoist cables, each of steel and 1⅛in. in diameter, will run from the track carriage to drums for conveying the load along the track and for lowering and hoisting operations. The load will be carried by two fall blocks which will be suspended from the track carriage by a reeving of hoist ropes. The track carriage will be mounted on forty-eight sheaves, each 24in. in diameter, for travelling upon the track, eight sheaves running on each track cable.

The hoist house is under construction between the steel head tower and the Nevada anchorage. It is to accommodate two hoist drums, one conveying drum, and the necessary electric power control units. Each hoist drum is to be operated by a 125 H.P. direct current motor, while the conveying drum will be driven by a 400 H.P. direct current motor. A motor generator set will convert the received current at 2300 volts and 60 cycles into working current at 550 volts. The conveying drum is to have a diameter of 8ft. and a length of 10½ft., and each of the two hoist drums will have a diameter of 13ft. and a length of 17ft., providing sufficient area to wind the ropes in a single layer without overlapping. Deceleration and braking of the load is to be secured by motor control and operation, by brakes on the hoist drums actuated by electric thrustors and by solenoid brakes on the axles of the driving motors. Equipment is to be provided whereby the load will be automatically decelerated and brakes applied in the event of overloading, overspeeding, or power failure. It will be possible to operate the track carriage at a speed of 240ft. a minute. A speed of about 30ft. a minute will be achieved when lifting loads ranging from 40 to 150 tons, or when lowering loads of from 50 to 150 tons, and 120ft. a minute when lifting or lowering smaller loads. For the nice handling of heavy bodies, provision is also made for "creeping" speeds along the track, and "inching" speeds when hoisting or lowering.

During the remaining years of the construction work, the Government cableway will be called upon to handle 42,000 tons of steel pipe, principally in diameters of 8½ft., 13ft., 25ft., and 30ft., four 115,000 H.P. turbines, one 55,000 H.P. turbine, twelve 84in. and twelve 72in. needle valves, and numerous other large and ponderous details. As the demand for power increases, the cableway will be utilised to transport successive generator units until the power plant attains a final rating of 1,835,000 horse-power.

TRASH TANKS.

The concrete foundation for the 100ft. high trash track at the inlet portal of Diversion Tunnel No. 2 on the Nevada side of the canyon was poured on March 5th, 1932. This concrete was the first to be placed under the general contract for the construction of the Hoover Dam, the power plant, and the appurtenant works. Before the undertaking is completed, approximately 4,400,000 cubic yards of concrete will be poured. Of this volume, 3,400,000 cubic yards will be placed in the dam itself. Already, 300,000 cubic yards of concrete have been used in the linings of the four diversion tunnels, 50ft. in diameter, and aggregating 15,934ft. in length.

After protracted explorations, a gravel deposit was discovered on the Arizona side of the Colorado River 6 miles north, by air line, from the site chosen for the dam. The deposit lies along the river, covers an expanse of more than 100 acres, and has an average depth in excess of 30ft. The choice was made after testing gravel from more than a score of deposits lying within a radius of 50 miles from the dam site. Care in the matter was essential because the specifications prescribed that mass concrete should have a compressive strength of 2500 lb. per square inch, and that thin concrete sections should have a compressive strength of 3500 lb. per square inch. The aggregates, composed of sand and gravel, are excavated from the Arizona deposit by a 5 cubic yard electric drag-line, dumped into 50-ton side-dump cars, hauled across the Colorado River on an 850ft. pile-trestle bridge, and carried thence by railway to the screening plant 6 miles distant. At that point the material is dumped into bunkers from which it is transported by belt conveyors to rotary and vibrating screens that separate the pit material into sand and into four sizes of gravel. Thereafter, another series of conveyors deposits the different products into so many stock piles. The sand and each size of gravel are loaded by belt conveyors into separate railway cars and hauled 4·7 miles to the concrete mixing plant, known as Lo-Mix Plant, situated in Black Canyon about a mile upstream from the dam site. The Arizona gravel deposit is worked continuously in three shifts daily, and the average output per day varies between one hundred and fifty and two hundred 50-ton carloads. The screening plant is situated in a flat area 2 miles west of the river in Hemenway Wash, and is at what is known as Three-Way Junction, on the contractor's railway, where a branch connects with the United States construction railway that runs to Boulder City—see map, Fig. 2, in our issue of December 9th, 1932.

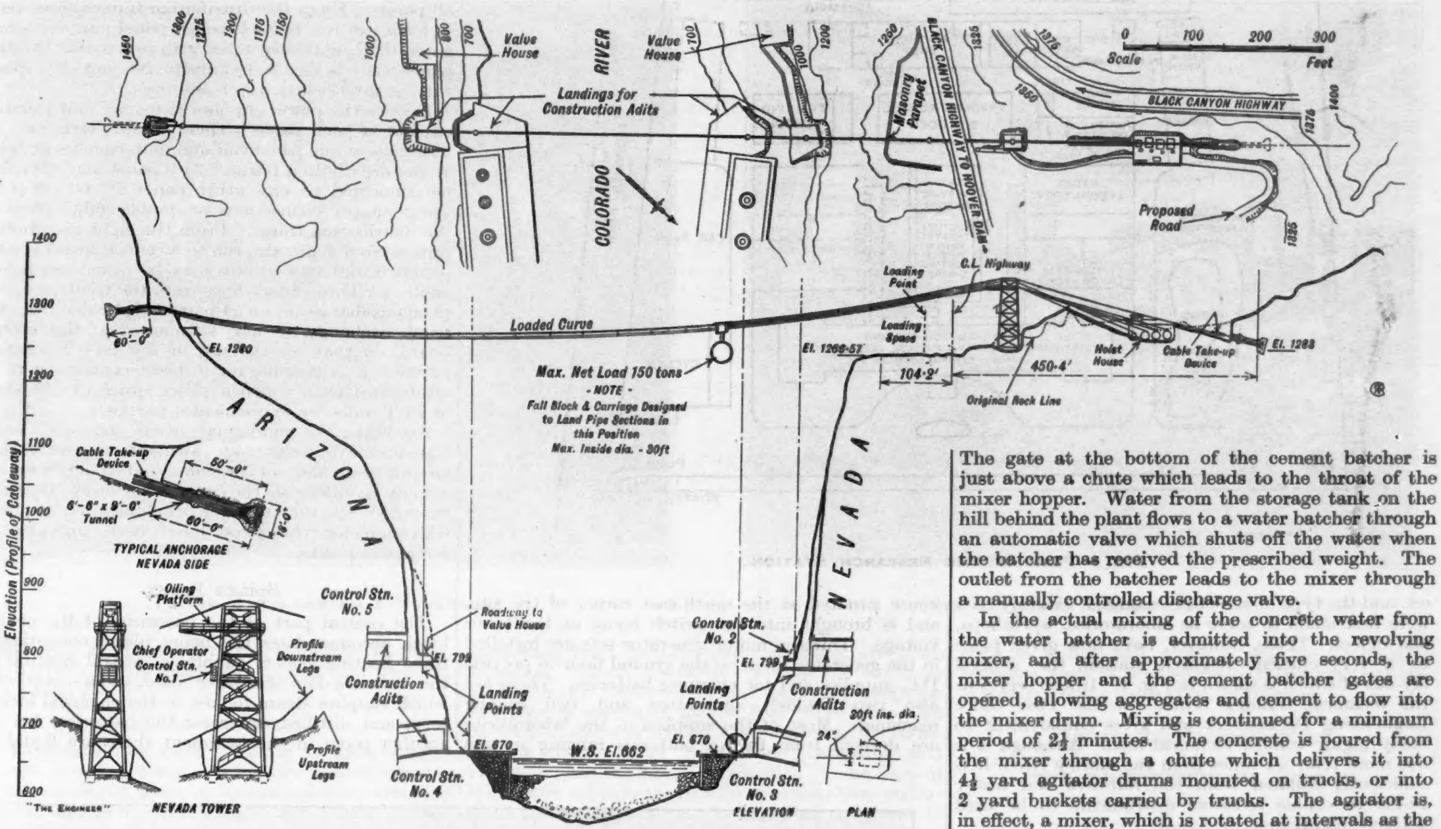

Fig. 11—The Permanent Cable Way

Screening and Washing Plant.

The screening plant consists principally of a crusher, four classification towers, a sand washer, a sand shuttle conveyor, four storage piles, and sand storage piles. A 42in. belt conveyor, running beneath the raw storage bunkers, moves the material and dumps it into a 20ft. cylindrical revolving screen. This screen permits all material of less than 9in. in maximum dimensions to pass through it, and dumps cobbles above this size on to a transverse conveyor that feeds a gyratory crusher. The output from this crusher is returned by suitable conveyors to the screen. Material of less than 9in. size is fed to a 36in. belt conveyor, which delivers it to the first classification tower in which there are two vibrating screens. The first screen allows aggregates of less than 3in. in size to pass and dumps material ranging from 3in. to 9in. on to a transverse conveyor which moves the stuff to a stock pile. The second screen passes sand and material of less than ¼in. in size through its perforations, and dumps all gravel on to a lateral conveyor that runs to the second classification tower. In a similar manner the vibrating screens and transverse conveyor at this second station remove the 1½in. to 3in. gravel to a stock pile, and the lateral conveyor transports material of less than 1½in. in size to the third tower. Here, gravel of ¾in. to 1½in. size is removed to a stock pile, and all materials that pass through the screen are conveyed laterally to the fourth tower, where a transverse conveyor carries the gravel of ¼in. to ¾in. size to its stock pile.

The sand removed by the vibrating screens in the first classification tower is delivered by chute to a series of mechanical sand washers or classifiers. The water and silt separated from the sand overflows through a flume to a sedimentation tank equipped with a classifier and sludge pump. The water from this classifier is delivered to a sump tank and then pumped to a sedimentation tank on an adjacent hill and is re-used. The sand after passing through the second washer is carried by a belt conveyor through a concrete tunnel beneath the railway tracks and discharged on to a conveyor running parallel with those tracks. This conveyor connects with a tripper serving two transverse conveyors. By these means the sand may be piled on either side of the lateral supply conveyor and parallel with the railway tracks. The sand is loaded into cars by a crane equipped with a clam-shell bucket.

The screening plant has a capacity of something more than 500 tons an hour, and four 50-ton cars can be loaded every sixteen minutes. By increasing the speed of the conveyor belts and making slight alterations in other directions, the capacity of the plant can be increased to 1000 tons an hour. The plant is run by electric power, and is controlled from a central switching station. Thirty-four sets of push-button switches control all the units of the plant, and one switch can stop all operations. Water for washing purposes is pumped from the Colorado River, by stages, through 2 miles of 12in. pipe, against a static head of 415ft., to a sedimentation tank on a hill south-east of the plant. The character of the silt in the river water is such that 98 per cent. of it can be removed by a detention period of three hours in the tank. Water from the river contains an average of 6000 parts per million of silt, and water, sent to the screening plant, must not have more than 500 parts per million. The pre-sedimentation tank, constructed of reinforced concrete, is 150ft. in diameter and 15ft. high. It has a capacity of 800,000 gallons, and is equipped with a clarifier. Sludge is removed by gravity. The screening plant represents an outlay of about 450,000 dollars.

Concrete Mixing.

The Lo-Mix plant occupies a natural shelf at the foot of the canyon wall, which was enlarged to provide accommodation for a structure 78ft. wide and 118ft. long in plan. The plant is 88ft. in height from the truck-loading platform to the top of the storage bins. The bins at the top of the plant are six in number—three for gravel, one for cobbles, one for sand, and one for cement. They are of steel-frame construction with laminated timber sides and partitions. The walls are of 3in. by 8in. to 3in. by 12in. planks, and the floor is of 3in. by 16in. planks. The cement bin is covered and is waterproofed on the inside with tar and felt. Cement is delivered in bulk and transferred from the cars to the bin through a 6in. steel pipe pneumatically by two 40 H.P. Fuller-Kinyon pumps. The water used at the mixing plant is pumped from the river to a clarifier 50ft. in diameter, situated on the canyon wall a quarter of a mile farther upstream. All silt in excess of 500 parts per million is settled out in this tank, and the water flows thence by gravity to a 125,000-gallon storage tank set up in a side canyon above the mixing plant.

The mixing plant at present contains four 4 cubic yard tilting mixers, but at peak production it will probably have in service four more mixers of the same capacity. In addition, there are two batchers for each mixer for water, cobbles, sand, and gravel, and four batchers for cement. Each batcher alternates in serving two mixers, and is provided with a weighing, cut-off, and recorder beam, and a full-capacity dial above the beam box. The plant contains two supply conveyors capable of moving 1500 tons of aggregates an hour. The storage bins have a total capacity of 5400 cubic yards of aggregate and the equivalent of 14,800 barrels of cement. The principal power equipment consists of 75 H.P. motors for each mixer, and 200 H.P. motors for each of the supply conveyors. When in operation, sand and gravel of the prescribed sizes are dropped through an automatically controlled gate and discharged into a batcher placed below each bin. Doors in the bottom of the batchers are opened in rotation by air-controlled, electrically operated apparatus, and the aggregates are spread in thin layers on a 48in. belt conveyor that leads to a mixing hopper above and behind a mixer. When the 3in. to 9in. cobbles are used, they are released through a door in the bottom of the cobble bin and drop on to an automatically controlled steel belt conveyor and go to the cobble batcher. For each mixer, cement runs from the cement bin through four chutes to an automatically controlled, double-screw-conveyor cement feeder, placed at the top of the cement batcher.

The gate at the bottom of the cement batcher is just above a chute which leads to the throat of the mixer hopper. Water from the storage tank on the hill behind the plant flows to a water batcher through an automatic valve which shuts off the water when the batcher has received the prescribed weight. The outlet from the batcher leads to the mixer through a manually controlled discharge valve.

In the actual mixing of the concrete water from the water batcher is admitted into the revolving mixer, and after approximately five seconds, the mixer hopper and the cement batcher gates are opened, allowing aggregates and cement to flow into the mixer drum. Mixing is continued for a minimum period of 2½ minutes. The concrete is poured from the mixer through a chute which delivers it into 4½ yard agitator drums mounted on trucks, or into 2 yard buckets carried by trucks. The agitator is, in effect, a mixer, which is rotated at intervals as the concrete is being transported, thereby ensuring uniformity of consistency and density. The buckets, two of which are transported on each truck, are of the bottom-dump type. While one batch of concrete is being mixed, another is discharged into the mixer hopper and the cement and water batchers are re-loaded. At full capacity, with all four mixers in action, 16 cubic yards of concrete can be produced by the plant in 3½ minutes.

The Lo-Mix plant will be dismantled and its equipment removed to amplify the high level, or Hi-Mix plant when the dam, with the water impounded by it, reaches a certain height. The Hi-Mix plant, on the Nevada side of the canyon, is already under construction, and after the dam has reached an elevation of 395ft. above the bed of the river, this plant will provide all the concrete for the completion of the structure. To begin with, this high-level plant is being equipped with two 4 cubic yard mixers.

(To be continued.)

INSTITUTION OF NAVAL ARCHITECTS.

The Council of the Institution of Naval Architects has made the following awards:—

Institution of Naval Architects Scholarship (1933), £130 per annum for three years at the Royal Naval College, Greenwich, to Mr. R. E. Tozer, of Devonport Dockyard.

Earl of Durham Prize to Mr. H. W. J. Chislett, of Devonport Dockyard.

Duke of Northumberland Prize (in connection with the 1933 examinations for National (Higher) Certificates in Naval Architecture) to Mr. Alexander Stewart, of the Technical College, Sunderland.

1851 Exhibition Commissioners Post Graduate Scholarship in Naval Architecture (1933), £250 per annum for two years, to Mr. H. J. Tabb, of the Royal Naval College, Greenwich.

Sir William White Post Graduate Scholarship in Naval Architecture (1933), £150 per annum for two years, to Mr. Will Pratt, B.Sc., of Durham University (Armstrong College, Newcastle-on-Tyne).

The Post Office Research Station.

ALTHOUGH the assertion that Great Britain lags behind others in the field of research may have been true a few years back, in some directions, at any rate, she now easily holds her own. It is doubtful, for instance, if a more elaborate or better equipped establishment devoted to electrical communication investigations can be found than the British Post Office Research Station at Dollis Hill, opened by the Prime Minister on Monday last. A site of 8 acres was purchased for the station in 1920, but as the cost of erecting buildings at that date would have been excessive, and as a certain amount of experience was desirable in order to be sure of the most suitable lay-out and the type of structure required, ex-army huts were first made to serve as laboratories, workshops, and offices. These, however, have now given place to a very efficient research station, the general lay-out of which is shown in Fig. 1. It also serves as the technical training centre for the Post Office Engineering Department and gives employment to many highly trained technical men. Although it is not more than six miles from the Marble Arch, it is sufficiently isolated from the railways and heavy traffic to enable sensitive instruments to be used without disturbance.

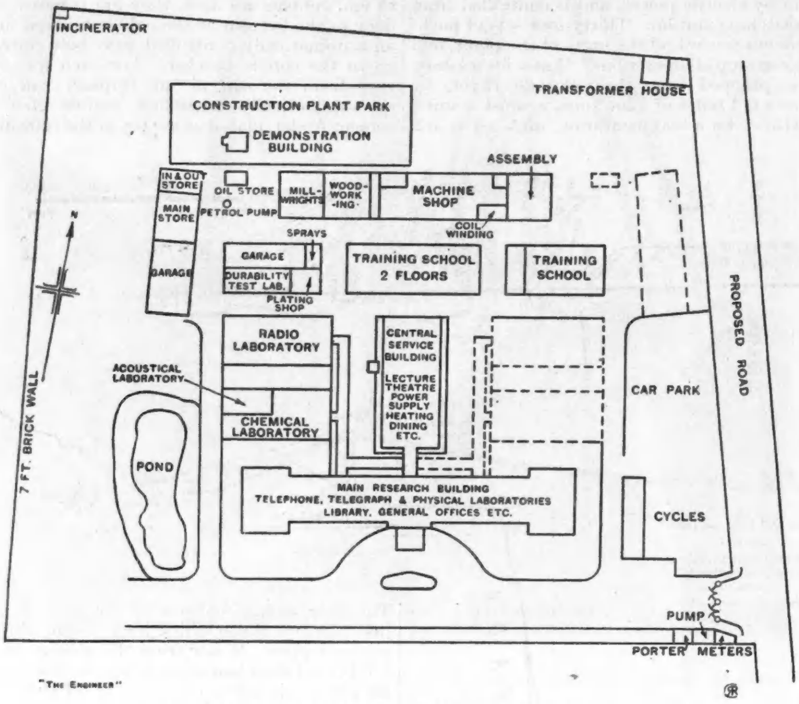

FIG. 1—PLAN OF THE RESEARCH STATION

BUILDINGS.

The main building with three floors contains offices and laboratories equipped with the most up-to-date apparatus, and in every way suitable for the work upon which the research staff is engaged. Situated on the ground floor, the offices serve for the administration and clerical staffs. At the western end of this floor there are laboratories for physical and special electrical tests, whilst the eastern end is devoted to work on exchange signalling methods and apparatus. At the western end of the first floor apparatus transmission measurements are made, and the specially silenced laboratories used for some of this work are ventilated by a system connected to the ventilating fleche on the roof. The laboratories at the eastern end at this level are used for research on line transmission problems, while telegraph laboratories occupy the western end of the second floor, which accommodates the library in the centre. At the eastern end there are laboratories for cable tests and records and for dealing with the development and construction of research apparatus. With the exception of two laboratories in the basement, three rooms of the second floor devoted to training, and the attic floor, the adjacent central block serves for the provision of services. The attic of this building, together with part of the attic floor of its research block, is occupied by photographic studios and dark rooms.

The main research block, consisting of a building some 286ft. long, with its three principal floors, stands on the crest of Dollis Hill, facing south. Attached to it on the northern side is the central block of similar height, and a number of independent single-storey laboratories east and west of the central block are connected with the latter and the main block by covered ways. Separated from the northern end of the central block by a roadway is the two-storey Automatic Training School building, and further to the north the workshops are accommodated in a building some 240ft. long and 40ft. wide. The remainder of the station northward is the Construction Park, laid out for research and training in connection with the various processes associated with the outdoor activities of the Post Office.

POWER SUPPLIES.

Electric power is supplied to all the laboratories from the central block by means of cables in horizontal ducts above the covered ways and above or below the corridors. Three-phase current purchased from the Willesden Borough Council on the maximum demand basis is supplied to the station at 2000 volts and is transformed down to 415 volts in a transformer house situated at the north-east corner of the site, and is brought into the switch house at the lower voltage. Thirteen motor generator sets are installed in the generator room on the ground floor to provide D.C. supplies and for charging batteries. There are also two Duddell alternators and two ringing machines. Most of the supplies in the laboratories are derived from twelve batteries ranging in size from 40 to 1000 ampère hours capacity. The lighting system is fed at 240 volts, but various pressures are, of course, provided for experimental purposes in the laboratories. The main cabling and laboratory wiring has been installed on the basis of a maximum drop between the battery and bench panel on all the main feeds of not more than 2 volts on circuits up to 100 volts and 5 volts on 100-volt circuits and over. For some of the laboratories, however, special batteries have been provided for ensuring a more constant pressure and are charged through rectifiers from the A.C. supply. A battery room is provided, for instance, adjacent to the lines transmission laboratory and is used in connection with repeater research. The batteries in this room are at present objects of research, as the electrolyte of various cells is covered with different kinds of oil in order to determine their relative values as regards preventing acid spray.

In detached buildings the supply cables are led to distribution cases, and distribution is provided from these to the laboratory points in the usual way. In the main research building the laboratories are grouped in eight main divisions, and in each division there is a main distribution frame, which is connected to the main switching point. Where a group of laboratories uses certain supply voltages regularly, leads providing these voltages are permanently connected to the distribution frame. In addition each laboratory is provided with spare feeders, which can be connected to supplies at different voltages as required. Each main feeder terminates on the frame bus-bars in jacks and the outgoing feeders from the frame to the bench panels also end in jacks. By the use of single-way double-ended cords and plugs connection can, therefore, be made from any supply to any bench panel. In the laboratories the cabling is run through floor chases and double-top benches so that convenient access can be gained to the cables at all points. From the distribution frames three pairs of feeds are run to each bench panel and are terminated there on fuse switches with terminals. On each panel there is also a 10-ampère 240-volt A.C. point with an interlocked switch and fuse.

Besides the power supplies there are four junction circuits at each panel. These circuits terminate on terminals at the panel end and on terminals or jacks at the distribution frame. Any panel may therefore be connected to any other panel of its group by using jumper connections or double-ended cords at the distribution frame. From the eight distribution frames circuits are also run to a central board so that panels in different groups may be connected to one another. Three direct lines from the Gladstone telephone exchange, and a 24-pair loaded cable from the trunk exchange, are also terminated at this central board, so that by the use of the inter-laboratory junction it is possible for a direct connection to be established from a bench panel either to Gladstone or to Trunks for experimental purposes.

According to individual needs gas and water supplies have been made available in the various laboratories, and air pressure and rough vacuum, already available in the older labortories, are being extended to the research building as required. Galvanometer brackets have been provided at numerous points.

BOILER PLANT.

The central part of the basement of the central block accommodates the boiler plant, consisting of three heating boilers supplying central heating for the station, a domestic water boiler, and a steam boiler which supplies steam for use in the chemical laboratory, and distilled water for the batteries, &c. In another room in the basement there are liquid air and ice plants and a vacuum pump, which provides the rough vacuum mentioned.

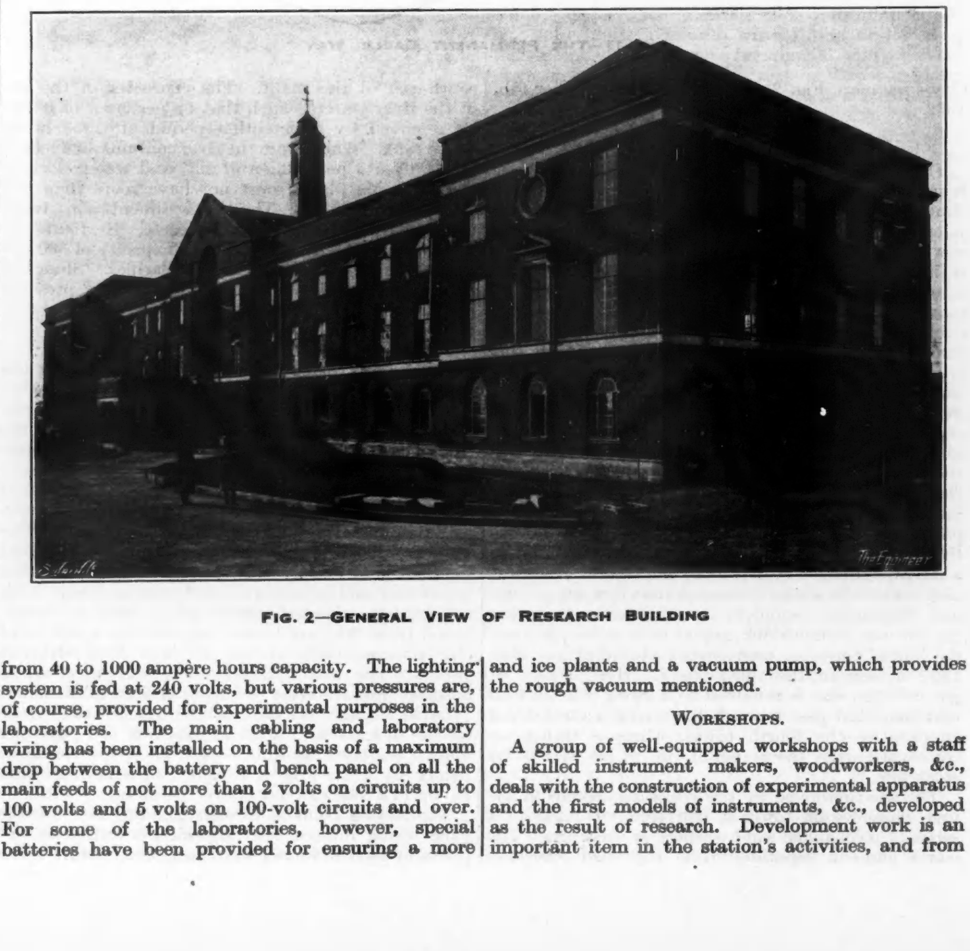

FIG. 2—GENERAL VIEW OF RESEARCH BUILDING

WORKSHOPS.

A group of well-equipped workshops with a staff of skilled instrument makers, woodworkers, &c., deals with the construction of experimental apparatus and the first models of instruments, &c., developed as the result of research. Development work is an important item in the station's activities, and from time to time many ingenious devices have been evolved for telephone and telegraph service. The main block of workshops consists of an assembly shop, coil-winding shop, instrument and machine shop, woodworkers' shop, and millwrights' shop housed in the single building behind the training school. At one end of the adjacent Durability Laboratory, two rooms are set aside for electroplating and paint spray work. A small job workshop equipped with vices and hand tools is also to be found in the main research building. The assembly shop is devoted to the assembly and wiring of apparatus, whilst the manufacture of special transformers and inductances is carried out in the coil-winding shop. The machine shop contains precision bench lathes, horizontal and vertical milling machines, a surface grinder, heavy lathes, a planing machine, a drilling machine, a power saw, gear cutter, and engraving machines. The woodworking shop is also well equipped.

Maintenance work associated with all the shops is carried out by the millwrights' department at the western end of the workshop building. This department is also responsible for heavy forging work and the manufacture of steel apparatus racks of special construction. The equipment includes a forge and a Massey 3 cwt. pneumatic hammer, oxy-acetylene blow-pipes for cutting and welding, and lathes, &c.

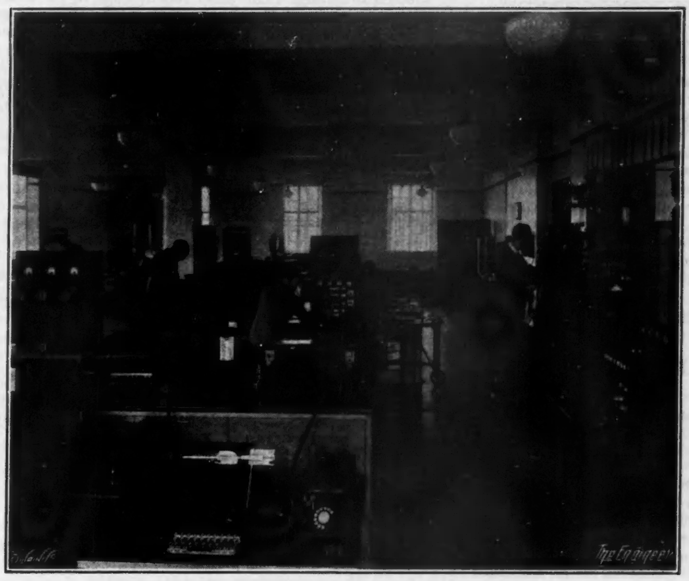

FIG. 3—TELEGRAPH LABORATORY

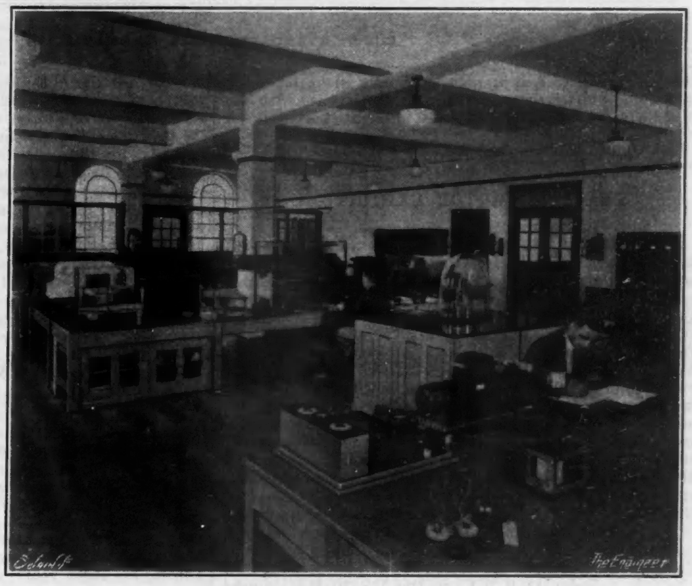

FIG. 4—PHYSICS LABORATORY

CONSTRUCTION PARK.

The construction park, covering an area of some 12,000 square feet, behind the workshop block, is partly used for research work in connection with overhead and underground constructions, and partly for the purpose of training men and youths in the handling of tools and appliances used on outside jobs. A standard pole route serves for training men in the erection of open wire, tree-cutting, staying, &c. Short poles have also been erected for practice in pole climbing, &c. Arrangements have been made for the poles to be armed near ground level, so that classes of men and youths may be given demonstrations of wire jointing, regulating, transposing, and the use of special tools.

Underground equipment, consisting of a multi-way duct route and cast iron pipes with manholes and jointing boxes of the usual type, is used for demonstrations in cabling and jointing operations. This duct route has also recently been used for research work in connection with the accumulation of gas in manholes and for work on cable sheath electrolysis. At one corner of the Park there is a bungalow with different types of internal walls which enable the fixing of apparatus on walls and partitions to be demonstrated.

SCOPE OF THE WORK.

Any attempt to describe all the work carried out at Dollis Hill in a few columns of THE ENGINEER must fall a long way short of actualities. The illustrations Figs. 2 to 4 give a general view of the main building, the telegraph laboratory, and the physical laboratory, while illustrations on page 408 show the chemical laboratory, the lines transmission laboratory, the signalling apparatus and circuits laboratory, and the teleprinter school respectively, but, as indicated in the foregoing description, there are many other departments. Microscopical and spectrographic laboratories are engaged, for instance, on the study of materials used in the construction and maintenance of telephone and telegraph apparatus. Instead of referring to all the laboratories individually, however, it will perhaps be better to endeavour in the remaining space available to mention very briefly some of the most important investigations that are at present being undertaken.

With a view to speeding up the methods of handling telephone calls in trunk circuits, new methods of signalling over telephone lines are being studied. Durability tests, which, in the course of a few months, subject intricate apparatus used in automatic telephone exchanges to wear equivalent to forty years or more of actual operation, under commercial conditions, are constantly carried out to ensure reliability. Investigations in connection with the transmission properties of telephone transmitters, receivers, and the associated circuits, involving voice and ear measurements, are carried out, for the most part, in rooms with various sound-absorbing wall and ceiling treatments, and with metal screens embedded in the walls to prevent electrical interference between one laboratory and another.

A master reference standard of telephone transmission provides a speech standard capable of absolute calibration with which commercial instruments may be compared. Similar reference standards exist in Paris and New York, and enable the standards of telephone transmission to be maintained on an international basis. The effect of all the factors likely to arise on commercial circuits, which are apt to impair the intelligibility of telephone conversations, such as room and line noise, are given attention. Means for rapidly testing the efficiency of the many hundreds of thousands of telephone instruments purchased by the Post Office have been developed, and new methods of measuring the transmission efficiency of subscribers' apparatus and lines are now available. A machine in one part of the station subjects the new types of telephone instrument to the usage it may be expected to receive in the hands of the public, in order to determine probable life and to show up any weak spots.

In the laboratories devoted to the testing of automatic telephone apparatus for durability, all kinds of equipment such as telephone dials, selector switches and relays, are continuously operated until failure occurs, or even to destruction, to enable the engineers to form an idea of how long the apparatus is likely to last.

Much of the research work on telephone lines is at present concentrated on carrier systems in which several separate channels for speech may be obtained on the same wires by the modulation of high-frequency carrier currents. It is well known that the development of such systems has enabled the carrying capacity of expensive submarine cables to be greatly increased, and has led to great economy in plant. In conjunction with this work, investigations are carried out in connection with repeaters used on long-distance telephone circuits.

Important work, as described in our issue of January 27th, 1933, is being done on the teleprinter. Ingenious methods have been devised for measuring the distortion of signals used to work the instrument and for repeating these signals so that the apparatus may be worked over very long lines. The Telex service by which any telephone subscriber may avail himself of teleprinter facilities was developed in these laboratories.

In the Cable Laboratory attention is given mainly to methods of measuring the electrical characteristics of cables and to investigations on methods of locating land and submarine cable faults. A new scheme recently devised has proved of great value in the way of enabling a fault in a submarine cable to be accurately located by means of apparatus connected to two electrodes towed in the sea by the cable ship. The method has been found considerably to reduce the period of delay due to the breakdown and to minimise the time the ship is engaged on the repairs. Problems which arise in connection with damage to telephone cables by corrosion, and those associated with the detection of gas in manholes, are dealt with in the chemical laboratory. For detecting gas a simple and inexpensive device has been devised for the use of men engaged on underground work. Tests to determine the effectiveness of protective coatings on telephone apparatus are in progress in this laboratory, the extreme conditions of climate and weather being simulated in spray chambers containing the specimens under examination.

In the acoustic laboratory tests are made on the acoustic performance of various speech-reproducing apparatus, and to provide the conditions necessary for accurate measurement a silence chamber has been built. Its walls are draped with a great thickness of sound absorbent material in order to prevent reflections of sound which would violate the results of measurements. As indicated in the plan, there is a radio laboratory which is devoted mainly to short and ultra-short wave work.

The total number of people employed or in training at the station often exceeds 600, and as there is no catering establishment capable of dealing with such a number within a mile of Dollis Hill, a large dining-room and kitchen have been provided for a financially self-supporting refreshment club. There is also a spacious lecture hall, which is used for a variety of purposes, such as conferences, and lectures to classes of men attending the station for training.

THE HIGH-SPEED OIL ENGINE.

THERE was a good attendance on Thursday evening last, at King's College, for the first of six lectures by Dr. S. J. Davies, M.I. Mech. E., on "Injection and Combustion in High-speed Oil Engines." The object of this series of special lectures, which will be held on consecutive Thursdays at 5.30 p.m., is to survey the present position of the high-speed oil engine, and to deal with certain sections of oil engine practice and operation which are not covered by existing knowledge of carburetter engines burning petrol or kerosene fuels.

In his introduction Dr. Davies dealt briefly with the history of the high-speed oil engine, which he characterised as a post-war development, largely bound up with the success obtained with the airless injection of fuel. Although this development owed much to Akroyd Stuart and other pioneers, the preliminary step was taken by Vickers in 1910, with the application of airless injection to submarine engines. Such engines, he pointed out, were primarily Diesel engines, and retained the same order of compression and maximum pressure after the charge.

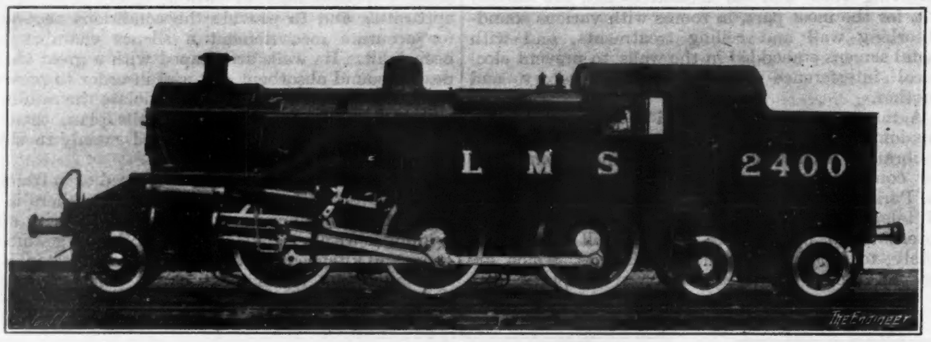
At the end of 1925 there were already in Germany six firms which had engines running at over 1000 r.p.m. and upwards in practical operation. In our own country excellent work was carried out at the Royal Aircraft Establishment, and by Beardmore's, and the presentation of Mr. A. E. L. Chorlton's paper before the Institution of Mechanical Engineers on March, 1926, and Mr. H. B. Taylor's paper before the Institution of Automobile Engineers on November, 1927, marked the beginning of intensive work on high-speed oil engines which has led up to the present satisfactory condition. To-day British-designed engines are produced for both road and rail service, and a wide and useful range of operating experience has been gained, and is available to possible users. Experience with Continental aircraft engines indicates, the lecturer stated, that the service time between overhauls can be materially increased beyond the largest possible to-day with the petrol engine.

THE Lithuanian Government has decided to place with a British company a contract for the installation of two automatic telephone exchanges at Kovno and Memel. It is understood that the contract is of the value of £170,000.

L.M.S. Tank Locomotive.

The accompanying illustration shows the new type of driving cab which is being fitted to the latest standard 2–6–4 tank locomotives (Nos. 2395–2424 inclusive), now in course of construction at the L.M.S. Railway Company's Derby locomotive works.

This cab embodies all-over roof, glass side windows, and a door with drop-light, and will afford increased protection for the driver and fireman, especially when the engine is running bunker first, as is frequently the case with this class, which is used largely for fast suburban services.



L.M.S. Standard 2-6-4, Tank Engine

THE FORD MOTOR EXHIBITION.

From October 12th until October 21st, there was held at the Royal Albert Hall the Ford Motor Exhibition, wherein were shown not only cars, trucks, and lorries, but also various industrial machinery relying for its motive power on Ford engines. The greater part of the floor space of the main hall was taken up with various road vehicles from the tiny 8 H.P. chassis to lorries and vans for all kinds of purposes. We noticed on the Fordson 131½in. truck that that form of springing had been adopted by which several leaves of each spring only come into action when the body is heavily laden, while on some of the smaller cars transverse springing, both at front and rear, had been fitted. In the industrial section, which was for the most part situated in the vestibule, the Ford 8 H.P. marine engine was to be seen. This engine weighs only 220 lb., has a length of 38in., a width of 13in., and a height of 22in., and will run up to speeds greater than 2000 r.p.m. That figure is, however, recommended as a limit. In the industrial field the various Ford productions, from the four-cylinder 14·9 H.P. to the V 8 30 H.P. engine, have been and are being used for a wide variety of purposes. Some typical applications were represented in the Exhibition. For agricultural purposes there was a Fordson tractor with a track measurement of 4ft. and a turning radius of 6ft. A "Planet" rail motor gang trolley, made by F. C. Hibberd and Co., Ltd., of Park Royal, and designed to carry six or seven men, has an 8 H.P. Ford engine. The "Lead Wool" type F C portable compressor set is equipped with the "B" model 24 H.P. engine, which drives another Ford engine with a specially designed head that is thus converted into a compressor. With a piston displacement of 115 cubic feet per minute, the compressor is suitable for pressures up to 100 lb. per square inch. The list could be extended almost indefinitely if all the applications were to be mentioned. Many of the machines using Ford power units have been described from time to time in these columns, and in the future many more no doubt will be so described.

SIXTY YEARS AGO.

A note, reprinted from *Lippincott's Magazine*, in our issue of October 31st, 1873, recalls an almost forgotten page in the history of steam navigation. We know that Fulton, during his visit to Europe, carried out experiments on the Seine on the propulsion of boats by steam, and that, returning to his native country, he constructed the "Clermont," and set her to work on the Hudson in 1807. If, however, the note to which we refer can be trusted, Fulton was only fifteen years of age when James Rumsey laid before Washington the model of a steam-propelled boat which he had conceived. Four years later, namely, in 1784, Rumsey launched his steamboat at Sir John's Run in the presence of Washington and a throng of visitors. Washington, it is stated, expressed the opinion that "the discovery is of vast importance, and may be of the greatest usefulness in our inland navigation." Rumsey adopted the principle which we now call hydraulic propulsion. He propelled his boat "by the reaction of a current squirted through the stern of the boat against the water of the river, the current being pumped by steam." This action was described by *Lippincott's Magazine* as "so primitive, so remote from the principle of the engine now used, that it seems hardly worthy to be connected with the great revolutionary invention of steam travel." Our contemporary was obviously unaware of the fact that Rankine had within the previous two years or so demonstrated the identity in principle of hydraulic propulsion with propulsion by paddle or screw. Rumsey, it would appear, was annoyed by one John Fitch, who, he alleged, frequented his workshop, carried off his ideas, and eventually in 1788 launched a steamboat of his own on the Delaware. It is recorded that Rumsey died in England of apoplexy at a public lecture at which he was explaining his system of propulsion. The story in certain of its aspects is circumstantial. Rumsey was stated to be a bath tender at Berkeley Springs. Berkeley Springs is in West Virginia, and Sir John's Run lies close at hand on the Potomac River. In 1780, the year in which Rumsey showed his model to Washington, the leader of the American forces moved down the Hudson, ostensibly threatening New York, but secretly changed his route, and hurried south through Philadelphia to attack Cornwallis at Yorktown. The surrender of that post, virtually ending the war, came in October, 1781. It is therefore clear that the celebrated general and the humble bath tender were at least within reach of one another in 1780. We can picture Washington listening to Rumsey, much in the same way as Napoleon some fifteen years later was to listen to Fulton while he explained his proposals for assisting the mechanical equipment of the army gathered for the projected attack on Great Britain. By 1784 peace had been made between this country and the revolted American Colonies, and Washington would be at liberty, so far as his military duties were concerned, to attend the launching ceremony on the Potomac. It may be added that Rumsey's contribution to the development of steam navigation—and also Fitch's—is to-day fully accepted by historians of the subject.

OBITUARY.

E. L. MANSERGH.

Civil engineers will deeply regret the loss of Ernest Lawson Mansergh, who died at Woking on Sunday last, October 22nd. Mr. Mansergh, who was born in 1866, was educated at Queenwood College, Hants, and the University College School, London. He began his career as an engineer immediately after leaving school, and was articled in 1884 to his father, the late James Mansergh, F.R.S. During his three years' pupilage he acted as an assistant engineer on the construction of the Hury reservoir of the Stockton and Middlesbrough Water Board. He then joined his father and was later made a partner in the firm of James Mansergh and Sons, which was constituted in 1902. Since the death of James Mansergh in 1905 he had been the senior partner of the firm, in partnership with his brother, Walter L. Mansergh, M. Inst. C.E. He was largely responsible for the design and supervision of the construction of many important works of water supply and sewerage, both in this country and abroad, among which may be mentioned the several reservoirs and the aqueduct in connection with the Elan Valley water supply for the City of Birmingham; the Blackton, Long Newton, and Grassholme reservoirs of the Tees Valley Water Board; the Font reservoir of the Tynemouth Corporation; the Castle Carrock reservoir and works in connection with the Geltsdale supply for the City of Carlisle. He was also consulting engineer to the Fylde Water Board in connection with the Stocks reservoir; the Langthwaite reservoir for the Lancaster Corporation, now in course of construction; and the sewerage and sewage disposal works for the municipality of Colombo, Ceylon. He was a member of the Institution of Civil Engineers and the Institution of Water Engineers, and a founder member of the Association of Consulting Engineers and its chairman for 1920 to 1921.

THE INSTITUTION OF GAS ENGINEERS.

The fifth autumn research meeting of the Institution of Gas Engineers will be held at the Institution of Mechanical Engineers, Storey's-gate, St. James's Park, S.W.1, on Tuesday and Wednesday, November 7th and 8th, 1933. The morning sessions will commence at 10 a.m. and the afternoons at 2.30 p.m. The following Reports will be presented and discussed:—

Fourth Report of the General Research Committee, 1932–33 (Communication No. 75).

Thirty-third Report of the Joint Research Committee of the Institution and Leeds University: Corrosion from Products of Combustion of Gas, Part I., Preliminary Investigations (Communication No. 76).

Third Report of the Liquor Effluents and Ammonia Sub-committee (Communication No. 77).

Twenty-fourth Report of the Refractory Materials Joint Sub-committee (Communication No. 78).

Second Report of the Gasholder Sub-committee (Communication No. 79).

Report on the Behaviour of Cokes in the Open Grate, contributed by Mr. H. J. Hodsman, Dr. E. I. Lloyd, and Mr. F. Bell, Leeds University (Communication No. 80).

Report on Leakage in Horizontal Gas Retorts, contributed by Mr. A. H. Clucas, City of Leeds Gas Department (Communication No. 81).

Tenth Report of the Gas Education Committee, 1932–33 (Communication No. 82).

THE NITRIDING PROCESS.

In a paper on Nitri-cast-iron, prepared by the Sheepbridge Stokes Centrifugal Casting Company, of Chesterfield, and presented at the Scottish Branch of the Institute of British Foundrymen on October 14th, it is stated that very frequently articles for case-hardening require some surfaces to be left soft for subsequent machining operations, the cutting of threads, keyways, &c. The protection of such surfaces from the hardening effect is commonly done by tinning. Pure tin or tin solder is generally used for this purpose. Although such solders melt at a lower temperature than the nitriding temperature, a sufficient amount will adhere by reason of surface tension, and will supply ample protection. In the application of tin, the parts are thoroughly cleaned and a flux of hydrochloric acid (killed) applied. The articles are then dipped into a bath of molten solder or tin and kept there sufficient time for the tin to adhere. The excess of tin can be shaken or brushed off with a wire brush on removal from the bath.

Nickel plating to a depth of 0·0005in. has been found effective in preventing the nitriding. Experiments have been made with protective paints. Positive results have been obtained with paints made up of stannous or stannic oxides. These compounds decompose in the nitriding furnace to form tin. Another protective paint consists of powdered aluminium and sodium silicate. This is applied with a brush to the surfaces to be protected and then allowed to dry. A hard coating is formed which can be removed after nitrarding by boiling the articles followed by scratch brushing. The most recent type of protective paint consists essentially of a mixture of finely powdered lead and tin suspended in an oily vehicle of animal oils. This can be applied to the articles by means of a brush or spray pistol. The fine coating of powdered lead and tin thus obtained on the surfaces melts at the nitriding temperature and thus exercises the same function as the solder applied in the manner previously described.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

STEEL RAILWAY SLEEPERS.

No. 500—1933. This is a specification for steel sleepers for flat bottom railway rails, and has been prepared by a committee representative of both the manufacturers and users.

The requirements of the specification and the sections standardised for the sleeper plates have been adopted after the most careful consideration of existing practice, both in this country and throughout the Empire. In so far as the design of the sleepers is concerned, the Committee has limited the specification to a series of standard sleeper plates from which the sleepers are to be pressed. Beyond this point the Committee did not consider it desirable to proceed, since a comprehensive review of present-day practice indicated that the variety of conditions under which the sleepers were used, and the diversity of opinion which existed in regard to the shape of the finished sleeper made it impracticable to prepare any standard requirements likely to meet with a reasonable measure of general acceptance. Similar considerations led the Committee to omit any requirements as to the method of fastening the rails to the sleepers.

The series of sleeper plates comprises ten basic sections, from 9½in. to 14in. in width. By opening or closing the rolls it is possible, however, to modify the thicknesses of the basic sections, thereby providing a total range of twenty-eight sizes in weights from 7½ lb. to 23 lb. per foot, a range which it is considered is adequate for all normal requirements and gauges. In the past quite fifty sections of sleeper plates have been in common use, which, though varying from each other to a small extent only, have necessitated separate rolls. It is believed that the reduction in the number of rolls will eventually lead to economy in manufacture.

The clauses of the specification detail requirements relating to the quality and physical properties of the steel, with particulars as to the manner of conducting the mechanical tests, the procedure to be followed in regard to inspection, both during and after manufacture, and requirements as to the coating composition and permissible deviation from standard weights.

The specification is primarily intended for sleepers for use with flat bottom rails, and it is for such use that the sleeper plates have been designed. Many of the requirements of the specification itself will, however, be found to be equally applicable for the manufacture of sleepers for bull-headed rails.

Plastics.—On November 8th, the London and Midland Section of the Institute of the Plastic Industry will visit Alfred Herbert, Ltd., Coventry, to see a demonstration of machines suitable for the production of moulds for plastic materials. The machines will be shown in operation on moulds and their parts. The demonstration will begin about 11 a.m., and luncheon will be served afterwards.

Institute of Fuel.—The seventh annual dinner of the Institute of Fuel was held on Wednesday, October 18th, at the Connaught Rooms, London, and attended by over 500 members and guests. In the absence through indisposition of the Minister of Transport, Lieut.-Colonel J. Colville, Secretary to the Department of Overseas Trade, proposed the toast of "The Institute." Beginning in lighter vein he later referred to the high value which the Government attached to the work of the Institute. The President, Sir William J. Larke, responded, and later presented to Sir John Cadman the Melchett Medal for research of an outstanding character involving the scientific preparation and development of the use of fuel. The speeches, which were all commendably short and of a high standard, were brought to a close when Mr. Loughnan St.L. Pendred replied to the toast of "The Visitors," proposed by Mr. R. D. Kitson. Members and guests then adjourned to the reception rooms for dancing. Later there was a highly enjoyable cabaret show.

Railway and Road Matters.

It is good news to hear that the London and North-Eastern has returned thirty-five locomotives to traffic from those that were withdrawn owing to want of business.

In order to make our record as to the Little Salkeld fatal accident of July 10th complete, we may say that in view of the porter-signalman's acquittal at the Carlisle Assizes on the charge of manslaughter, the coroner's jury on October 17th, returned a verdict of "Accidental death" in the case of the driver killed in that accident.

This month witnesses the diamond jubilee of the sleeping car on the West Coast route from Euston to Scotland, on which service the first car was introduced in October, 1873. The pioneer "sleeper" of sixty years ago was built at the London and North-Western Railway works at Wolverton, Bucks. It was only 33ft. long, compared with the 65ft. of the latest L.M.S. type.

During last year there was only one accident to a passenger train in which there was a loss of life. That was the derailment of Great Bridgeford in which four passengers were killed. There was also a collision between two empty carriage trains and the derailment of an engine. In the former a guard and in the latter a driver was killed. The record, up to now, of the present year is much less satisfactory, as there have been two fatal passenger train accidents, in one of which four passengers lost their lives, and another was killed in the second. There have also been four further accidents in which a total of eight servants have been killed.

At a meeting of the London County Council, held on Tuesday, October 24th, the proposal that Waterloo Bridge should be widened by corbelling out, in accordance with a design which has been prepared by Mr. G. Topham Forrest, the Architect to the Council, was approved. The design has been prepared in collaboration with Messrs. Rendel, Palmer and Tritton, of Westminster, the consulting engineers for the scheme, and has now been approved by the Royal Fine Arts Commission. Only the upper part of the bridge is to be widened, and the design shows that there will be the least possible alteration in the appearance of the bridge.

One of the many useful activities of the late Everard R. Calthrop, besides his great work on the Barsi Light Railway, was the building of the Leek and Manifold on the borders of Staffordshire and Derbyshire. That railway was subsequently taken over by the North Staffordshire, and so became part, later, of the London, Midland and Scottish system. Because it did not pay, the line was to be abandoned, but appeals from rambling societies, particularly those in Manchester, led to that proposal being withdrawn. Satisfaction is now expressed that the winter time-tables provide for a continuance of the train service, and the railway authorities have promised that if the line should be closed against traffic, the track should remain as a path.

If anyone who had occasion to spend some time in Carlisle Station in pre-grouping days, had a similar experience now, he might possibly be struck by the absence of the former variety in the types and colouring of the locomotives to be seen there. To-day there are only two companies using Carlisle Station—the London, Midland and Scottish and the London and North-Eastern. Just over ten years ago there were seven—the London and North-Western and Caledonian, who were the owning companies, and the Midland, North-Eastern, North British, Glasgow and South-Western, and the Maryport and Carlisle. Almost the same thing could be said of York. Formerly there were the North-Eastern, Great Northern, Midland, Lancashire and Yorkshire, and the Great Eastern; to-day only the L.N.E.R. and the L.M. and S.

According to the Railway Returns for 1932, one of the grouped companies—evidently the London, Midland and Scottish—has had its length of line remeasured, and the total figures, for all the railways, for the years 1927 to 1931, have had to be revised. The total length of road, for all British railways on December 31st, 1932, was 20,383 miles, a decrease of 12 miles. Expressed as single track, the total mileage of running line was 37,217 miles, an increase of 54 miles, and of sidings 15,683 miles, an increase of 47 miles. The length of new lines, widenings, &c., authorised for construction but not open for traffic, was 478 miles, of which 103 miles were for new lines and 375 miles for widenings. The mileage of track renewed was 1245½, as compared with 1359½ miles in 1931. The tonnage of the rails used was 201,444 as against 213,199 in 1931, and the number of sleepers was 3,910,793, as compared with 4,330,092.

The last occasion on which we referred to the railway traffic returns was on October 6th, when we dealt with those for the thirty-eighth week. On that occasion the receipts from passenger traffic showed useful increases, but less than those recorded in the summer. Whilst acknowledging that the abnormally fine weather has greatly contributed to this, the benefit mainly has come from the summer return tickets. We have, however, claimed that the increases those tickets have brought are more apparent than real, as, when a passenger takes a return ticket instead of a single, the company will be short of the companion single ticket for his return journey, besides getting only 2d. per mile for the double journey instead of two single trips at 1¼d. per mile each. It was obvious that as long as the holiday season was in being the loss on the single ticket for the return journey would be compensated for by other passengers taking the "summer" return, but as soon as the traffic slacked off the loss of the single ticket for the return would be noticed. That that is so is shown by the L.M.S. in the forty-first week being £9000 down; the G.W., L. and N.E., and Southern have increases of £6000, £5000, and £7000 respectively, as against £11,000, £13,000, and £14,000; and the L.M.S. a £13,000 increase a fortnight previously. In drawing attention to these facts we would say that we do so for fear it should be thought that there is a falling off in the passenger traffic; such, in our opinion, is not the case. There can, however, be no misapprehension over the goods traffic, as for the week in question the L.M.S. and L. and N.E. each had an increase of £33,000, the G.W. one of £14,000, and the Southern £2500.

Notes and Memoranda.

Some experiments carried out in America show that ozone is as effective in producing "knocking" in petrol engines as is lead tetra-ethyl in reducing it.

The official report on the explosion which occurred in the West Cannock coal mine, Staffs., on May 16th last, states that it was caused by an electric spark from a signal bell.

The new paper mill of the Blandin Paper Company in America has no windows, and both ventilation and light are provided artificially. The building measures 320ft. by 50ft., and houses a 156in. machine, which requires the circulation of 12,000 cubic feet of air at a temperature of 70 deg. to carry away the vapour produced in drying the paper. The latent heat of this vapour is recovered and used for heating the building.

Treatment of heavy oil engine cooling water in accordance with its chemical analysis before it enters the jackets is the best procedure, states Mr. L. O. Newton, who, at a meeting of the Diesel Engine Users Association, pointed out that though the addition of chemicals during circulation may prevent the deposition of hard scale, it turns the lime and salts contained in the water to soft sludge. This sludge must be removed; otherwise the passages will soon become choked.

Controversy as to the relative merits of cast iron and welded steel construction frequently overlooks the question of vibration, or its absorption, according to Mr. J. H. Godfrey, in the *Machinist*. According to experiments he has seen quoted, cast iron absorbs vibration twelve times better than steel plate and twenty times better than aluminium. The same tests indicated that the common variety of grey iron was better as a base for machinery in general, than the irons with alloys that gave them added strength. These alloy irons were not as good from the anti-vibration point of view.

A recent publication of the U.S. Geological Survey, concerning the Ashland coalfield in Montana, states that there are more than seventeen seams and an estimated resource of almost eleven billion tons of coal, most of it in five beds with local names, all in the Tongue River member of the Fort Union formation, which is an Eocene measure. All the coal occurs in about 875ft. of strata. Everywhere the outcrops are burned, forming a hard slag or porcellanite. Beds 20ft. to 25ft. thick occur, and persist at that thickness over areas of several square miles. Outcrops of coal beds 10ft. thick are common. No analyses of the coal are given.

The tensile properties and ductility of steel are not impaired by a tin content up to a maximum of 0·6 per cent., the yield point and the maximum stress being, in fact, slightly increased. On the other hand, if the amount of tin exceeds, at the most, 0·2 per cent., the impact value in the normalised condition is greatly reduced. In the heat-treated state this embrittlement to notched-bar tests occurs at still lower tin contents. The effect is much more detrimental if the steels are tempered at a low temperature after quenching, and if they are allowed to cool slowly through the temperature range from 400 deg. to 200 deg. Cent. after tempering. The ill-effect of tin upon the impact strength of these steels is minimised by quenching after a full tempering at about 620 deg. Cent. These effects bear a similarity to the "temper-brittleness" to be found in certain nickel-chrome steels. There is indirect evidence that the embrittlement may be due to thin films of carbide which are formed at the grain boundaries. If this be so, it may indicate that tin is a more objectionable constituent of high-carbon steels than of the lower-carbon material.

The Pennsylvania State College has been making experiments on the use of coal dust as a fertiliser in the growing of wheat, oats, and corn, and has come to the following conclusions:—The coal dust obtained from the Pittsburgh Coal Company contained no appreciable quantity of any important plant nutrient. It tended to increase soil acidity slightly and to decrease nitrification. Used as a surface dressing or mixed into the soil, it tended to lower the temperature of the soil and delay germination. When used as a surface covering ¼in. to ⅜in. deep it decreased evaporation materially, hence in dry years it might increase the yield materially, while in moist years it might have no effect. After it has been used as a surface dressing, ploughing and planting operations inevitably will incorporate it in the soil. As it has been shown that the product decreases nitrification and increases acidity, the cumulative effect of its use year after year might be expected to be injurious. It does not inhibit weed growth; therefore it would not be feasible for use on any cultivated crop, because cultivation would mix it with the soil and nullify any possible mulching tendencies. Its use in plant production appears undesirable.

Some tests carried out by the United States Bureau of Standards show that stoves for house heating should be spaced not less than 24in. from walls faced with wood, and the smoke pipes not less than 12in. below wood joists or ceilings. If bright sheet metal is applied to the walls, the spacing can be decreased to 12in. Similarly, plastered wood stud partitions, while requiring a spacing of not less than 18in. when unprotected, will be safe if only 9in. from stoves if the area exposed is covered with bright metal. Bright metal, such as galvanised iron, was found considerably more effective than black iron, since it reflects more of the radiant heat. Tests indicated that a ventilated air space of not less than 4in. all around the pipe, or of 2in. if filled with insulation, is necessary where smoke pipes pass through combustible partitions. If stoves are without ashpits, or if ashpits are heated to near redness, an air space of 5in. or more should be provided between the stove and a wood floor and the latter covered with incombustible insulation ¼in. thick under sheet metal. If the fire-box rests directly on the floor, the latter should be of incombustible materials throughout for the area surrounding the stove. For this condition temperatures high enough to cause ignition of wood were transmitted through a 4in. brick base. This explains the frequent occurrence of fires caused by ignition of wood forms left in place under brick or concrete arches supporting fire-places.

Miscellanea.

The Leipzig International Samples Fair will be held from March 4th to 10th, 1934.

A factory for the manufacture of paper-making machinery is to be put up adjacent to Hadfield's foundry in Sheffield.

The recently formed Copper Development Association has secured the services of Mr. Basil Marriott as its architectural adviser.

The estimated cost of the proposed cantilever bridge at Howrah is £1,500,000. It will have a 71ft. roadway, with tram lines and two 15ft. footways.

It is stated that by using oil instead of coal as fuel at its London headquarters, the National Institute for the Blind has saved £1231 during the past four years.

The turbo-blowers for the new Corby steel works, in Northamptonshire, of Stewarts and Lloyds, are to be made by Richardsons, Westgarth and Co., of West Hartlepool.

The twelve hollow-forged steam drums for the boilers necessitated by the re-engining of the liners "Alcantara" and "Asturia" are being made by Thos. Firth and John Brown, of Sheffield.

A brick-making works for using up oil shale refuse is to be put up at the Pumpherston Works, Mid-Calder. It is said that a process for the manufacture of a durable brick has been discovered.

The dismantling of the electric power station at Port Dundas, Glasgow, has been started. The station was erected in 1899, and with the completion of the grid system has become superfluous.

Public utility plants and plants operated in connection with manufacturing establishments and with mines and quarries in the United States have a combined rating in excess of 44,000,000 kW, and the total motor horse-power mounts up to a figure almost as large.

The Scotswood suspension bridge across the Tyne has been temporarily closed for the adjustment of the expansion plates at the ends of the span. Councillor J. Clydesdale says that the bridge, which is 100 years old, will have to be replaced within the next twenty years.

It is said that the steamer "Villa Selgas," which has been reported as foundered off the Spanish coast, is the original "John Bowes," the first iron screw collier, built eighty-one years ago at Palmer's Shipbuilding Yard, Jarrow-on-Tyne. The vessel was constantly in service.

On October 1st the first electric train was run between Stockholm and Malmö, electrification work on all sections of this important Government-owned line having been completed several months before the date fixed in the original programme. Next spring, when a new time-table comes into force, travellers will be able to do this distance in at least two hours less than by steam train.

At an informal meeting of the Junior Institution of Engineers on October 20th, Mr. A. C. Judd said that about eighty air-lift pumps were at work in the London area in which the lift was between 200ft. and 350ft., the quantity raised anything from 1000 to 20,000 gallons per hour, the bore-hole diameters varying from 6in. to 24in., and the depths usually between 500ft. to 700ft.

It is stated that the helio-station and the helio-laboratory of the All-Union Academy of Science, U.S.S.R., have elaborated a scheme for the mass production of solar apparatus. The design has been completed of a solar boiler of 5 square metres dimension, giving a million calories a year. Designs have also been made for a compound apparatus to work 200 days on solar energy and 165 days on fuel.

The work of the Sub-committee set up by the Institution of Electrical Engineers to inquire into electrical interference with broadcasting, indicates that devices for the suppression of interference from many items of electrical plant, particularly domestic appliances, could be incorporated in future designs at a reasonable cost. Further investigation is necessary on some of the larger items of plant, and tests of a quantitative nature are being carried out by the British Electrical and Allied Industries Research Association on such items.

In the course of the interim report of the Inter-Departmental Home-grown Timber Committee, recently issued, it is stated that the area classified as woodland in Great Britain is nearly 3,000,000 acres, of which some 300,000 acres are under State management, including 230,000 acres of young plantations made by the Forestry Commission since 1920. Approximately, 2,700,000 acres are private property. Fellings made during the war or immediately after accounted for about 450,000 acres, and included nearly all the best stands of ripe coniferous timber. Part of this area is still derelict. The remaining woodlands include a large extent of coppice and scrub, for which there is little demand.

According to the *Iron and Coal Trades' Review*, the Coltness Iron Company, Ltd., telephoned the Harland Engineering Company, Ltd., on Monday morning, inquiring for a pump set for urgent mine work. The set offered for the particular duty was the "MOB 6" pump, to deliver 200 gallons per minute against a 500ft. head, coupled to a 45 H.P., 500-volt motor, complete with a fabricated steel bed. Negotiations proceeded until 4.30 on the day mentioned, when definite instructions were given to the Harland Engineering Company to manufacture for delivery the following day. The drawing-office information was cleared in one hour, and this included drawing up a fabricated bedplate for the set. A stock motor was tested to determine its suitability for the work. The pump was built complete from its foundation, which process included the filing of impellers and guide ports to gauge as well as balancing the former; also the bedplate was manufactured, machined, drilled, and ready for assembly in time to match up with the completion of the pump. The set, complete with valves and gauges, was finished and ready for despatch by 2.30 p.m. on Tuesday, a total manufacturing time of twenty-two hours. It was then despatched to the client's colliery by motor lorry.

The Metallurgist.

THE OCTOBER NUMBER OF
THE METALLURGICAL SUPPLEMENT TO
"THE ENGINEER" ACCOMPANIES THIS ISSUE.

DEATH.

On October 24th, 1933, at 51, Crystal Palace Park Road, Sydenham, Henry Coke Powel, M. Inst. C.E., M.I. Mech. E., M. Soc. C.E. (France), in his 91st year.

EXCAVATION IN UNSTABLE GROUND.

Sir Henry Japp's paper descriptive of two new methods of carrying out excavation in "bad" ground, which was read before the British Section of the Société des Ingénieurs Civils de France at the Institution of Civil Engineers on Tuesday last, is an important contribution to engineering knowledge. We print the text of the first part of it on another page of this issue, and shall present the remainder next week. The difficulties with which engineers and contractors are confronted in excavating for deep foundations in unstable ground have at all times taxed their ingenuity. Necessity is the mother of invention. It is now more than one hundred years since the versatile Lord Cochrane patented the use of compressed air for shaft sinking and tunnelling in water-bearing strata. Little use was, however, made of the method until it was employed, about 1872, in constructing the foundation piers of the first Brooklyn Bridge, and it was not until 1879 that compressed air was used in tunnelling at Antwerp. In the same year compressed air was employed in driving the first tunnel under the river Hudson at New York and a little later came the first application of air to the building of quay wall foundations on a large scale. The diving bell, involving the employment of compressed air, as used in constructing the foundations of marine and other works, is, of course, of much greater antiquity than the air lock and its applications. In sinking deep shafts through alluvial ground the freezing process, first introduced about forty years ago, has often been employed, but more frequently abroad than in this country. It is a useful, although costly, method of sinking in situations where the amount of water expected to be met is too great to be dealt with by pumping and the pressures are too high to be balanced by compressed air. A few deep mine shafts have been sunk in this country by the freezing process and an outstanding example of such work, the sinking of two shafts in alluvial ground to form the intake and discharge openings for the condensing water tunnels of the Swansea super electric power station, has recently been described and illustrated in this journal.[*] One of these shafts was frozen to a depth of 172ft. below the coping of the walls of the King's Dock at Swansea. The freezing process has, however, as Sir Henry Japp points out, proved unsatisfactory when applied to tunnel driving, and compressed air working has hitherto afforded the most suitable means of overcoming the difficulties of tunnelling in quicksand. The limit of safe and economical working under pressure in tunnelling or shaft sinking is represented by a water head which does not greatly exceed 100ft. Some of the shafts sunk for the concrete core wall of the Silent Valley reservoir dam in the Mourne Mountains a few years ago were, however, successfully carried down to a depth of over 200ft. in water-bearing strata, the head of water in the surrounding saturated strata being reduced by pumping so that the air pressure within the working chamber seldom exceeded about 35 lb. per square inch above the atmosphere.

One of the two processes recently introduced to this country and described by Sir Henry Japp is likely to prove of great benefit to those responsible for dock construction where there is an underlying bed of dense water-bearing sand under high water pressure below the point of excavation. Until recently this condition has usually been met by the expensive process of sinking concrete monoliths by open dredging. The new method is the water lowering process, by means of which the water level in the strata is reduced by pumping in several tube wells of small diameter. Although we refer to this as a new process—having been introduced to this country only within the past two or three years—the system in one form or another has been employed abroad for nearly fifteen years. As now used in this country it was developed in Germany and in the United States of America, but it originated in the "step-wise" system of tube well pumping. The original method has been extensively employed in Germany, Holland, and Belgium in excavating the foundations for dry and wet docks in water-bearing sands. The later development, first employed in Germany in 1927, consists in sinking pipes from the ground surface to the full depth required and suspending in these pipes centrifugal pumps to discharge the water. The first application of the system in this country was in connection with the excavation of the dry dock for the Southern Railway Company, which was opened by H.M. the King in July last. We gave a brief account of the tube wells in our description of the dock works published at the time (July 14th, 1933) and a more detailed description will be found in Sir Henry's paper. At Southampton the pressure of artesian water in the bed of sand and pebbles, underlying at no great depth the clay in which the walls and invert of the dry dock are founded, represented a head of water of 94ft. at the underside of the invert of the dock. This would have resulted, if excavation had proceeded without lowering the artesian water, in such upward pressure on the layer of sandy clay under the invert as would have caused serious "blows." The only alternative would have been to construct a considerable part both of the walls and invert by the monolith system at a greatly enhanced expenditure. More recently the water lowering process has been used in the construction of the entrance lock at the new Grimsby Fish Dock, where water-bearing strata under artesian pressure lie immediately beneath the impervious clay in which the lock walls and floor are founded. The second process described by Sir Henry Japp is the chemical consolidation of water-bearing strata developed by Dr. Joosten in Germany during his management of certain potassium and salt mines at Nordhausen. He found that by impregnating the brine-charged ground in the mines with sodium silicate both the soil and the liquid were made into a hard mass by the chemical combination of the sodium silicate with the brine. Patents covering the application of the method to the solidification of loose soils were taken out in 1925 and 1926. The great advantage of this process is that it is possible to transform loose sandy gravel in a shaft or tunnel heading into a permanent solid layer impervious to water. The consolidation or petrification takes place at once, the sand and ballast being converted into a material resembling a sandstone or conglomerate. Small injection pipes are driven into the strata; a solution of sodium silicate is first pumped through the pipe, followed by an injection of calcium chloride solution, the pipe being withdrawn by short steps after each pair of injections. The system was first applied in this country in April, 1933, when John Mowlem and Co., Ltd., employed it on a trial length of the sewer diversion tunnel at the Bank-Monument Station of the Underground Electric Railways. Since then it has been used in England on several tunnel works, the underpinning of walls, and the consolidation of foundations.

Each of these processes is likely to be of great value in the carrying out of public works. The chemical consolidation process appears to possess certain advantages when compared with existing methods of forcing cement grout under pressure into the interstices of sand or gravel. For instance, in the cementation process the cement is likely to be segregated and left to set in hard globular lumps without reaching the fine interstices and accomplishing its intended purpose. The cost of the plant required for operating the chemical process is relatively insignificant, the principal expense being that of the chemical ingredients used. In this respect chemical consolidation seems to compare very favourably with consolidation by freezing, for which elaborate and expensive plant is required and which involves continuous and costly working of the freezing operations. Moreover, the chemical process seems to be capable of successful application in tunnelling operations where working under compressed air would otherwise be unavoidable, and Sir Henry gives examples of such conditions. One application of the chemical process, which seems to us to be obvious, is in the carrying out of deep foundation work and underpinning in water-bearing strata in proximity to buildings of outstanding importance where the abstraction of water from the underlying sands might result in movement of the foundations of the existing structures. We have in mind the conditions which obtain in the neighbourhood of St. Paul's Cathedral, the safety of which in connection with deep excavations in its immediate surroundings is a cause of constant anxiety to those responsible for the building. The advantages and economy of the water lowering process have been well proved in the case of the Southampton dry dock, and it is unlikely that such a work could have been constructed in the short space of two years had not Mr. Wentworth-Sheilds and the responsible contractors had the courage to take advantage of a system of working hitherto untried in this country.

Road Accidents.

Each year upon the roads of England, Scotland, and Wales there are killed as the result of accidents nearly 7000 persons. For every person killed about thirty are injured in some degree. Since the first records were taken, each year, with two or three exceptions, has shown a greater number killed or injured than that which preceded it. Little or no comfort is to be gained by reckoning the figures upon a vehicle-mileage basis, for although estimates prepared on such a plan are necessarily unreliable from the lack of important data, they suggest the existence of a figure constant at about three fatalities per 10 million vehicle miles. Though that figure may have a comforting sound to each individual driver, it means for the community at large a steady increase in the "toll of the road" in accordance with the increase in the number of vehicles in use from year to year. In 1930 the Road Act was passed, defining, among other matters, new road offences and bringing into action the mobile police. At the same time, the speed limit for private cars was abolished and raised to 30 m.p.h. for lorries and coaches. As a result of these reforms, it was hoped that an improvement in the accidents returns might be brought about. Yet, though fatalities have fallen from 7305 in 1930 to 6691 in 1931 and 6667 in 1932, it is questionable whether these figures represent a real improvement, or whether the reduction has been brought about by a lesser use of the road as a consequence of the depression. In London, alas! the returns for the quarter ended last September show a large and alarming increase over the corresponding figures for the preceding year in both deaths and injuries.

That the present position cannot be tolerated for any great length of time is conceded at once by every intelligent observer of road conditions, and many suggestions have been put forward as to how an improvement might be brought about. Road improvement is the great panacea of the road associations. It is claimed that development in the design of roads has failed to keep pace with the very rapid improvements in the vehicles which use them. Road surfaces should be light in colour to throw out in strong relief in the beams of the headlamps dark coloured objects, such as cyclists and pedestrians, and should have a high coefficient of friction even under the worst conditions of rain and snow. Super-elevation should be adopted at curves and unnecessary steepness of camber should be eliminated. Sharp, deceptive bends and blind or otherwise dangerous crossroads should be re-designed, and, where necessary, highly visible warning signs should be erected. In cities and urban areas it is suggested that pedestrian "traffic" might be regulated, and that improved forms of signal lamps will bring about improvements. Here, indeed, is scope for the engineer to make the roads as simple to travel upon as the machine he has devised is easy to drive and control. Supported by the road associations are various bodies, including the Government, that advocate education in road sense as a cure for accidents. The "Highway Code" is given to every applicant for a licence, and the mobile police constable is provided to admonish the delinquent and issue a summons against the reckless. Training in "road sense" becomes part of the syllabus of the school, and such bodies as the National "Safety First" Association carry on a valuable scheme of propaganda. Organised pedestrianism protests against excessive speeds, and points out effectively the difficulties and dangers of crossing roads in urban areas, and the peril involved by the lack of footpaths by the sides of main roads in the country. Lastly, the motorist points blandly at his neighbour as the miscreant who is the cause of all these accidents. Take steps, he suggests, to prohibit him from using the road, and all will be well.

---

[*] The Engineer, May 26th, 1933.

Unfortunately, except for the last of these remedies, none can have any immediate effect. The engineer can do much to improve the safety of the road, but his work will take years to complete. Education can only have any pronounced effect upon the next generation. As to the elimination of the reckless driver, the practical difficulties involved make any attempt to do so hazardous in its result, although the number of persons involved, it is to be hoped, is small. Nor is any present legislative action likely to bring about any immediate improvement, since it could only be founded upon insufficient evidence. How much is really known about accidents? The statistics collected by the police show their number and the type of vehicle to which each was attributed. But such figures give a quite incorrect impression unless allowance is made for mileage. No mention is made of the cause of the accident nor the place where it occurred. Were statistics collected of all the relevant details they might yield valuable information. In urban areas where do accidents most frequently occur? In the side roads, in congested streets, or in those more open thoroughfares where speeds are greater? Is the "accident rate" of roundabouts higher than that of crossroads? At what hour of the day do most accidents occur? What are the effects of differing climatic conditions on the figures? Are the majority of serious accidents attributable to a small minority of drivers? How many are caused by mechanical failures of some part of the vehicle? What percentage could have been avoided if more efficient brakes had been fitted? The correlation and tabulation of all the available statistics collected by road associations, borough councils, insurance companies, and the police is surely necessary before a true picture of the state of affairs may be painted. Statistics, however, are of little value until they have been collected for a number of years, whereas the cry is for immediate action. Such action would, we believe, be unwise. Let us have no "panic" legislation. Time has not yet been given for the provisions of the Road Act to take full effect, much less for those effects to be measurable. To reinstate the 20 m.p.h. speed limit, as has been suggested in some quarters, would be not merely a retrograde step, but, when cars are built to have a touring speed of 40 m.p.h., an illogical absurdity. Besides, in 1929, before the speed limit was abolished, there were more fatalities on the roads than in 1932!

Literature.

British Industries and their Organisation. By G. C. Allen, Ph.D., M.Com. London: Longmans, Green and Co. 1933. Price 10s. 6d.

Most books on economics make dull reading, and it is pleasant to welcome an exception. Even when the aspect selected is historical many authors fail to escape from the dreariness of the science. Not so Mr. Allen. He pursues an easy course through the Staple Trades, Coal, Iron and Steel, Engineering, Shipbuilding and Marine Engineering, the Motor Trade, and Textiles, and brings us in the end to a review of British industry since the war without once inclining the reader to say "Here, indeed, is a book for the shelves, where it may consort with others in the collection of dry dust; not one for the table where all and sundry may pick it up and find pleasant matters."

It is with chapters on our own subjects that we must concern ourselves—Iron and Steel, Engineering, Shipbuilding, and the Motor Trade. Sometimes, when one reads about the decline of Great Britain's share in the iron and steel trades of the world, he is led to believe that it is all the fault of the industry, something to be ashamed of, something that need not have happened had our ironmasters been more wide-awake. It is worth quoting Mr. Allen to correct this false impression. "This historical survey," he writes, "throws light on the essential instability of this industry. It shows that a position of apparently unchangeable supremacy may be undermined in a short space of time by technical changes which destroy the relative advantages of some producing areas and confer leadership on others. The discoveries of Darby and Cort transferred predominance in their industry from countries with large timber resources to England with her abundant coal supplies. The hot-blast, within a few years of its introduction, created a great Scottish iron trade. The inventions of Bessemer and Siemens destroyed the importance of South Staffordshire as a producing centre and brought about the migration of the industry to coastal areas. The Thomas process enabled the vast ore supplies of Lorraine, previously of little account, to be employed for steel-making, and so made Germany the chief European producer. When new methods of production are introduced an old-established producing area or country is necessarily at a disadvantage. The previous basis of its trade is destroyed, and it cannot expect to possess the same relative advantages for the new technique as for the old. Its plant is rendered obsolete and its *personnel*, bred to the old methods, has difficulty in adjusting itself to the new." Mr. Allen finds that the decline of the iron and steel industry lies in the fall in demand for products in which her competitive position was strongest, and he thinks it possible that its future lies with "specialities rather than with bulk products." There are many who hold that view, yet it may be that the whirligig of time will bring back the industry to this island where coal and ore lie cheek by jowl. Have we not already the signs at Corby?

We wish we could quote at length from this chapter, which shows a surprising knowledge of an industry in which the author is not engaged, and which surveys the position from the standpoint of sound common sense. Unlike so many others, Mr. Allen does not charge iron and steel masters with backwardness and idleness, but shows real sympathy with their difficulties and problems. After referring to the enormous world capacity of iron and steel plants since the war, he concludes with these words: "The future importance of great combinations in the iron and steel trade will depend on the extent to which this country remains a producer of the bulk products. If, as is not improbable, she devotes an ever-increasing proportion of her iron and steel capacity to the manufacture of specialities, then the small firm, like the small plant, may retain its importance." An interesting consideration which all those who think nothing can be good that is not great may ponder.

The short chapter on "Engineering" is not so good. It exhibits rather too much reliance on derived information and seems to lack the personal touch—as if the author had not endeavoured to draw his own conclusions from his premises. We pass over it; it only occupies eleven pages.

It is followed by a chapter on shipbuilding, which, apart from the fact that it shows some evidence of having been written a good many months ago, affords an interesting and useful survey of the development and position of that industry. The author contrasts the pre-eminence which Great Britain attained in steam shipbuilding with her primary backwardness in the introduction of the oil-engined ship. With regard to the former he writes: "She was a country with a diversified industrial life, and so could produce the multitude of components and materials required. She had cheap coal and a great share of the world's carrying trade, which expanded enormously after 1850. Free Trade gave her shipbuilders access to materials at low prices. Finally, the coming of the steamship coincided with a period of British supremacy in metallurgy and engineering, and the technique of these industries came to the aid of a shipbuilding industry of long standing and great experience." With regard to the marine oil engine he remarks that "It was not to be expected that the United Kingdom should achieve a position of equal superiority in the construction of these new types as in the old; for her great resources of steam coal rendered a change to ships using other fuels less urgent for her owners than for those of other countries." That is the philosophical attitude; it is better than recriminations. It takes into account forces which so many critics overlook or under-rate. It takes time to arrest the momentum of an old-established industry. It cannot be done in a day, and the greater and more successful the industry has been, the longer is the process. That this country has progressed so far with the internal combustion engine in a couple of decades is all to her credit, and yet it is natural that the old forces which made British steam marine engineering supreme should still be active. After all, coal is the proper fuel of this country, and its reinstatement—in some form—would bring immediate benefits to Great Britain.

Mr. Allen appears to be not quite happy about recent movements in the shipbuilding industry. Of the Rebate Scheme he says: "Unfortunately, it is impossible to determine how far the operation of this scheme has maintained the cost of construction above the level which might otherwise have been reached. But it is significant that this great exporting industry now has to purchase the bulk of its materials from trades dominated by combinations and price-fixing associations"; and on another page he writes: "Yet as the yards still in existence are capable of producing 2½ million tons, while the maximum annual output of merchant vessels since 1921 has amounted to only 1,520,000 tons, it seems that the National Shipbuilders Security is still far from realising its aims." Yet in the last words of the chapter he admits that "the structure of one of the most individualistic of the British trades has at length been modified."

We skip a couple of chapters in order to conserve a little space for Chapter X., in which "British Industry Since the War" is reviewed. Here, as in some earlier pages, we observe omissions which are difficult to explain save on the assumption that the text was written many months ago. The most remarkable recent event in the industries of the country was the re-establishment of import duties, yet home tariffs are not discussed in any part of the book and are not mentioned even in this chapter. Since we can hardly assume that the author regards protection as an influence without moment in the development of industries, we suggest that the volume should bear the date 1930 or 1931 rather than 1933.

After the presentation of certain data and statistics, Mr. Allen asks two questions: "First, how is the change in the relative importance of the different industries—a world-wide phenomenon—to be explained; and secondly, why did Great Britain, of all the industrial nations, suffer the most severe losses in the older trades while failing to secure a compensating share of the growing industries?" It would take more space than we can spare to follow his argument, and we can do no more than mention his conclusion that the failure of Great Britain to maintain her place in international trade was due in large measure "to the displacement, as a result of changes in demand, of trades and qualities of goods in which she had specialised, and to the necessity for exceptionally great readjustments imposed on her industrial system by the circumstances of the post-war world." The chapter ends with the following passage, with which we must leave a book in the reading of which we have found much pleasure: "In any case, it is now generally recognised that Great Britain cannot expect her older staple industries to regain their previous importance in her economic life. The solution of her problems must ultimately come from a redistribution of labour among other trades. But it is by no means easy to discern what those trades are to be. Nor is it possible to state with confidence that in the future the advantages of Great Britain as an industrial centre will be sufficient to enable her to maintain a dense population at the standard of life to which she has been accustomed."

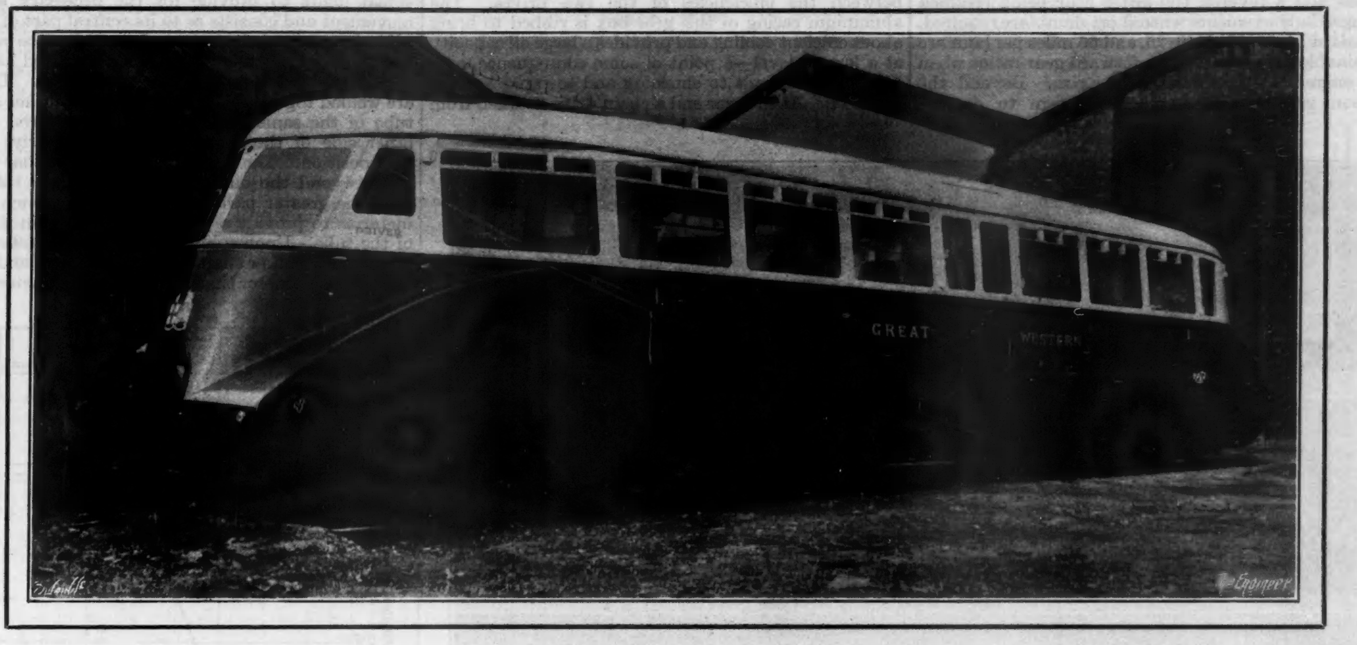
130 H.P. RAILCAR FOR GREAT WESTERN RAILWAY

HARDY MOTORS, LTD., SOUTHALL, MIDDLESEX, ENGINEERS



130 H.P. Oil Engine-Driven Railcar.

At the end of last July we were able to give a short illustrated description of the chassis of an oil engine-driven railcar manufactured by Hardy Motors, Ltd., of Southall, and fitted with a 130 H.P. A.E.C. oil engine. At that date the vehicle was still more or less in the experimental stage, and some of the smaller details of its design were not definitely settled. Nor were the makers ready to publish details of the body which was to be fitted to it. The experimental running of the chassis has now been satisfactorily completed, and as may be inferred from the engraving at the head of this page, the body has been fitted. The complete vehicle, which will be shown at the Commercial Motor Transport Exhibition opening at Olympia next Thursday, has been purchased by the Great Western Railway Company, and will enter service, probably between Slough and Reading, at the close of the Exhibition.

The coach, as will be observed from the engraving above and the drawing, Fig. 1, is of a stream-lined form. It was made and fitted to the chassis by Park Royal Coachworks, Ltd., of Abbey-road, Park Royal, N.W.10. The reduction of windage resistance and judicious saving of weight in the design of the chassis has made it possible for the 130 H.P. engine to give the vehicle a satisfactory performance. Carried on two four-wheeled bogies, the car is 62ft. long by 9ft. wide overall, and weighs less than 20 tons. The power-weight ratio is therefore higher than it is on most railway trains or vehicles. Besides a luggage compartment at one end, the coach has accommodation for sixty-nine passengers, but we understand that as many as eighty-eight could be carried if the luggage compartment was not present and the seating rearranged. The important influence of the smoothness of the exterior of the body on the windage resistance has been fully realised, and there are practically no external projections whatever. Even the steps to the driver's cab from rail level have been arranged to be covered by flaps when the door above them is closed, and hinges which must project are of stream-line form. The coach is painted in G.W.R. colours. It was designed to follow out the results of wind tunnel tests on a number of models, some of which are illustrated in Fig. 2. A graph—Fig. 4—the curves upon which are lettered to correspond with the model photographs in Fig. 2, shows the wind resistance in pounds of the models plotted against speed of motion. The curves have been extended beyond the results of the actual wind tunnel tests themselves, as shown by the dotted lines, in order to judge of the performance of the vehicles at higher speeds. Curve F, which shows a very high resistance, applies to a coach with flat ends of conventional form, except for the shrouding of the wheels. It was taken in order that some basis for the comparison of the stream-lined vehicles might exist. The best results were achieved by the model A, but, as we think our readers will agree, a vehicle constructed to have the shape of this model would be frankly ugly. A design which would give comparable results and at the same time have a pleasing form was therefore sought, and models B and C were the result. At first glance, these two might be taken to be identical, and, in fact, the only difference occurs in the shape of the roof, which in B is curved upwards at the centre 6in. relatively to C. The surprisingly large influence of this small change of shape may be traced upon the graph. As might be inferred from the engraving at the head of this article, it was decided to construct the body in accordance with the shape of model B. The other curves on the graph refer to models of other forms examined by the makers, but since they had no influence on the final design adopted, they need no further reference here.

The Chassis.

The design of the chassis of this railcar is unusual in that the engine is placed within the body and to one side of the frame near the middle of its length. Regarding, for purposes of description, the driving bogie end as the rear end of the double-ended coach, the engine is situated on the left-hand side of the frame a little forward of the central position. The arrangement will be made clear by a reference to the drawings reproduced in a Supplement to this issue, and by the photograph reproduced in Fig. 3. Both axles of the rear bogie are driven and the whole transmission system lies outside the main frame on the left-hand side of the vehicle. The mechanism is, however, hidden from view in the completed coach by the shrouding which extends to within a few inches of the rails. As far as possible, consistent with the best modern practice in railway carriage construction, weight has been saved in the main frame and bogies, so that the total weight of the chassis is only 13 tons 10 cwt. The general design may be followed from the drawings reproduced in the Supplement. Before a choice was made consideration was given to the advantages of several different types of bogies and a design was finally decided upon that could readily be adapted to suit both the braking and driving systems it was intended to employ. As will be seen from the drawings, each bogie is of the swing link bolster type, with laminated springs over the axle-boxes and an auxiliary rubber suspension block; and nests of coil springs between the bolster and spring plank. The main frame allows the engine and the various units of the transmission system to be conveniently carried by outrigger members cantilevered from it. An additional advantage of the construction is that convenient steps from rail level into the body of the car at the central vestibule can be built in without the necessity for any projection that might increase the air resistance of the vehicle. A "trap door" in the floor may be raised and steps have been built in below the floor and clear of the frame to rail level. A panel on the body opposite the steps is hinged and so connected with the "trap door" that it opens outwards as the flap is raised. The main members of the frame are 10in. by 3½in. channels trussed with 4in. by 4in. by ½in. angles.

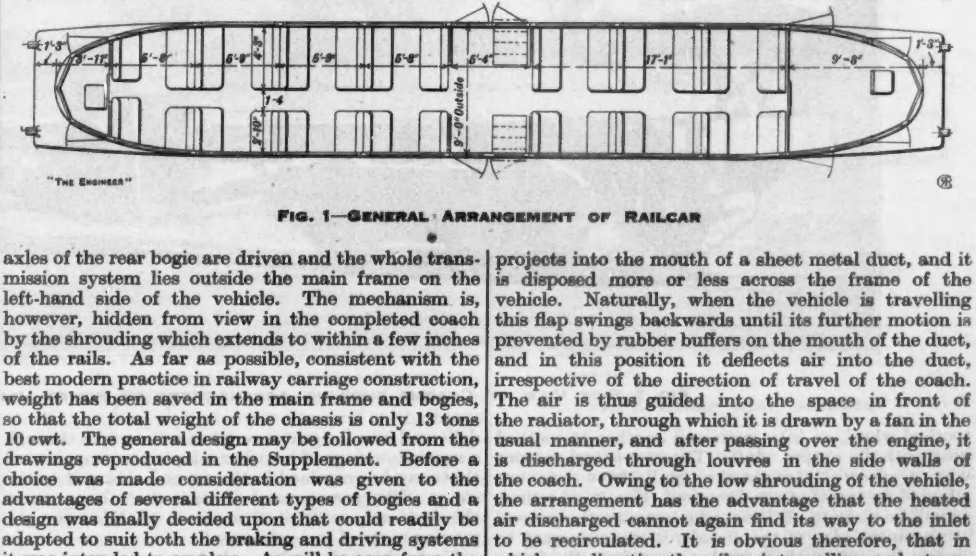


Fig. 1—General Arrangement of Railcar

Engine and Transmission.

As a result of careful stream-lining of the body and judicious saving of weight in the chassis, the 130 H.P. A.E.C. oil engine, similar to that fitted in many commercial road vehicles, provides ample power. The radiator for the engine is mounted conventionally in front of it. Since, however, the whole engine unit is enclosed within the bodywork of the coach, special measures had to be taken to cause a flow of air through the radiator. Beneath the car there is a swinging sheet metal flap hung on a vertical axis. Its free end projects into the mouth of a sheet metal duct, and it is disposed more or less across the frame of the vehicle. Naturally, when the vehicle is travelling this flap swings backwards until its further motion is prevented by rubber buffers on the mouth of the duct, and in this position it deflects air into the duct, irrespective of the direction of travel of the coach. The air is thus guided into the space in front of the radiator, through which it is drawn by a fan in the usual manner, and after passing over the engine, it is discharged through louvres in the side walls of the coach. Owing to the low shrouding of the vehicle, the arrangement has the advantage that the heated air discharged cannot again find its way to the inlet to be recirculated. It is obvious therefore, that in whichever direction the railcar is travelling, a plenteous supply of cool air will be drawn through the radiator.

Immediately behind the engine there is a fluid flywheel, which takes the place of a clutch. Thence a shaft with two universal joints takes the drive to the pre-selective gear-box of the Wilson type. It is at this point that descent from the interior of the coach to rail level is made, and the shaft is so placed that it does not interfere with the construction of the steps mentioned above. The gear-box gives four forward speeds and a reverse, the latter gear being retained owing to its convenience when short shunts are required. Speeds of 14·45, 25·4, 40·25, and 60 miles per hour are obtainable by the use of the forward gear ratios when the engine is turning at 2260 r.p.m. Beyond the Wilson gear-box the next mechanism to deserve notice is the reverse gear-box, a section through which is reproduced in the Supplement. In whatever direction the vehicle is travelling there is no conventional direct drive, as a study of the engraving will demonstrate at once. The output shaft is situated below and further from the main frame of the vehicle than the input shaft and connected with it by constant mesh gears. A dog clutch engages the input shaft, upon which it rides, through two 43-toothed intermeshing gears, or alternatively through a 35-toothed wheel, an idler gear, and another 35-toothed gear, with the output shaft. There were two reasons why a direct "straight-through" drive was not adopted for travel in one direction. Firstly, of course, as will be clear to all those who examine the general arrangement plan of the chassis, it was necessary to situate the output shaft further away from the frame than the input shaft in order to take the drive to the axles in the manner shown. But of far greater influence was the fact that, given a "straight-through" drive in one direction, no less a number of gear wheels than five is necessary to obtain reverse. An arrangement by which two gear wheels were engaged for the drive in one direction and three for the drive in the other involved no greater number of gear wheels and made no such great distinction between the efficiencies of the two drives. The aluminium casing of this gear-box is ribbed to bring about efficient cooling and provides a large oil capacity at a low oil level—a point of some consequence, as a high oil level leads to churning and to rapid heating of the oil. At the rear end a chain drive is taken from the output shaft to a rolling drum exhauster mounted on the top of the gear-box. This exhauster maintains the vacuum in the reservoirs of the brake system and is additional to another exhauster driven directly by the engine. It is provided to maintain the vacuum when, for instance, the vehicle is coasting down a long hill with the gears of the "Wilson" box in neutral and the engine idling, under which conditions the engine-driven exhauster is more or less out of action owing to its low speed. The exhausted air is delivered into the gear-box, whence it escapes through a specially designed breather adapted to trap any oil that may be entrained in the air and return it to the sump. The arrangement is such that the gears in the box act as "oil throwers" to lubricate the moving parts of the exhauster.

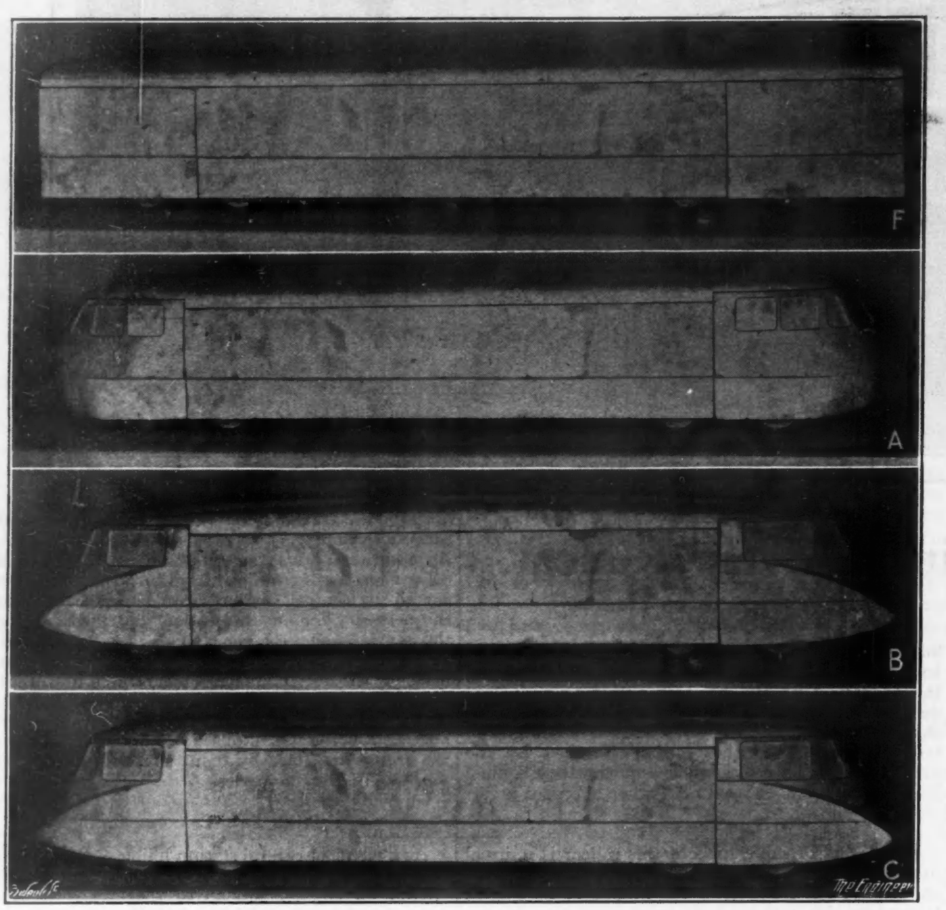

Fig. 2—Models for Use in Wind Tunnel Tests

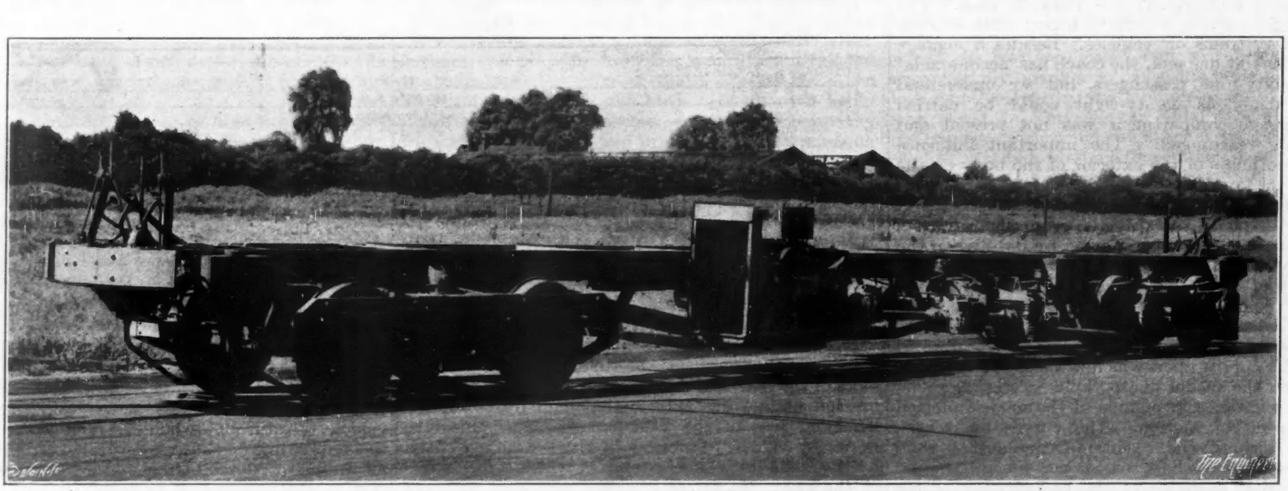

Fig. 3—Side View of Chassis showing Arrangement of Power Unit and Transmission

Up to this point it has only been necessary to provide universal joints in the connecting shafts between the units of the transmission system to allow for differences of angularity. In the connection between the reverse gear-box and the driving axles, however, a further degree of flexibility is necessary in order to allow for rotation of the bogie round its centre pivot. The design of the telescopic shaft forming this link in the system may be seen in the drawing Fig. 5. It is carried between two universal joints to provide for the necessary angular movement and consists as to its central part of a tube 3½in. in external diameter. Into this tube at each end there is fitted the "butt" of a solid rod having a shoulder of the same diameter as the tube. The two are welded together at the shoulder. Another shorter tube of the same diameter fits over the rod on the other side of the shoulder and is similarly welded into position. The rod is of such length that it projects beyond the outer end of the second tube and over the greater part of its length is of such a diameter as to provide a wide clearance within the bore of the tube. Upon splines cut on the projecting part of the rod a hollow shaft is adapted to slide, and, being of smaller diameter than the internal diameter of the tube, its end can project into the clearance space between the rod and the tube. The outer ends of these two hollow shafts connect with the universal joints at each end of the telescopic shaft assembly. As will be seen from the drawing, covers screwed on to the ends of the tubes and nuts screwed on to the ends of the shafts prevent the complete withdrawal of the shafts from within the tubes, but dismantling of the assembly is easily performed by the removal of the caps, which are held in position by locknuts and contain a sealing ring to prevent leakage of the lubricant. A motion of 4½in. is provided at each end of the assembly and lubrication is obtained by filling the clearance spaces with grease.

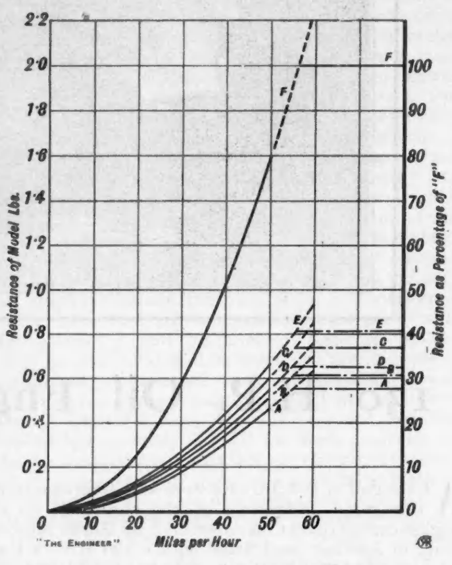

Fig. 4—Results of Tests of Models in Wind Tunnel

The next mechanism to be described is particularly interesting, and the true merits of the design cannot be appreciated without considerable study of the drawing reproduced in the Supplement. Both axles of the rear bogie are driven—see also Fig. 6—through worm and wheel mechanisms, and as any difference in the diameters of the wheels would set up undesirable stresses in the shaft between the two worms an inter-axle differential gear is housed in the casing of the leading axle-box. The drawing reproduced in the Supplement refers to this leading axle. In general, the design of the worm drive to the other axle is the same except for such differences as the omission of the differential brings about. The main feature of the design, which is covered by patents, is the manner in which the worm is carried in the axle-box casing.

From the flange which is attached to the universal joint of the telescopic shaft the drive is taken to the central member of the differential gear. One of the outer members of the differential passes on the drive to the second axle, while the other is solid with the worm driving the first axle. The neat manner in which the various parts are firmly supported is better discovered by examination of the drawing than it can be described here. The worm wheel is bolted and splined to a flange carried on the axle itself, and the manner in which its mesh with the worm is adjusted deserves mention. It will be observed that there are two end covers for the worm wheel assembly, the smaller bolting into the larger. A ball thrust and journal bearing is carried by the smaller of these two covers. Since the large roller bearings that transfer the load of the vehicle on to the axle are so designed as to have no locating properties, it is this ball bearing that locates the casing relatively to the axle. Thus by placing shims between the smaller cover and the face to which it bolts the position of the axle relative to the axle-box—or, in other words, the position of the worm wheel relative to the worm—may be altered. Another important feature of the whole design becomes apparent after a little study of the drawing. The whole of the worm and wheel mechanism may be dismantled for repair, replacement, or examination without even relieving the axle of the weight of the vehicle. Removal of the larger cover allows the worm wheel to be withdrawn, while the worm assembly is easily removed when the end covers of its casing have been taken away. Moreover, all these covers are situated accessibly at the side of and not beneath the vehicle.

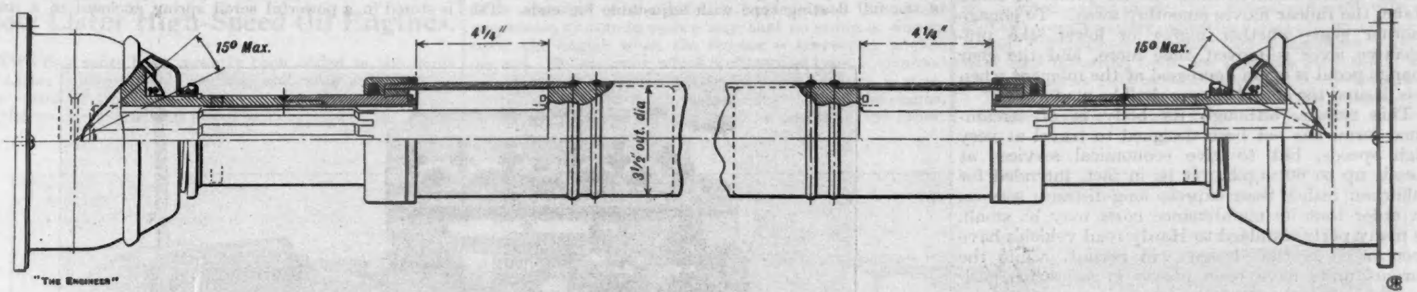

FIG. 5—THE TELESCOPIC SHAFT BETWEEN REVERSE GEAR-BOX AND FINAL DRIVE

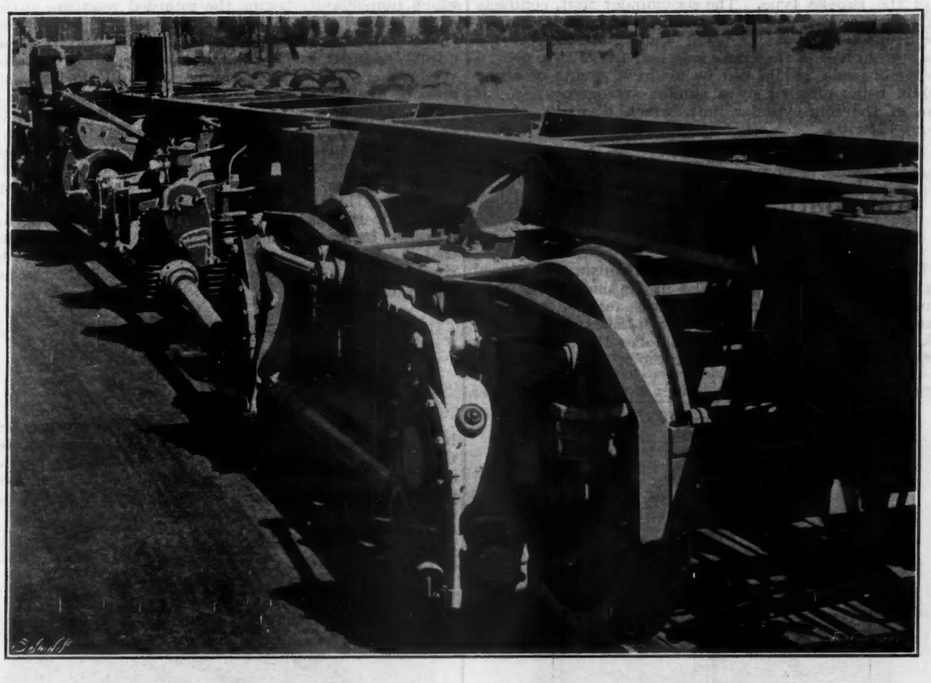

FIG. 6—THE DRIVING BOGIE

As we have already noted, the axle rotates in roller bearings within the axle-box. An arm projecting from the top of this box is attached by a ball-ended lever to the end of a torque rod. The springs, therefore, which are clamped to the axle-box sleeve take none of the torque. A small detail indicative of the care and thought which has been put into the design of the railcar is illustrated by the accompanying sketch, Fig. 7. Here the large circle indicates the wheel. The axle-box and its guides, together with the torque rod, are also shown diagrammatically. Supposing the vehicle to be travelling towards the right, the torque reaction will be anti-clockwise and the torque rod, attached above the axle, in tension. Thus the force in the torque rod tends to pull the axle-box against just that set of guides on which the pressure to drive the vehicle along is being exerted. Were the torque rod to be connected below the axle, as indicated by the dotted lines, its effect would be in opposition to the driving pressure, and the arrangement might well give rise to chatter at the driving face of the guides. The axle-box itself is also mounted in a sleeve so that the thrust on the guides may be truly normal. Otherwise one of the effects of torque reaction would be to give the box a tendency to cant in the guides and bear only on the corners.

BRAKE GEAR.

In the brake gear a departure has been made from conventional railway practice by the fitting of internal expanding brakes similar to those of a road vehicle. Between road and rail vehicles, however, there is the essential difference as far as brake gear is concerned that in the one case the wheel may be readily removed, while in the other it may not. The mechanism is so arranged on this railcar that access can be gained to the shoes, operating cams, and pivot pins without removing the drums or wheels. The whole assembly, a drawing of which is reproduced in Fig. 8, is mounted on the axle behind the wheel. The drums themselves, split to be removable for truing up or replacement, are bolted and registered into the wheels, while the rest of the gear is mounted on a carrier riding on roller bearings on the axle and prevented from rotating by a torque rod. A split collar clamped to the axle retains the carrier in the correct position and holds it up against the face of the wheel. It will be clear from this description that it is only necessary to slack back the retaining collar, detach one end of the torque rod and disconnect the brake rod in order that the whole carrier may be slid back along the axle and the various parts mounted upon it inspected.

Two vacuum cylinders are mounted on each bogie. Each is independently connected to the brake cam shaft lever of one axle, so that complete compensation of the brakes is ensured. A cross-shaft of compensating type coupled to the hand brake lever in the driver's compartment is also connected to the brake cam levers. Vacuum for the brakes—and also incidentally for the sanding gear—is maintained by two exhausters, both of which have already been mentioned. Three reservoirs are mounted beneath the chassis, and gauges in the driver's compartments show the vacua in these reservoirs and in the brake pipe.

Before passing on to describe the controls, it should be noted that a large-capacity electric accumulator battery is mounted on the frame just opposite to the engine, while the fuel tank is on the same side as the accumulator, but further back.

CONTROLS.

The controls under the charge of the driver are arranged in an identical manner at each end of the vehicle. They comprise an accelerator pedal, a preselective gear lever, a reverse gear lever, a ratchet hand brake, a finger-control lever for the vacuum brake, and another for the sanding gear. Lastly, there is a pedal for changing gear in the Wilson box, for it will be recalled that in this type of box the next gear to be engaged is pre-selected, but not actually engaged until a second control is operated. The hand brake lever at each end of the coach only applies the brake on the wheels of the bogie immediately beneath it. The two levers are thus not interconnected. In the case of the reverse gear lever and the preselective gear lever, however, interconnection is necessary. It is obtained by means of steel ribbons attached to the ends of double-ended levers mounted beneath the coach and rotated by the controls. The arrangement is such that whatever the direction of rotation one of the ribbons is in tension. Approximately half-way along the vehicle a double-ended lever is mounted between the two ribbons and to it is attached a rod making connection with the mechanism controlled. A similar arrangement has been adopted for interconnecting the gear change pedals at each end of the car with the Wilson gear-box. As, however, the "working" movement is always in the same direction and a spring can be arranged to give the return motion, only one steel ribbon is required, and it is always in tension.

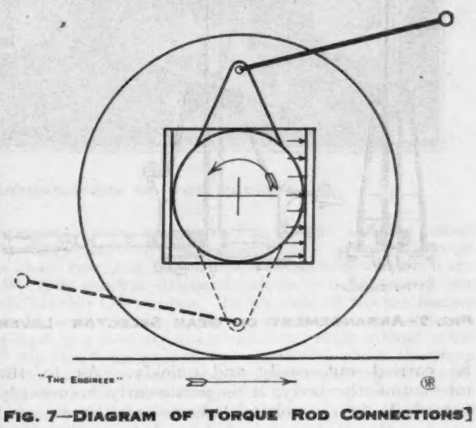

FIG. 7—DIAGRAM OF TORQUE ROD CONNECTIONS

As the gear-selecting lever works in a "gate" trouble might arise through the gate at one end of the vehicle interfering with the free motion of the lever at the other. To make any such state of affairs impossible, only one gear-selector lever is supplied. It is so arranged—see Fig. 9—that it may be lifted out of its socket and, when the direction of motion of the car is reversed, carried from one end of the coach to the other. It is the toe of this detachable lever that engages with the gate, so that when it is removed no interference is possible. There are only four slots in the gate corresponding to the four

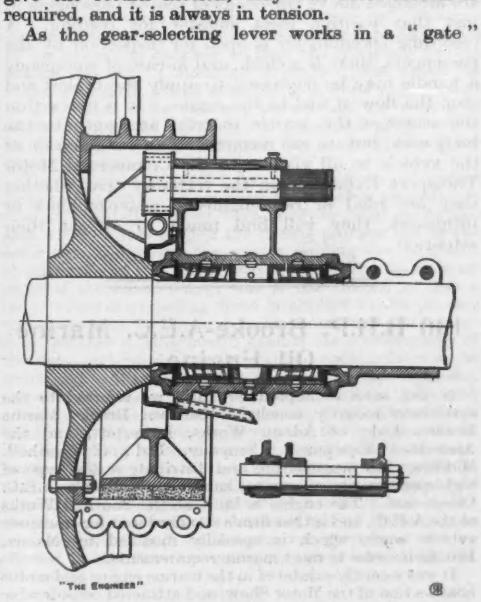

FIG. 8—BRAKE GEAR ASSEMBLY

forward ratios available. Reverse is obtained by lifting the lever slightly to clear the gate and drawing it back as far as it will go.

The coach is very simple to drive. An electric starter brings the engine into action. The reverse lever is next thrust in the direction in which it is desired to travel, and the pre-selective gear lever is brought through the gate to the " first " or " second " gear position. Then, on pressing down the gear change pedal and releasing the air brake or hand brake, the railcar moves smoothly away. To engage another gear—whether higher or lower—the pre-selective lever is moved once more, and the gear change pedal is again depressed at the moment when it is desired the actual change shall be made.

This railcar, although its body is of stream-lined form, has not been designed to travel at very high speeds, but to give economical services at speeds up to 60 m.p.h. It is, in fact, intended for suburban rather than express long-distance service. In order that its maintenance costs may be small, as many parts standard to Hardy road vehicles have been used as the design will permit, while the various units have been placed in accessible positions so that the replacement of worn parts may be carried out easily and quickly. As to the interior of the body, it is particularly luxuriously furnished in a colour scheme of brown and green; the seats are upholstered in leather, and the passengers sit back to back. At one end a door leads into the luggage compartment, but at the other glass panels are interposed between the driver and the interior of the coach. As long windows are arranged on each side, the coach has a visibility as good as that of an " inspection " car. Deep luggage racks are provided and lights mounted beneath them are arranged above the heads of seated passengers in just that position most suitable for reading. A recording speedometer is open for inspection by the passengers, there is a clock, and in case of emergency a handle may be depressed to apply the brakes and stop the flow of fuel to the engine. It is not within the scope of this article to refer at length to the bodywork, but we can recommend an examination of the vehicle to all visitors to the Commercial Motor Transport Exhibition in the certainty that whether they are road or rail engineers, coachbuilders or furnishers, they will find much to attract their attention.

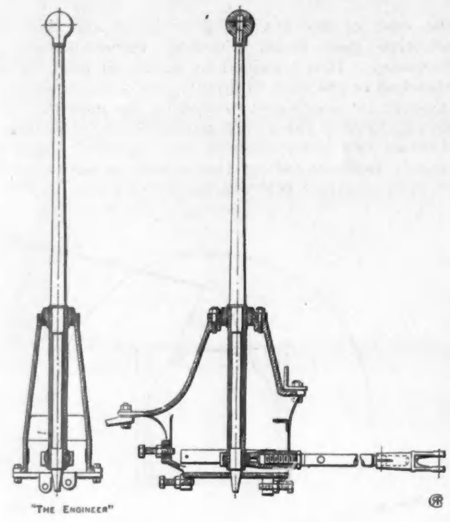

Fig. 9—Arrangement of Gear Selector Lever

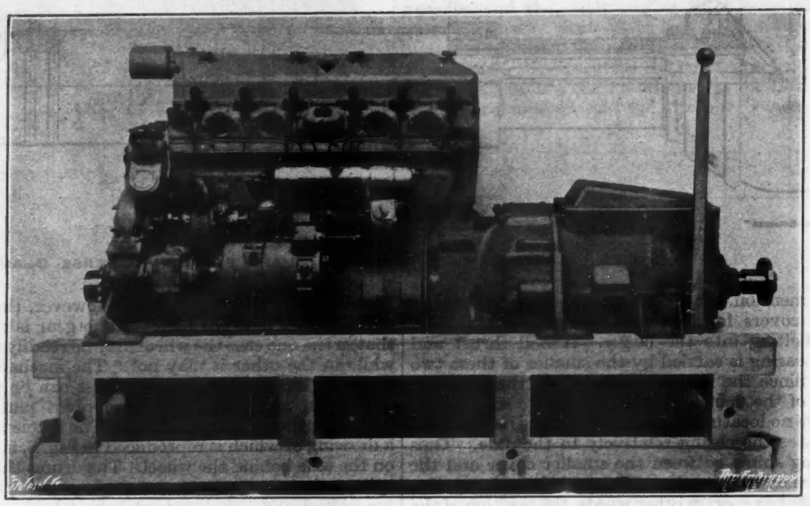
130 B.H.P. Brooke-A.E.C. Marine Oil Engine.

In our issue of September 15th, we referred to the agreement recently concluded between Brooke Marine Motors, Ltd., of Adrian Works, Lowestoft, and the Associated Equipment Company, Ltd., of Southall, Middlesex, to manufacture and distribute a new type of high-speed marine oil engine, known as the Brooke-A.E.C. Diesel unit. The engine is built at the Southall Works of the A.E.C., and is that firm's standard unit for transport vehicle work, which is specially modified by Messrs. Brooke in order to meet marine requirements.

It was recently exhibited in the marine engine and motor boat section of the Motor Show, and attracted considerable attention. Two models are included in the new range—a four-cylinder unit, with a bore of 108 mm. and a stroke of 146 mm., designed to develop 40 to 70 B.H.P., and a six-cylinder unit, with a bore of 115 mm. and a stroke of 142 mm., with a designed output of 70 to 130 B.H.P. at speeds from 1000 to 2000 r.p.m. We illustrate the larger engine herewith.

The fuel consumption at full load is about 0·40 pint per B.H.P.-hour at 1000 to 1200 r.p.m., and rises to about 0·44 pint at 2000 r.p.m. and 0·51 pint at 2500 r.p.m. Although the normal full speed is 2000 r.p.m., during trials a speed of 3000 r.p.m. has been reached on several occasions. The brake mean effective pressure developed varies from 112 lb. per square inch at 1000 r.p.m. to 108 lb. per square inch at 2000 r.p.m.

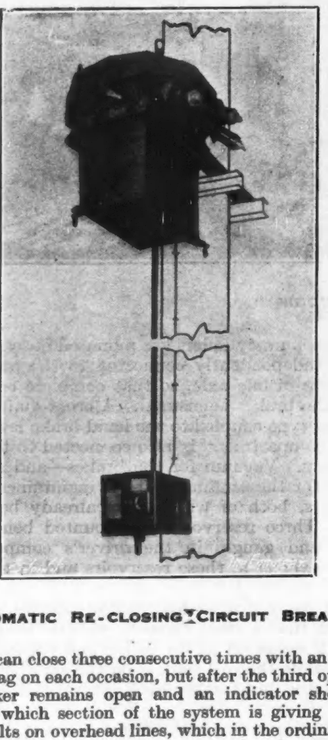
Special points in the design, which follows generally standard A.E.C.-Brooke practice, includes a cylinder casing of monobloc construction, cast in electron alloy, which is strongly ribbed to support the crank shaft. The lower casing is of cast iron with a large oil sump fitted with an oil baffle. The main bearings of the six-cylinder engine we are describing are 85 mm. diameter, with 75 mm. diameter crank pins, and a stiff crank shaft is employed with a drop forged steel connecting-rod. The bearing metal, which is lead bronze for the pressure parts and white metal for the caps, is cast into steel shells, while the small ends of the connecting-rods are of the full floating type with adjustable big ends. The pistons are made of Y metal, heat treated, and are specially long in order to avoid tipping. There are two cast iron cylinder heads, each covering three cylinders, which carry the valves, valve rockers, and the combustion chambers. A swirl chamber of the A.E.C.-Ricardo type is used with an oblique passage connecting it to the main combustion space. The fuel injection equipment is of the standard C.A.V.-Bosch pattern, which firm also supplies the 24-volt generator unit and starting motor. A gear-type circulating pump of special design is provided and the reverse gear is of the Brooke type. The six-cylinder unit, complete with reverse gear, electric starter, and exhaust manifold, weighs 2300 lb., but by using aluminium castings for the bottom half of the crank case and the reverse gear, a saving of some 200 lb. can be made, a saving of about 180 lb. being effected by a similar arrangement in the case of the four-cylinder unit, which normally weighs about 1750 lb.



130 B.H.P. Marine Oil Engine

Automatic Re-closing Circuit Breakers.

The reclosing circuit breaker mechanism, introduced by Johnson and Phillips for use in conjunction with the firm's " E.K.C." circuit breakers, was referred to in the article on the Ringmer and District Electricity Undertaking described in our issue of October 13th, but further details may prove of interest. On the occurrence of minor faults, it can close three consecutive times with an increasing time lag on each occasion, but after the third operation the breaker remains open and an indicator shows the linesman which section of the system is giving trouble. Minor faults on overhead lines, which in the ordinary way are liable to give rise to long interruptions in the supply, are therefore dealt with automatically and the risk of consumers becoming dissatisfied as the result by having to wait lengthy periods for the renewal of the supply is minimised.



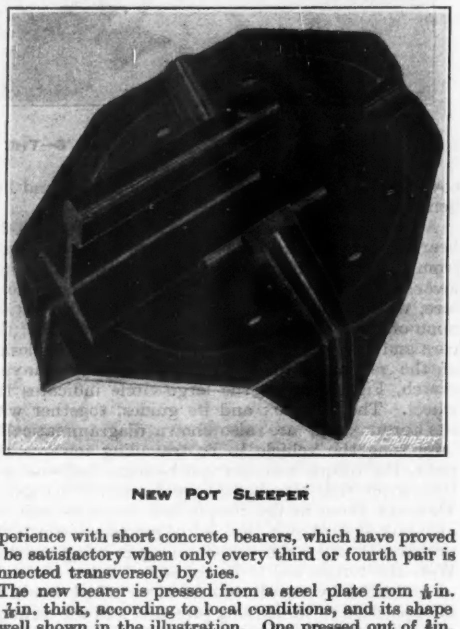
Automatic Re-closing Circuit Breaker

The mechanism is contained in a short steel box, which takes the place of the usual operating handle, and is situated near the foot of the pole, as shown in the illustration. It is wound by hand and can be set for one, two, or three reclosing operations. If an inspector finds on visiting the pole that the breaker has on some occasion tripped once or twice, but is still in circuit, he can rewind the mechanism for the full number of operations without interrupting the circuit. As the mechanism is operated purely mechanically, there is no motor or other electrical device. The energy necessary for operating the breaker is stored in a powerful scroll spring enclosed in a dust-tight case, through which the shaft to which the spring is anchored projects for the reception of the removable winding handle, which is simply turned through three revolutions. A crank at the rear of the case transmits the motion to the breaker by means of a connecting-rod, the resetting stroke being retarded by an adjustable dash-pot in order to give the requisite time delay between tripping and reclosing. The usual time lag recommended is about 30 seconds. When the breaker trips electrically, the action of the switch releases the automatic reclosing mechanism, which immediately begins the retarded resetting stroke, which is followed by the rapid closing stroke. If the short-circuit remains, the breaker trips again and is subsequently reclosed, but if after the third reclosing operation the breaker still opens it is automatically locked out, and must be reset by hand after the fault has been removed.

By means of a lever on the underside of the case, the switch can be opened at any time, and it is impossible to break the circuit slowly. By moving the lever to the left, the breaker is closed and means are provided for locking the lever in the " on " and " off " positions. An indicator in front of the case shows at a glance the number of reclosing operations for which the mechanism is set, and when the breaker is " off." Care has been taken to ensure that the apparatus cannot be interfered with by unauthorised people, and overwinding is prevented by the provision of a stop.

A New Pot Sleeper.

A new form of pot sleeper or rail bearer, which has been brought out by R. A. Skelton and Co., of Moorgate Station Chambers, London, E.C.2, is shown in the accompanying illustration. It is intended for light railways, and follows a steel sleeper of more orthodox design which was produced by the same firm last year. It is the result of experience with short concrete bearers, which have proved to be satisfactory when only every third or fourth pair is connected transversely by ties.

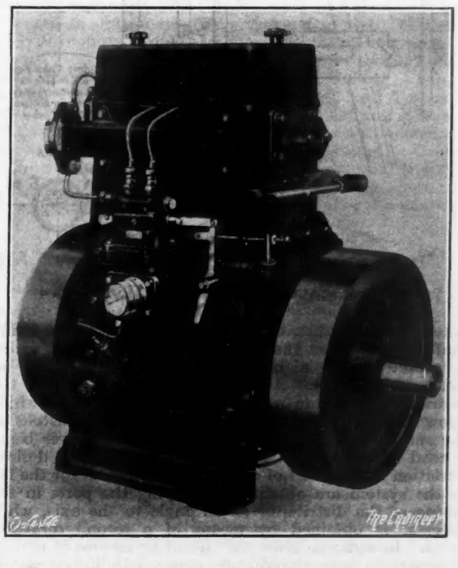


New Pot Sleeper

The new bearer is pressed from a steel plate from $\frac{1}{16}$in. to $\frac{7}{16}$in. thick, according to local conditions, and its shape is well shown in the illustration. One pressed out of $\frac{3}{8}$in. plate, measuring 2ft. by 2ft., weighs about 61 lb. The pots are protected from rusting by being dipped in bitumastic compound. They can be easily packed or tamped from any of the corners, and can be laid at wider centres than ordinary steel sleepers. They also have a longer bearing for the rail. The rail can be fixed either by long tapered keys, as shown, or the bearer can be arranged for the accommodation of a cast iron chair. The four holes provide for the bars, arranged either transversely or diagonally.

New Lister High-Speed Oil Engines.

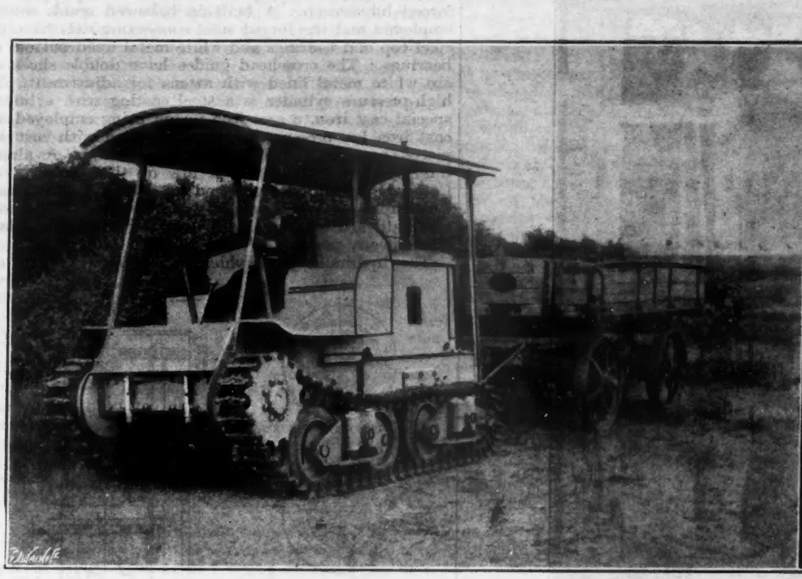
Two new units have recently been added to the range of Lister high-speed oil engines, and were exhibited on the stand of the Ruston-Lister Marine Company, Ltd., in the marine engine and motor boat section of the recent Motor Show. The larger of the two units—a twin-cylinder engine with a bore of 4½in. and a stroke of 4¾in., designed to develop 10 to 16 B.H.P. at speeds from 800 to 1200 r.p.m.—is illustrated herewith. The smaller engine is a single-cylinder unit of half the power, and it has a rating of 7 B.H.P. at 1000 r.p.m. The crank case and base plate of the new engine are cast iron, and the casing embodies the water jacket, into which the liner, which is of special iron centrifugally cast and nitrogen-hardened, is fitted. The piston is of high quality aluminium alloy, and carries four pressure rings. A combustion chamber of the Lister patented type is employed with a hand lever for compression adjustment, which lowers the compression for barring round and raises it for starting and light running. The fuel pump unit is neatly arranged on a bracket on the crank case chamber, and is directly controlled by the centrifugal governor. A pressure system of lubrication is fitted which supplies all parts of the engine, excluding the small end bearing and the cam shaft, which are splash lubricated. The full load fuel consumption is about 0·6 pint per B.H.P.-hour, and it is claimed that a wide range of fuel oils can be used. The engine has been designed either for marine or industrial services.



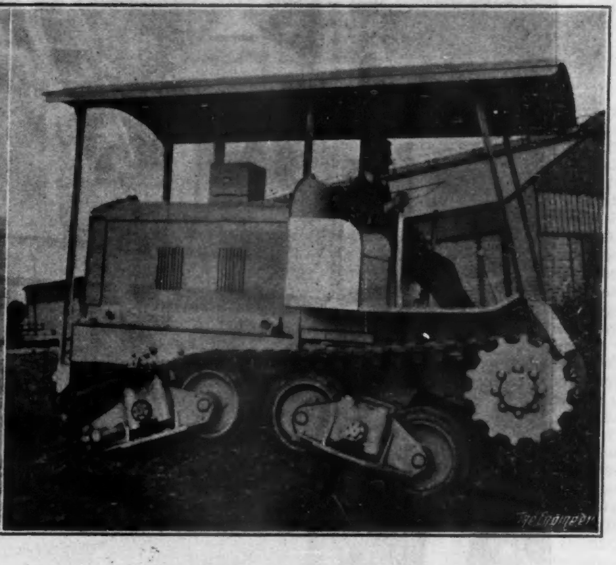
TWIN CYLINDER 10-16 B.H.P. OIL ENGINE

Oil Engine-Driven Caterpillar Tractor.

A new tractor with caterpillar tracks, just developed by Richard Garrett Engineering Works, Ltd., of Leiston, is illustrated by the accompanying engravings. Although intended primarily for use in the Colonies, it is believed that it will find many applications of an agricultural character in this country. One of its features is the provision of two gear-boxes, one of which—the main box—gives three forward speeds and a reverse, while the other provides two ratios, high and low. For ordinary light work "auxiliary" high is permanently engaged and the machine is operated entirely by means of the main box at speeds up to 12 m.p.h. But when heavy haulage is required, as in logging, "auxiliary" low is engaged and the main box then gives speeds between 1 and 6 m.p.h. A petrol, a paraffin, or an oil engine may be installed. It is mounted on a sub-frame carried on a three-point suspension system in such a way that no strain is thrown upon the engine when the tractor is traversing uneven ground. The radiator, which is of tropical type, is mounted at the rear and the fan which draws air through it is enclosed in a compartment separate from that of the engine, so that the hot air and dust has no access to the latter. Steering is carried out by the use of two independent clutches operated by two hand levers. When a lever is first moved the clutch is disengaged, and further movement applies an external contracting brake on the clutch drum. The tractor may therefore be turned very quickly. By pulling both levers hard back the brakes are applied. Four independent articulated bogies allow the tracks to conform to the contour of the ground surface. These bogies are mounted on two dead cross axles, secured to the main frame. Special round section springs fitted in plunger brackets allow the bogies to rise and fall, so absorbing vibration when running over bad surfaces, but the arrangement is such that the tractor could still operate even if a spring should break.



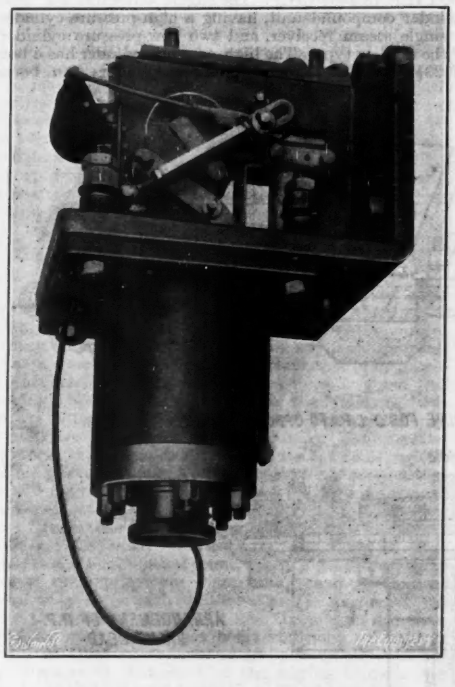
NEW CATERPILLAR TRACTOR



ARTICULATION OF THE BOGIES

Thermal Gas Closing Mechanism for Oil Circuit Breakers.

Although the practice of electrically closing circuit breakers was primarily adopted for the remote control of switchgear, it is now realised that where heavy currents have to be dealt with, and particularly under short-circuit conditions, hand closing is undesirable, and perhaps even dangerous. Some form of electrical or other closing mechanism is often advantageous, even if distant control is not desired, and Ferguson, Pailin, Ltd., of Higher Openshaw, Manchester, have therefore developed a thermal gas closing mechanism which can be applied to a circuit breaker and other arrangements which demand a rapid and powerful operating stroke. While direct-current solenoids, motor-closing mechanisms, &c., provide the power and rapid operation necessary for closing breakers under ordinary and fault conditions, it often happens that the cost of a storage battery and charging equipment or other source of electrical power is a serious item in the cost of the installation. The thermal gas closing mechanism shown in the accompanying illustration, however, merely calls for a small capacity battery, which may be of the dry Leclanche type. Alternatively, a small bell transformer may be used, and operating costs are therefore very small, and allow the device to be applied to a single circuit breaker.



THERMAL GAS CLOSING MECHANISM

The device consists mainly of one of the makers' type "C" free-handle closing mechanisms, in which the connection between the operating plunger and the circuit breaker is made by a compressed chain operating through a chain race, one side of which being removed when the trip coils operate, causes the chain to collapse and sets the breaker free to open. In the case of the mechanism under consideration, however, the usual solenoid is replaced by a steel expansion chamber, which is fixed to the "trip free" mechanism by means of a shock-absorbing device in the form of strong compression springs surrounding the bolts which clamp the broad top flange of the chamber to the underside of the base plate of the trip mechanism.

Inside the expansion chamber there is a spring-loaded plunger connected by means of the chain coupling to the circuit breaker mechanism, while in the bottom plate of the chamber there is a tapped hole for the closing element receptacle. The element consists of a cone-shaped container made of thin metal, and is filled with a small quantity of material which gasifies at a temperature of approximately 300 deg. Cent. A small heater strip or wire passes from one side of the metal container to a lightly insulated pin, which projects from the end of the cone. This pin passes through the steel plug screwed into the base plate of the expansion chamber to form the receptacle for the closing element. Connection is made to the heater by means of a flexible lead attached to a wood plug secured in position in a bayonet cap underneath the steel plug at the base of the chamber, and a spring-loaded contact on the plug makes contact with the insulated pin of the closing element.

The device is operated by passing a small current through the heater, which instantly attains a temperature of approximately 300 deg. Cent., and the rapid gas expansion which ensues propels the closing plunger and at the same time compresses the springs holding the expansion chamber to the trip mechanism. The effect is to store up some of the initial energy due to the charge, so that a fairly uniform propelling force is applied to the plunger throughout the stroke, and at the same time the expansion chamber is safeguarded against the consequences of the very high initial pressure which would otherwise be developed. A small vent at the base of the expansion chamber terminates at the end of a small bore tube with a fine gauze cage, which precludes any possibility of flame being emitted to the atmosphere, while the vent also allows the descending plunger to eject the products of combustion. The spring on the plunger is provided merely to ensure resetting of the mechanism and to complete the expansion of the gases. After each closing stroke the closing element has to be renewed, but as the elements are inexpensive and as the renewal operations can be effected in less than two minutes, this is not a real disadvantage.

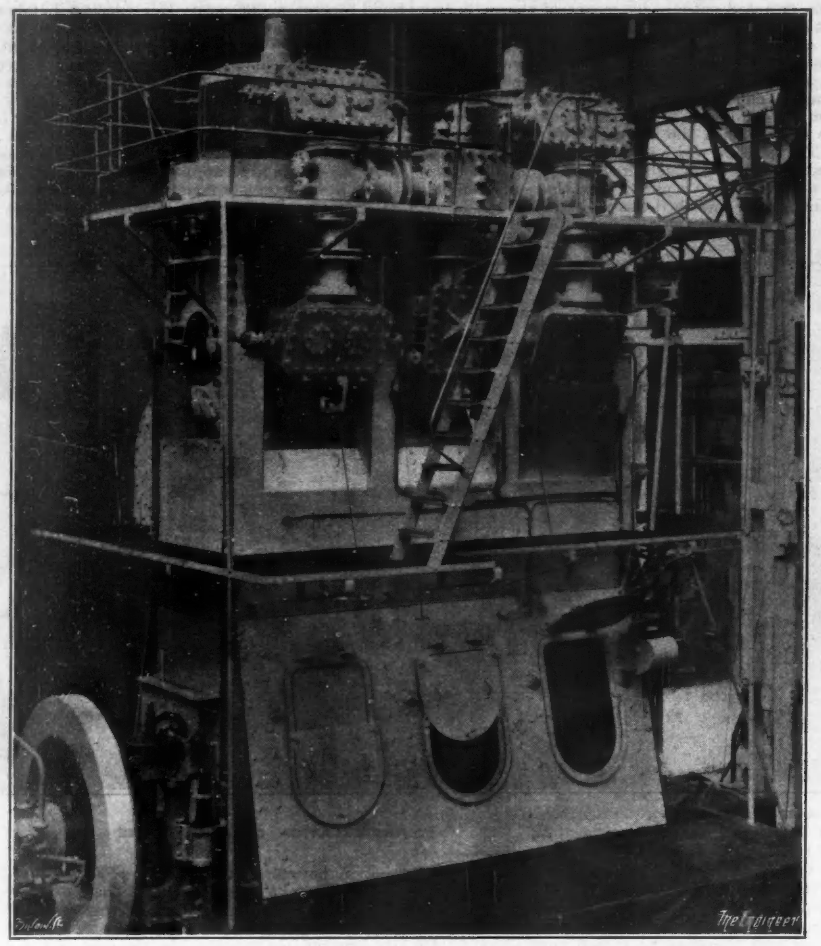
CONTRACTS.

Sir W. G. Armstrong, Whitworth and Co., of Newcastle-upon-Tyne, have received an order from Messrs. Henckell du Buisson and Co. for a 12-ton 95 B.H.P. oil-electric locomotive for use at the sugar cane plantations and works of the St. Kitts (Basse Terre) Sugar Factory, West Indies.

The Council of the Institution of Sanitary Engineers has nominated Mr. Godfrey M. C. Taylor, M. Inst. C.E., F.R. San. I., F.I.S.E., M. Inst. W.E., as President of the Institution for 1934.

THREE-CYLINDER SEMI-UNIFLOW STEAM ENGINE

ALEXANDER STEPHEN AND SONS, LTD., LINTHOUSE, ENGINEERS



2000 I.H.P. Marine Steam Engine.

On Tuesday of this week, October 24th, we were invited to attend at the Linthouse engine works of Alexander Stephen and Sons, Ltd., at Glasgow, the test bed trials of the patented "Stephen" three-cylinder compound marine steam engine, operating on the semi-uniflow principle. It has a designed output of 2000 I.H.P. The trials were continued during the three following days and will be resumed on Tuesday, November 7th, until Thursday, November 9th. The engine was exhibited in model form at the recent Olympia Exhibition, and some constructional parts of the valve gear were also shown. In what follows we describe some of the principal features of the new design, which has created a good deal of interest in marine engineering circles.

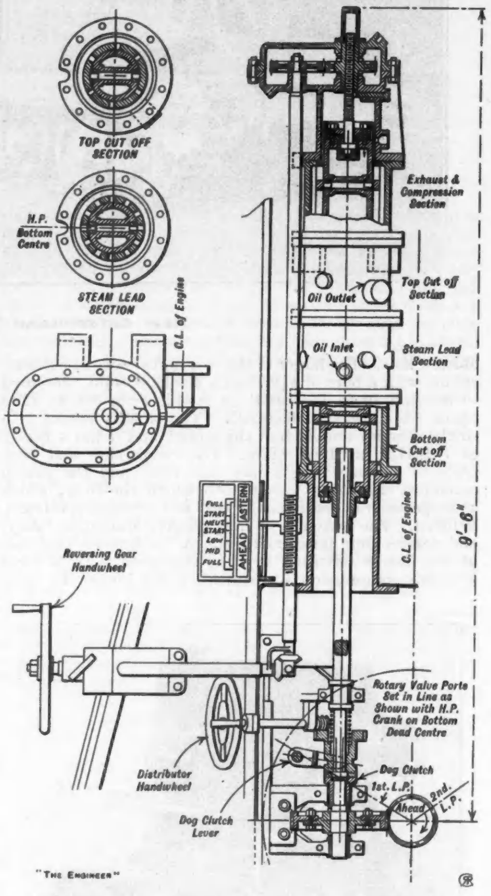
A view of the engine in the makers' works is given above, while below we reproduce drawings of the Stephen patented hydraulic valve operating gear and the low and high-pressure Andrews and Cameron slide valves. It may be recalled that the conversion of the engines of the s.s. "Annan," carried out last year, gave the designers an opportunity of investigating the possibilities of hydraulically driven Andrews and Cameron balanced slide valves. The "Annan" engine was fully described in our issue of August 19th, 1932, and its performance at sea in The Engineer of October 21st, 1932.

The new engine we are about to describe has been designed to embody the experience gained with the "Annan" engine with improvements which have resulted in a unit which is now available for powers from 500 I.H.P. to 3000 I.H.P. The engine under test is a three-cylinder compound unit, having a high-pressure cylinder, a single steam receiver, and two low-pressure cylinders of the uniflow type. The high-pressure cylinder has a bore of 23½in. and the two low-pressure cylinders 43in. bores, with a common stroke of 42in., the designed output being 2000 I.H.P. at 82 r.p.m. when supplied with steam at 230 lb. pressure and working under a vacuum of about 27in.

The constructional features include a fabricated steel frame with an all-welded crank pit. The main working stresses between the cylinders and the crank shaft are taken by heavy beams of H section, which are tied together in pairs, by the cast steel main bearing supports and the cast iron guide faces. The cylinders are rigidly held at their centres so that the top and bottom of each cylinder is free to expand, and expansion pieces of the bellows type are placed between the upper and lower valve boxes. The short crank case has a length of only 14ft. and a width of a little over 10ft., and a saving of about 20 per cent. in weight and length of the engine compared with a standard type of triple-expansion engine has been effected.

The engine is totally enclosed and is equipped with forced lubrication. A built-up balanced crank shaft is employed and the forged steel connecting-rods have cast steel top end bearings and white metal lined bottom end bearings. The crosshead guides have double shoes and are white metal lined with means for adjustment. The high-pressure cylinder is a steel casting with a liner of special cast iron, a cast iron piston being employed, and cast iron low-pressure cylinders are used with cast steel pistons carrying Ramsbottom hammered rings. As already indicated, the slide valves are of the Andrews and Cameron patented independent steam and exhaust quadruple opening balanced type with renewable seats, the hardened valve spindles working in ground glands without any packing.

The hydraulic gear, which is illustrated below, consists of a rotary distributor driven from the engine crank shaft and placed at the forward end of the engine, which is supplied with high-pressure operating oil from an independent pump. As shown in the engraving, in the distributor there are provided a number of ports which allow the oil pressure to be transmitted to small pistons on the ends of the various valve spindles, the valves being opened and closed by hydraulic pressure. The desired variation in the point of cut-off and correction for the lag in the system are obtained by sloping the ports in the casing of the distributor at an angle to the axis, while reversal is obtained by means of a second series of ports. In order to alter the cut-off or reverse it is only necessary to move the rotating plug axially in the casing. As the distributor is driven through gearing from the crank shaft and the oil pressure alone is used as a transmitter of power, the timing of the engine when once set cannot be disturbed. The discharge from the oil-operating distributor is finally led to the forced lubrication system of the engine.

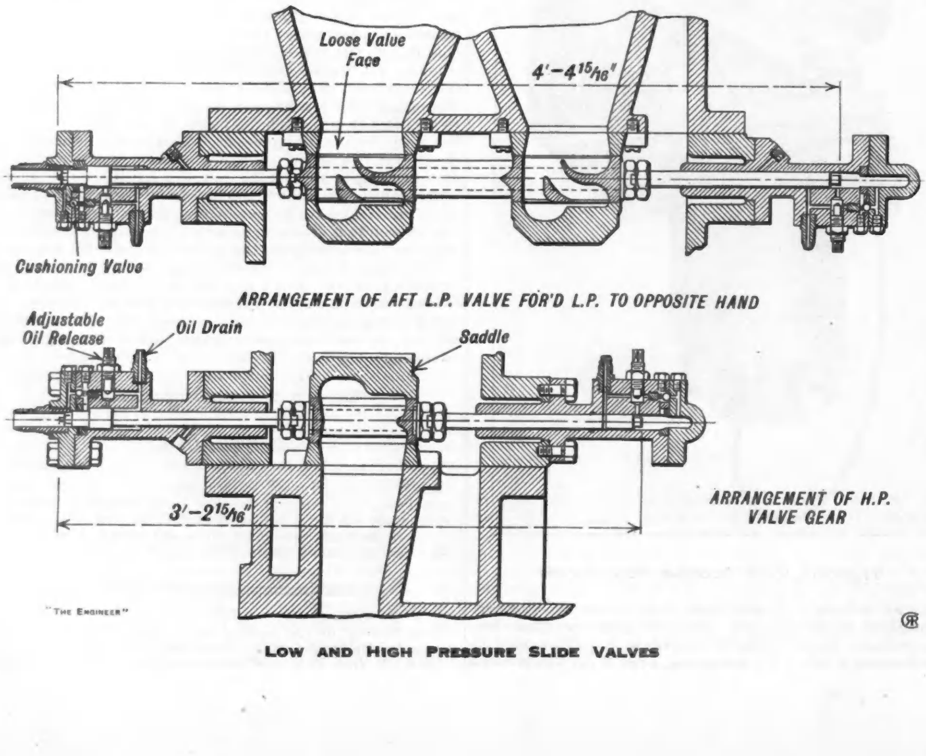


HYDRAULICALLY-OPERATED VALVE GEAR

The system is claimed to give early cut-off with quick opening and closing, while the compression and release are independent of the point of cut-off. Further, the cut-off is equal at the top and bottom of the cylinder, and the speed can conveniently be regulated by varying the cut-off. As will be seen from our illustration, a neat arrangement of control valves on the front of the engine has been arranged. The running parts and valve gear are made easy of access by means of large inspection doors and removable covers. A condenser of the regenerative type with a welded steel shell forms part of the equipment.

In a forthcoming issue we hope to give particulars of the preliminary trials.

During the last few weeks Professor A. L. Mellanby, of the Royal Technical College, Glasgow, has carried out an official set of bench trials, the results of which, it is hoped, will shortly be available for publication.



LOW AND HIGH PRESSURE SLIDE VALVES

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Steel Cartel's Difficulties.

The difficulties which beset the European Steel Cartel do not lessen with the passage of time. Although the differences between some of the merchants and the Cartel have been smoothed over, and an agreement has been reached with the Austrian, Czechoslovakian and Hungarian steel industries, limiting competition, the internal troubles of the Cartel have increased. The hostility felt by the distributors and merchants towards its sales policy, the confusion which exists with regard to prices, and the decline in the demand from the French and German home markets have combined to create something in the nature of a crisis in its affairs. The Belgian industry, which sells the greater part of its production for export, is the chief sufferer from the poor demand, and now that the French and Germans require their full share of the export trade, the comptoir responsible is faced with the impossible task of dividing the orders which come to hand in a way satisfactory to the various conflicting interests. The Belgian mills are reported to be working about three days a week, and it is natural that the steel makers strongly object to passing to other members of the Cartel orders which in the ordinary course would go to their own works. So high does feeling run that the chairman of the Clabecq Works, one of the most competitive works organisations on the Continent, told his shareholders at the annual meeting that the company had undertaken to give the Cartel a trial until the end of this year, and as a result their production had declined, their overhead charges had increased, so as to reduce profits, and they had also had to dismiss a number of workmen. If the situation did not improve, they would have to reclaim their independence. It is generally believed that if this company leaves the Cartel, the whole organisation and its selling arrangements will collapse.

A Dutch Government Contract.

The British steel makers have secured a valuable order for steel from the Dutch Government. An extensive scheme for bridge-building and bridge-repairing has been initiated in Holland which will be spread over several years, and contracts for a considerable proportion of the steel required for the first part of the programme have been placed in this country. Both high tensile and ordinary quality steel have been specified, and of the latter orders for about 2300 tons have been placed through the British Steel Export Association. It is expected that the higher quality steel requirements, amounting to about 3000 tons, will go to Dorman, Long and Co., Ltd., who will supply their Chromador steel. The Department of Overseas Trade announces that the following contracts are open for tender:—South African Railways and Harbours, twelve pump trolleys complete with wheels, axles, and ball bearings, 3ft. 6in. gauge, with a number of pressed steel wheels and axles, to be presented in Johannesburg by December 4th; steel angles, channels, flat bars, square bars, hexagon section round steel, and steel plates to specification C.M.E. 9/1930, to be presented in Johannesburg by November 13th; bolts, nuts and rivets, to be presented in Johannesburg by November 20th. A firm in Egypt requires supplies of brass wire for making hooks, 3·5 mm. and 6 mm. diameter; red copper bars, 2 cm. thick; copper flats, 15 mm. thick for rolling; wire-drawing Tombac metal bars, 2 cm. thick, and Tombac metal flat bars, 15 mm. thick. Egypt, Ministry of Education, weaving machines and accessories, also machine tools and workshop equipment, to be presented in Cairo by November 30th. Indian Stores Department, supply of ball and roller bearings for the year ending January 31st, 1935, to be presented in New Delhi by November 14th.

A Scottish Steel Plate Agreement.

The reorganisation of the Scottish steel industry has been advanced a further stage by the arrangement between Stewarts and Lloyds, Ltd., and Colvilles, Ltd., by which the latter take over Stewarts and Lloyds steel plate business in the home and export markets. Stewarts and Lloyds have manufactured plates for heavy pipe making and boiler plates at their Clydesdale Works at Mossend for some years. The agreement provides that over a period of years they will now receive the supplies they require for the manufacture of pipes from the Clydebridge Works of Colvilles, Ltd. The universal plate mill at Mossend will be converted into a blooming mill and transferred to the new steel works Stewarts and Lloyds are building at Corby, Northamptonshire. The firm will continue to develop the manufacture of large-sized tubes in Scotland, and as the capacity of the existing plate mills is in excess of the probable future demand it is expected that this concentration of production will enable a higher level of output to be reached at the Clydebridge Works. It is interesting to note that during the past few years Colvilles have, by taking over the businesses of competing firms, become of increasing importance in this branch of the steel industry, and as a result of this latest arrangement Colvilles, Ltd., and the Steel Company of Scotland, Ltd., are now the only two plate-producing interests in Scotland. It will be remembered that a year or two ago the plate business of Wm. Beardmore and Co., Ltd., was purchased and the works scrapped, whilst the plate business of James Dunlop and Co., Ltd., was also taken over by the Colville organisation. The new agreement will come into operation at the end of this year.

The Pig Iron Market.

The stocks of pig iron in makers' hands are being gradually reduced, but some time must elapse before the accumulations in some districts can be brought down to satisfactory proportions. Impatience is expressed in some quarters that the demand is not sufficient to absorb the stocks more quickly, and the old question of reviving the pig iron warrant market has been again raised. It is unlikely, however, that the pig iron producers would be unanimous on this question. It is doubtful if the makers on the North-East Coast would agree to put their stocks in warehouse and float warrants on the London and Glasgow markets, particularly as their situation so far as stocks are concerned is better than that of makers in other districts. The demand for Cleveland irons is steady and consumers have altered their attitude towards buying forward and would be willing to take more than the producers are prepared to sell owing to the advancing production costs. Good deliveries of foundry iron continue to be made to Scotland. The stocks have dropped to a level at which it is now necessary to give notice for iron which is required for shipment. In the Midlands the increased prices asked for coke and ore have once again brought to the fore the question of a possible increase in pig iron prices at the meeting of producers this week. Buying has been on a somewhat limited scale, but deliveries against contracts are being made and current business is sufficient to take care of the output. Business with the light castings foundries continues active and the heavy engineering concerns in the Midlands have shown more interest in the market. Conditions in Lancashire have also improved and there has been a tendency of late for buyers to order heavier tonnages. A certain amount of business has been done in Scottish irons at 79s. 6d. The quotation for Midland brands is unchanged, Northamptonshire foundry being 65s. 6d. West Coast hematite is quoted at 81s. In the Scottish market the demand for pig iron has been on a hand-to-mouth basis. The recent firmness which developed in the market for hematite has been maintained, and although prices have not further increased there is no inclination on the part of the makers to shade their quotations.

Finished Steel Materials.

If general business in finished steel materials is not on the scale of a few weeks ago, it has not deteriorated to a marked extent. The absence of any important new contracts has given the market a quieter appearance; but most of the steel works are busy, and the re-rollers have a considerable tonnage of work in hand. The improvement in the amount of shipping under construction is, of course, only comparative, and this industry at home and abroad is still passing through a period of depression. The figures given by Lloyd's Register of Shipping show that at the end of September the tonnage under construction in the world was 756,752 tons, of which 303,762 tons were credited to this country. Compared with the previous quarter, the figures showed an increase of 24,257 tons, of which Great Britain's share was 16,260 tons. These are encouraging figures, but the improvement must go much further before the steel makers benefit to any material extent. Even on the North-East Coast, where most departments are busy, the plate mills are short of work owing to the poor demand from the shipyards. In fact, the principal demand for shipbuilding steel comes from the repairing yards. The call for black sheets is steady, but these works also would benefit from new orders for ships. The constructional engineers on the North-East Coast are busy and Dorman, Long and Co.'s contract for the Storstrom Bridge is providing a considerable amount of work. The Scottish shipyards appear to be comparatively well employed and inquiries for new vessels are in circulation. The Scottish steel works lately have experienced an improved demand from the engineering trades, and there has been some expansion in business in tubes. Generally speaking, export trade remains unsatisfactory and the re-rollers of bars, sections, and hoops are finding competition severe from English works as well as from the Continent. The official price for re-rolled bars in this district is £7 5s. d/d Glasgow and £6 15s. f.o.b. In Lancashire the recent lull in buying has been succeeded by a demand on a fairly satisfactory scale, particularly from the constructional engineering firms. A feature of this business has been an increase in the weights ordered. The locomotive builders and the boilermakers are passing through lean times and the steel makers obtain little support from these industries. On the other hand, business in alloy steels continues to increase and the demand for bars for bright drawing is well maintained.

The Midlands, Yorkshire, and South Wales.

Conditions in the Midlands have improved lately and orders have been given out more freely than at the beginning of the month. The constructional engineers, however, do not seem to be working on any large contracts and as a consequence the demand from this branch consists of small parcels, which necessitate frequent roll changing. Some of the plate mills in the Midlands, however, are better off for work than in other districts, although the mills are by no means fully occupied. Boiler plates of either acid or basic quality are quoted at £8 5s., whilst chequer plates are at £10 7s. 6d. basis for home delivery and £10 for export. The position with regard to small steel bars is satisfactory and the re-rollers are asking rather higher figures than of late. A quotation of £7 is frequently heard and for small quantities 2s. 6d. extra is often demanded. On the other hand, when a good order is in question these prices are shaded, and recently business was taken by an English re-roller at £6 15s. in competition with a Continental seller at £6 10s., the margin in favour of the foreign material not being sufficient to make it attractive. The better demand for colliery material has been maintained, but most of the buying hitherto has been of a hand-to-mouth description. The decline in buying in the Yorkshire district was short-lived and business is again being transacted on a good scale. The call for tool steels is increasing, whilst the motor industry has provided a good outlet for special steels. The pressings and forgings departments also are more actively employed, partly on work in connection with the Imperial Chemical Company's low carbonisation plant. In South Wales the demand for tin-plates has been maintained at a high level. Recently, in one week 400,000 boxes were sold, which was well in excess of the week's production. The intimation that British (Guest, Keen and Baldwins) Iron and Steel Company, Ltd., intend to reconstruct the Dowlais Works at Cardiff at a cost of about £2,000,000 to provide a plant capable of producing 300,000 tons of billets and sheet bars per annum has created a feeling of optimism. The scheme is to be completed in about two years, and it is thought that the Cardiff Corporation will help the enterprise by giving the most advantageous terms possible in respect of the supply of water and power.

Copper.

A rather steadier tone has ruled in the copper market since the sharp fall in values towards the end of last week. After showing firmness in the face of the disturbing international political events, the market broke on a reduction in the American domestic price for electrolytic copper to 7½ c. d/d. The movement followed the strong pressure to sell by the Customs smelters in the United States, who found that at the price of 9 c., which had ruled for some time in the American market, they were accumulating stocks. Rather than do this, they broke the price. Their efforts to sell, however, were not very successful, since the fluctuations of the exchange, which occurred about the same time, made export business difficult, and consumers in the United States, as is usually the case on a falling market, were inclined to hold aloof. Continental buying has been poor, although some business has been done with Germany. The imports of copper into Germany for the first nine months of this year were estimated at 45 per cent. higher than for the corresponding period of last year, but it is believed that stocks in hand are not more than sufficient to keep consumers' works going for six to eight weeks. The German production of copper is also rising, and reached a total of 14,500 tons in September. These figures indicate the rather active conditions which have followed the German Government's development plans. The world's statistical position of the metal seems to be improving. American unofficial figures gave the stocks of refined copper at the end of September as 638,500 tons, compared with 653,000 tons at the end of August. The stocks in America on September 30th were 528,500 tons. Production of copper in the United States during September totalled 33,000 tons, whilst the rest of the world produced 63,000 tons. The London standard market speculation has decreased, and apparently most bull accounts have been liquidated. There has been some indication of bear selling, but speculation of this nature might be dangerous at the present price levels. In the early part of the week there was heavy selling on French account as a result of the political crisis in that country.

The Tin Market.

In this market the reaction which occurred last week has been followed by a firmer tone. Undoubtedly, however, the news from America has somewhat shaken confidence. The absence also of important buying by American consumers has tended to promote easier conditions in this market. It should be pointed out, however, that American dealers and consumers purchase at intervals fair quantities of tin, although the continuous buying which characterised the position a few months ago is now a thing of the past. Apart from disturbing influences arising from international, political and financial events, this market is in a strong position. Expectations that the International Tin Committee will authorise an increase in production to 40 per cent. from the present 33⅓ per cent., even if fulfilled, are not likely to exercise a depressing influence, since it is thought that the increase will not come into force until next January, and in the meantime the statistical position is steadily strengthening. Stocks in this country are being reduced, and there is talk of a possible stringency arising in the last part of the year. The demand from the consuming trades has been steady, but in many cases users have covered their requirements. German statistics show that the increased production of tin-plates in that country has been largely responsible for the heavier imports of tin which, during the first nine months of this year, were 100 per cent. higher than in the corresponding period of last year.

Lead and Spelter.

Prices in the lead market have moved within a narrow margin, although a trace of nervousness was observable in the early part of the week. Consumers are still holding aloof from the market, but it is generally thought that buying for industrial purposes will expand later in the year, as the request for manufactured lead materials is being well maintained. On the other hand, with the approach of winter building operations, which are largely responsible for the heavy demand for pipes and sheets, may be expected to slow down. It is interesting to note that producers of lead are showing more inclination to deal with merchants than for some time, and this, no doubt, has helped to keep prices steady. At one time the producers were inclined to ignore the merchants in an effort to do a direct trade, but latterly there seems to have been a change in this policy. . . . In the spelter market prices have eased somewhat in sympathy with other metals, but improved later on better advices from America regarding general conditions there. Fundamentally, however, the market is unchanged, and the statistical position is regarded as being good, all things considered. Reports from the Continent indicate that there is still a good demand for finished materials like zinc sheets, and that there has been little diminution in the consumption of spelter.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Electricity Supply.

On the occasion of the Industrial Heating Congress visits were made to the power stations at Vitry-Sud and St.-Denis, which form part of the electrical generating system around Paris, other important stations being Gennevilliers, St.-Ouen, and Issy. When the greater part of the system came under the control of the Union d'Electricité, there was a proviso that no further extensions should be made to existing stations except St.-Denis, and the new station at Vitry-Sud was laid out with a view to the installation being increased eventually to 500,000 kW. The first part of the programme was completed last year, when Vitry-Sud started with four turbo-alternators producing a total of 220,000 kW. Being the latest big power heat station constructed in this country, it is noteworthy in being equipped with the most efficient labour-saving plant and machinery procurable in France and abroad. In view of the comparison that was made at the Industrial Heating Congress between the wages bills of heat and hydro-electric plants, when it was declared that heat power generating stations were of more value to the community than the hydraulic supply, it is interesting to observe the extent to which the practically automatic working of a modern heat power plant has reduced labour to a minimum. The coal is handled by one man, and a battery of steam generators, fired with pulverised coal, is supervised by another. Although provision is made for an extension of the power station, it is by no means certain that this will be done in the near future. No one can foresee what is likely to be the consumption of electricity in the Paris district. For the moment, the supply largely exceeds the demand, and now that the quantity available from the Massif Central, Eguzon, and other hydraulic centres is expected to be supplemented in about two years' time by a further supply from Kembs, there is no necessity to proceed with the programme of extensions to Paris stations which can only be regarded as a possible contingency. Any further extension of the St.-Denis power station is held up for that reason. The old St.-Denis generating installation was put down about thirty years ago for the requirements of the Paris Metropolitan Railway, but those requirements are now served by the linking up of all the power stations in conjunction with the hydro-electric supply. The new St.-Denis power station adjoining the old one has a modern equipment similar to that of Vitry-Sud, though on a smaller scale.

Public Works.

The programme of public works comprises only a small part of the "Economic and Social Equipment" scheme which the Government has prepared, and which will be discussed in Parliament shortly. Out of the proposed total expenditure over a period of four years of 13,736 million francs, nearly one-half of which will be contributed by local bodies, the amount devoted to public works will be 2279 million francs. This will be additional to the sums provided for in the Budget estimates. These normal expenses include a contribution of 12,000,000f. towards the suppression of level crossings, and it is noteworthy that the shipping subsidies for the coming year total 126,700,000f. A large amount will also be devoted to aviation, to which a great impetus has been given since the amalgamation of the five companies into a semi-State company known as "Air-France," that has been definitely constituted with a board of directors composed of thirty-six members, including nine appointed by the State. It comprises representatives of railway and shipping companies, finance, Colonial Governments, the aircraft industry, and the Suez Canal Company. A part of the funds will be employed to equip landing grounds, and will also serve to create an air line between France and the Belgian Congo, with an extension eventually to Madagascar. This enterprise was to have been initiated a year ago in collaboration with the Belgian air organisation, but at that time the French Government was unable to ensure the service across the Sahara Desert.

Export Trade.

While the monthly returns of foreign trade continue to show a steady decline in imports and exports, the latter having contracted by 1094 million francs during the first nine months of the year, as compared with the similar period of 1932, the proportion of colonial trade included in these figures naturally becomes more important, and represents 27 per cent. of the total imports and nearly one-half of the exports. This leaves the value of exports to foreign countries during the nine months at something like 7000 million francs. The situation is so unsatisfactory that the Association des Grands Ports Français has appealed to the Government not to impose further restrictions on foreign exchanges before attempting to negotiate with other countries. Otherwise, it affirms, the policy now pursued will destroy what foreign trade there is left. The fact that France has followed the example of Sweden, Holland, and the Irish Free State in denouncing the tariff truce, implies the intention of the Government to carry through such negotiations if it possibly can.

The Steel Trade.

Instead of the customary revival of activity at this time of the year, the iron and steel trades display a decided retrograde tendency, accompanied by a decline in the pig iron and raw steel production which has, until recently, been well maintained for export. French steelmakers have exceeded their quota for the present three months, and on the home market the demand is steadily falling, to the extent that the future is not encouraging unless hope can be entertained that enterprise will revive with the heavy expenditure it is proposed to make on public works. Apart from the general financial and economic depression, there is a risk of complications within the Steel Cartel if the Forges de Clabecq should carry out its threat to withdraw from the Union at the end of the year. It is believed that, in the general interests of the steel industry, some way will be found of adjusting the difficulty.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

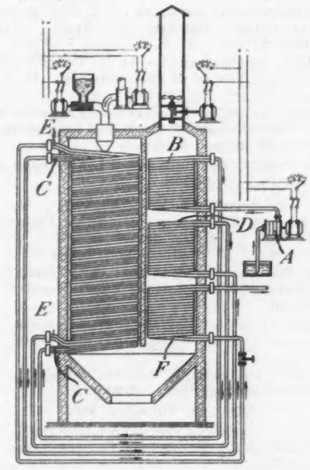
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

398,413. February 27th, 1933.—Critical Pressure Vapour Generators, Siemens-Schukertwerke Aktiengesellschaft, Berlin-Siemensstadt, Germany.

This is a rather interesting specification, in which it is explained that one of the troubles with steam generators of the critical pressure type is what might be described as "gulping" (not so mentioned in the specification); that is to say, the position in the coil of piping forming the boiler, at which the water changes from the liquid to the vaporous form, may fluctuate on account of changes in the flame temperature and length. The result is obviously a discontinuity in the steam supply. The inventors overcome the difficulty in the following manner:—Water at the necessary critical pressure is supplied to the boiler by the pump A. It is passed through a preheater B and then goes to the coil C of the main generator. After passing through this coil it goes at or about the critical temperature to the coil D, which is described as a "transition heating element." The resultant vapour returns to a parallel coil E in the main combustion chamber, and is finally superheated at F. If will be noticed that the first and second passes of the coil through the combustion chamber are subject to practically identical heating conditions, so that changes in the furnace conditions do not have a material influence on the ultimate product.—*September 14th*, 1933.

Nº398,413

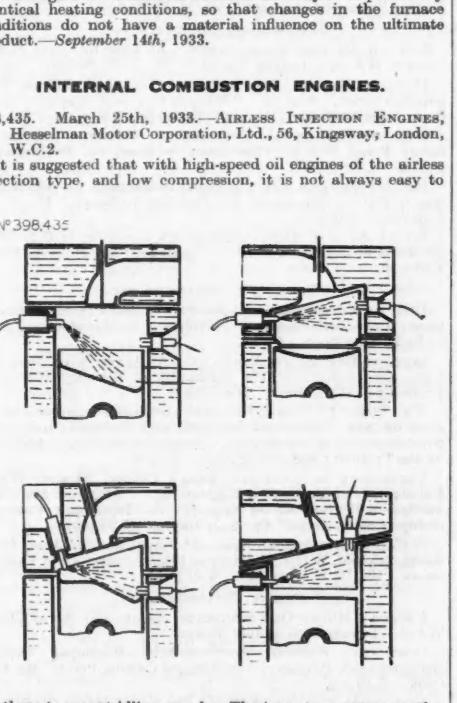


INTERNAL COMBUSTION ENGINES.

398,435. March 25th, 1933.—Airless Injection Engines, Hesselman Motor Corporation, Ltd., 56, Kingsway, London, W.C.2.

It is suggested that with high-speed oil engines of the airless injection type, and low compression, it is not always easy to get them to run at idling speeds. The inventors, consequently, suggest a combustion space formed as an obliquely truncated cylinder, with the injection nozzle towards the apex and the sparking plug at the larger end. The drawings illustrate several alternative arrangements.—*September 14th*, 1933.

Nº398,435



TRANSMISSION OF POWER.

397,539. February 23rd, 1932.—Electric Cable Systems, Siemens Brothers and Co., Ltd., of Caxton House, Tothill-street, S.W.1, and Henry Gurney Wood, of "Kinross," Leesons Hill, Chislehurst, Kent.

This specification describes a joint casing box or sleeve to be used in covering the place of jointing in a cable system, and which allows for expansions or contractions of the lead sheathing and for expansion of oil, compound, or other filling medium within the casing. The cables A may be three-core or other cables, which are prepared for jointing in the usual manner. The corrugated member B may be composed of thin metal, such as copper and is threaded on to each cable. A joint sleeve C, which may also be of thin metal, such as copper, is threaded on to one of the cables. The members B are corrugated circumferentially, as shown in section in Fig. 1, and the joint sleeve is corrugated radially, as shown in transverse section in Fig. 2. When the cable is jointed the joint sleeve C and the two members B are welded or plumbed together, as shown at D and each member D is plumbed or otherwise connected to the sheathing A of its respective cable, all jointings as D and E being leak-proof. With this arrangement longitudinal and radial expansions and contractions of the cable and of the joint filling material, due to heating and so forth, are taken up.—*August 23rd*, 1933.

Nº397,539

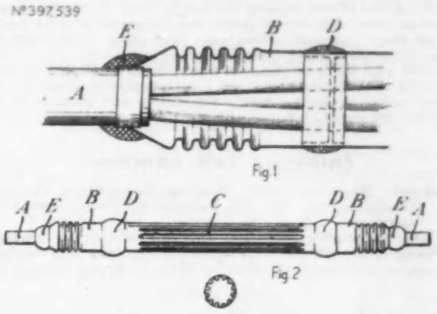


Fig 1

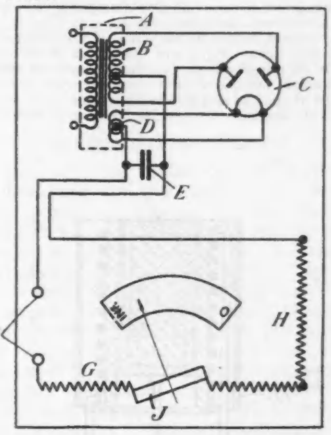
Fig 2

MEASURING AND TESTING INSTRUMENTS.

397,563. March 2nd, 1932.—Measuring Electrical Resistance, The General Electric Company, Ltd., of Magnet House, Kingsway, London, W.C.2, and Henry Cobden Turner and Arthur Sherwin, both of Salford Electrical Instruments, Ltd., Peel Works, Silk-street, Salford, Lancashire.

The megohm meter of the resistance measuring apparatus described in this specification comprises a transformer A, the secondary B of which is associated with a double-wave rectifier C. An auxiliary secondary D provides current for heating the cathode of the rectifier, and a condenser E serves for smoothing the uni-directional voltage derived from the rectifier. The test leads are connected to the terminals F. G and H are resistances, and J the moving element of a sensitive milli-ammeter with a scale calibrated at one end in thousands of ohms, and at the other end in megohms—extending to infinity. The resistance H may be adjusted to compensate for variations in the A.C. voltage. Means may also be provided for making the rectifier serve for use on mains of different voltages. As when using the apparatus no handle has to be turned, the operator can give his full attention to the test, and can manipulate the testing spikes with ease.—*August 31st*, 1933.

Nº397,563

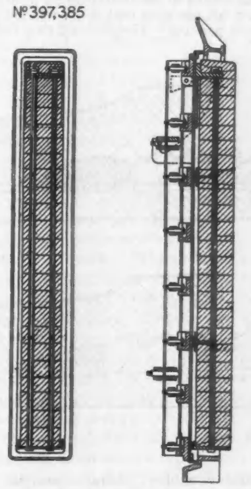


GAS PRODUCERS.

397,385. February 13th, 1933.—Coke Oven Doors, *W. W. Groves*, 30, *Southampton-buildings, London, W.C.2.*

This invention relates to a self-tightening coke oven door of the kind consisting of an outer door constructed as an elastic plate and protected on the side exposed to radiation by an inner door of fire-brick. The protecting brickwork door is suspended from a support fixed to the elastic door plate and connected with the protecting door only at the upper end thereof. The preferred support is a bracket, from which are suspended iron rods extending through the brickwork and carrying at their lower

Nº397,385



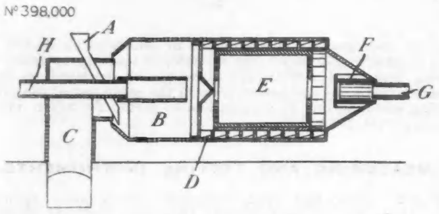
ends a supporting plate on which the weight of the brickwork rests. The brickwork may consist of separate superimposed blocks of the necessary cross section. Any iron supporting frame in which the brickwork is contained is rendered unnecessary by this arrangement so that the weight of the door is reduced. The rods are connected with the bracket in such a manner that the brickwork can swing to a certain extent about the position of rest, and by the arrangement of a suitable projection between the lower part of the door plate and the brickwork there is secured a free space between the brickwork and the elastic plate which permits bending of the door plate. Connected with the door plate are iron rods which engage by their hooked ends the rods by which the brickwork is suspended, so that undue oscillation during the closing and opening of the door is prevented.—*August 24th*, 1933.

CRUSHING AND GRINDING.

398,000. June 23rd, 1932.—Ball or Tube Mills, Ofenbau-Gesellschaft m.b.H., 105, Kaiserswerthstrasse, Düsseldorf, Germany.

This invention is concerned with ball mills of the dry type. The material to be ground is fed into the mill through the shoot A and is subjected in the chamber B to the drying action of hot gases supplied by the duct C. The material is picked up by the scoops D and fed into the grinding chamber E. The gases and suspended matter are drawn off through the filter F at G. After the suspended matter has been separated out from the gases they are returned to the circuit at H in such a zone that they do not militate against the drying action of the hot gases coming in at C.—*September 7th*, 1933.

Nº 398,000

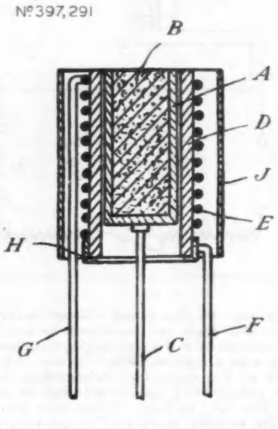


MISCELLANEOUS.

397,291. July 15th, 1932.—Electric Discharge Devices, *International General Electric Company, Incorporated, of* 120, *Broadway, New York, U.S.A.*

This invention relates to cathodes of the electron emitting and indirectly heated type, and the object of the invention is to provide an improved construction of cathode and a simple and economical method of manufacture. A is a small nickel tube closed at one end and filled with a compressed mixture B of barium oxide and tungsten powder. The small nickel tube is so positioned that its open end points in the direction in which the electron emission is to take place. The tube A has a cathode lead C, which may also serve the purpose of a support. This tube A is also surrounded by a small quartz tube D, which carries a tungsten coil E. The spiral has two current leads F and G. The lead F is attached to a wire ring H bent around the other end of the small quartz tube so that the latter is supported by the lead F. If necessary, the heating coil may be surrounded by a reflector J. The method of manufacture is described.—*August 24th*, 1933.

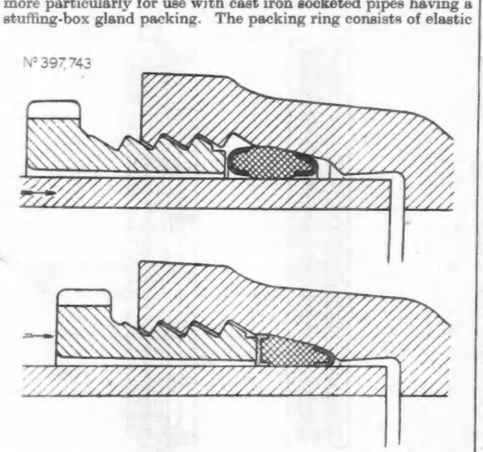
Nº 397,291



397,743. December 21st, 1932.—A Packing Ring for Pipe Joints, Vereinigte Stahlwerke Aktiengesellschaft, Breitestr. 67/69, Düsseldorf, Germany.

This invention relates to packing rings for pipe joints intended more particularly for use with cast iron socketed pipes having a stuffing-box gland packing. The packing ring consists of elastic material, preferably rubber, characterised in that its cross section has substantially the shape of a rhombus whose opposite corners, which are in transverse relation to the axis of the ring, become deformed when it is inserted in the stuffing-box and before the stuffing-box gland packing is tightened. The packing is, of course, made still more complete when the stuffing-box gland is inserted in the already known manner. In order to protect the packing from damage, either by the contents of the pipe or by the pressure of the stuffing-box gland, and also in order to facilitate the insertion of the latter, the axially directed edges of the ring are covered with an outer lining of a deformable material, such, for example, as lead. The illustrations show the packing before it is deformed and after the gland has been tightened up.—*August 31st*, 1933.

Nº 397,743



Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the* TIME *and* PLACE *at which the meeting is to be held should be clearly stated.

Inst. of Structural Engineers: Midlands.—James Watt Memorial Inst., Birmingham. Chairman's address, Mr. E. L. Cotterell. 6.30 p.m.

Inst. of Electrical Engineers: N.E. Centre Students.—At Armstrong College, Newcastle-upon-Tyne. "The Dunston 50-cycle Power Station," Mr. A. S. Carr. 7.15 p.m.

Junior Inst. of Engineers.—At 39, Victoria-street, S.W.1. "The Electrolytic Theory of Corrosion," Mr. H. E. Yerbury. 7.30 p.m.

Manchester Assoc. of Engineers.—Engineers' Club, Manchester. "The Selection of Steels for Engineering Requirements," Mr. F. W. Rowe. 7.15 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. Discourse, Mr. E. V. Appleton. 9 p.m.

Saturday, October 28th.

Hull Assoc. of Engineers.—Municipal Technical College, Park-street, Hull. "Experimental Research on Boundary Lubrication," Mr. J. E. Southcombe. 7.30 p.m.

Inst. of British Foundrymen.—The Technical College, Derby. "Technical Control in the Small Foundry," Mr. J. G. Pearce. 6 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

Stephenson Locomotive Society.—Visit to Stratford, L.N.E. Railway Running Sheds. 2.30 p.m.

Monday, October 30th.

Bradford Engineering Soc.—Technical College, Bradford. "Salvage Work on the Ex-German Fleet at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Inst. of Automobile Engineers.—At 39, Elmbank-crescent, Glasgow. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 7.30 p.m.

Inst. of Mechanical Engineers: Graduates.—Storey's-gate, S.W.1. "Stainless Steels in Aeroplane Structures," Mr. F. J. Murdoch. 6.45 p.m.

Tuesday, October 31st.

Inst. of Transport.—At Inst. of Electrical Engineers, Victoria Embankment, W.C.2. Discussion, "The Duties of a Modern Transport Manager," Mr. M. F. Barnard.

Wednesday, November 1st.

Inst. of British Foundrymen.—At Charing Cross Hotel, London, W.C.2. "Cupola Practice," Mr. L. W. Bolton. 8 p.m.

Inst. of British Foundrymen.—Technical College, Corporation-street, Preston. "Manufacture and Application of Centrifugal Castings," Mr. T. R. Twigger. 7.30 p.m.

Inst. of Electrical Engineers: Wireless Section.—Savoy Place, W.C.2. Chairman's address, Mr. G. Shearing. 6 p.m.

Inst. of Physics.—In the Royal Institution, 21, Albemarle-street, W.1. "Physics in the Building Industry," Dr. R. E Stradling. 5.30 p.m.

Royal Soc. of Arts.—John-street, Adelphi, W.C.2. Presentation of medals. Address, "Quality," Mr. John A. Milne. 8.30 p.m.

Thursday, November 2nd.

Inst. of Automobile Engineers.—Queen's Hotel, Birmingham. Presidential address, "Problems in Manufacture," Mr. C. R. F. Engelbach. 8 p.m.

Inst. of British Foundrymen.—At James Watt Memorial Inst., Birmingham. "The Education of Foundry Workers," Professor J. H. Andrew. 7.30 p.m.

N.E. Coast Inst. of Engineers and Shipbuilders: Teesside Branch.—Cleveland Scientific and Technical Inst., Corporation-road, Middlesbrough. Inaugural meeting. Addresses by the President and Chairman. 7.30 p.m.

University of London.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: iii., Injection: Processes in Injection Systems," Dr. S. J. Davies. 5.30 p.m.

Royal Aeronautical Soc.—At Royal Soc. of Arts, John-street, Adelphi, W.C.2. "Variable Pitch Airscrews and Variable Gears," Mr. W. G. Jennings. 6.30 p.m.

Friday, November 3rd.

Faraday House Old Students' Assoc.—At Savoy Hotel, W.C.2. Twenty-fifth annual dinner.

Inst. of British Foundrymen.—Municipal College, Ormerod-road, Burnley. "Continuous Casting Plant," Mr. F. J. Cook. 7.15 p.m.

Inst. of Marine Engineers.—Grosvenor House, Park-lane, W.1. Annual conversazione. 7 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Thomas Hawksley Lecture, "Kinematic Design in Engineering," Professor A. F. C. Pollard. 6 p.m.

Inst. of Production Engineers: London Section.—83, Pall Mall, S.W.1. "Modern Production Acetylene," Mr. C. Helsby. 7.30 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "Safety and Efficiency in Electrical Installation Work," Mr. W. F. C. Cooper. 7.30 p.m.

N.E. Coast Inst. of Engineers and Shipbuilders.—In Literary and Philosophical Society's Lecture Theatre, Newcastle-upon-Tyne. Andrew Laing Lecture, "Recent Metallurgical Developments and their Significance for Shipbuilding and Marine Engineering," Prof. F. C. Lea. 7 p.m.

Railway Club.—57, Fetter-lane, E.C.4. "Train Ferries: Their History and Development," Mr. S. R. Yates. 7.30 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. Discourse, Sir Arthur Hill. 9 p.m.

Saturday, November 4th.

Inst. of British Foundrymen.—At Engineers' Club, Manchester. "Continuous Casting Plant," Mr. F. J. Cook. 4 p.m.

Inst. of Electrical Engineers: North Midland Students.—Visit to the Hunslet Engine Company, Ltd., Jack-lane, Leeds. Meet at Corn Exchange, Leeds, 2.30 p.m.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

Monday, November 6th.

Soc. of Engineers.—In the Rooms of the Geological Soc., Burlington House, W.1. "Nasmyth: Father and Son," Mr. John Wilkie. 6 p.m.

Wolverhampton and District Engineering Soc.—The Co-operative Hall, Stafford-street, Wolverhampton. The Thomas Lowe Gray Lecture, "Eight Years' Salvage Work at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

Tuesday, November 7th.

Inst. of Engineers and Shipbuilders in Scotland.—39, Elmbank-crescent, Glasgow, C.2. "Liquid Fuels from Coal for Naval Purposes," Eng.-Capt. S. H. Dunlop, R.N. 7.30 p.m.

Inst. of Metals: Birmingham Local Section.—In the Girls' High School, Dudley. "The Interpretation of a Photomicrograph," Mr. J. W. Jones. 7 p.m.

Tuesday and Wednesday, November 7th and 8th.

Inst. of Gas Engineers.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. Fifth autumn research meeting. Morning sessions, 10 a.m.; afternoon sessions, 2.30 p.m. (See page 406.)

Wednesday, November 8th.

Soc. of Glass Technology: London Section.—Visit to Canning Town Glass Works, Stephenson-street, Canning Town, E.16. 7.30 p.m.

Thursday, November 9th.

Chemical Engineering Group.—Joint meeting with the Oil and Colour Chemists' Assoc. at Inst. of Chemistry, 30, Russell-square, W.C.1. Discussion, "Function of Paint as a Metal Preservative." Opener, Dr. L. A. Jordan. 7.30 p.m.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. Junior Section. "Pumps for Marine Service," Mr. F. M. Jones. 7 p.m.

Inst. of Civil Engineers: Birmingham and District Assoc.—At James Watt Memorial Inst., York House, Birmingham. "Rainfall as of Interest to Engineers," Mr. A. A. Barnes. 6 p.m.

Inst. of Structural Engineers: Yorkshire.—Hotel Metropole, Leeds. "Designing for Welding," Mr. C. Helsby. 7 p.m.

Inst. of Metals: London Local Section.—At Royal School of Mines, S. Kensington. "Gold—its Sources and Production," Mr. R. Annan. 8 p.m.

University of London.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: iv., Injection: Processes in the Cylinder," Dr. S. J. Davies. 5.30 p.m.

Friday, November 10th.

Inst. of British Foundrymen.—At the Cleveland Scientific and Technical Inst., Corporation-road, Middlesbrough. "Routine Methods of Testing Green Sands," Mr. N. D. Ridsdale. 7.45 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Informal meeting. Discussion, "Financing Industry," introduced by Mr. Sydney Parkes. 7 p.m.

Inst. of Metals: Sheffield Local Section.—In Non-ferrous Section of Applied Science Department of University, St. George's-square, Sheffield. "Metal Spraying," Mr. W. E. Ballard. 7.30 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. Annual general meeting. 7.30 p.m.

Saturday, November 11th.

Inst. of British Foundrymen.—Technical College, Monks-road, Lincoln. "Use of Refractory Materials in the Foundry," Dr. J. G. A. Skerl. 7 p.m.

Inst. of Marine Engineers: Junior Section.—85–88, The Minories, E.C.3. Social and dance. 7.30 p.m.–11.15 p.m.

Inst. of Mech. Engineers: Graduates.—Visit to Brookman's Park Wireless Station. Particulars from Hon. Sec., Graduates' Section, 28, Essex street, Strand, W.C.2.

Monday, November 13th, to Saturday, November 18th.

Public Works Congress and Exhibition.—Agricultural Hall, Islington, N.1. Daily. (For programme see page 365).

Monday, November 13th.

Inst. of Metals: Scottish Local Section.—At Inst. of Engineers and Shipbuilders in Scotland, 39, Elmbank-crescent, Glasgow. Discussion on papers presented at the autumn meeting of the parent Institute. 7.30 p.m.

Tuesday, November 14th.

Chemical Engineering Group.—At the Public Works, Roads, and Transport Exhibition, Royal Agricultural Hall, Islington, N.1. Conference, "The Mechanical Testing of Bituminous Road Materials." Sessions 11 a.m. and 3 p.m.

Inst. of Marine Engineers.—85–88, The Minories, E.C.3. "Welding for Pressure Vessels," Mr. R. Sulzer. 6 p.m.

Inst. of Metals: Birmingham Local Section.—In James Watt Memorial Inst., Birmingham. "Deoxidisers and Fluxes," Mr. G. L. Bailey. 7 p.m.

Inst. of Metals: N.E. Coast Local Section.—Joint meeting with the Newcastle-upon-Tyne Branch of Soc. of Chemical Industry, in Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-upon-Tyne. "Metal Spraying," Mr. W. E. Ballard. 7.30 p.m.

Inst. of Metals: Swansea Local Section.—At Y.M.C.A., Swansea. "Ageing and Age Hardening," Dr. Cecil H. Desch, F.R.S. 6.15 p.m.

Wednesday, November 15th.

Inst. of Electrical Engineers: Meter and Instrument Section.—Pagani's Restaurant, 42, Gt. Portland-street, W.1. Annual dinner. 6.45 p.m. for 7 p.m.

Manchester Metallurgical Soc.—At College of Technology, Manchester. "Hardness of Metals," Dr. H. O'Neill. 7 p.m.

N.E. Coast Inst. of Engineers and Shipbuilders: Graduates.—Bolbec Hall, Newcastle-upon-Tyne. "Leaves from an Engineer's Log," Eng.-Comr. C. J. Hawkes, R.N. 7.15 p.m.

Thursday, November 16th.

British Waterworks Assoc.—Agricultural Hall, Islington, N.1. To receive and discuss the following papers:—"Pooling of Supplies by Interconnection of Water Undertakings and their Trunk Mains through Rural Areas," Mr. Alan E. L. Chorlton; "Water Pollution Research," Dr. A. Parker. 11 a.m. Afternoon session: "The Financial Management of Municipal Trading Departments," Mr. Sydney Larkin; "Water Supply and Fire Protection," Mr. John Smith; "Fire Prevention and Fire Extinguishing Apparatus," Major F. W. Jackson; "The Legal Aspect of Water Supply for Fire Protection Purposes," Mr. John Hall. 2.45 p.m.

A Seven-Day Journal

Cast Iron Research.

The report of the British Cast Iron Research Association, which has just been issued, reviews the progress made during the last year, and shows a steady increase in the volume of work performed. The increased laboratory accommodation at headquarters has been of great assistance in advancing the work undertaken, and quite recently more floor space for laboratories has been acquired and will enable the Association to meet normal requirements for some years to come. By the offer of Mr. H. James Yates, the chairman of Radiation, Ltd., and a Vice-president of the Association, to provide funds to erect an experimental cupola furnace, a long-needed want has now been met. The furnace will be erected at a small foundry near to the laboratories under conditions which will enable it to be operated on an experimental basis at any time, without the necessity of the Association permanently maintaining the manual labour. The new facilities which the furnace will offer will, it is expected, greatly advance the value of the work carried out, not only by the Melting Practice Subcommittee, but also of other sub-committees of the Association. The new President of the Association is Major F. A. Freeth, D.Sc., F.R.S., of Imperial Chemical Industries, Ltd., who has consented to accept the office lately relinquished by Sir Harold Hartley. In view of the extensive application of cast ferrous metals and alloys in the chemical industry, Dr. Freeth's appointment would seem to be a most appropriate one. The re-elected chairman of the Association is Mr. H. B. Weeks, F.I.C., and the Vice-chairmen Mr. J. T. Goodwin and Mr. F. J. Cook, M.I. Mech. E.

The Parliamentary Science Committee.

The idea of establishing a liaison body between Science and Parliament has found considerable support during recent years, and was particularly discussed at the recent British Association meetings held at Leicester. The idea has now taken shape, and at meetings of the British Science Guild and the Association of Scientific Workers, which were held in London last week, it was decided to form a Parliamentary Science Committee. Each of those two organisations is represented on the Committee, to which have been added representatives of other bodies concerned. The following scientific institutions and associations have promised their support :—The Institution of Mechanical Engineers, the Institution of Naval Architects, the Institute of Metals, the Institute of Physics, the Royal Institute of British Architects, the Society of Engineers, the Pharmaceutical Society of Great Britain, the Institution of Professional Civil Servants, the Joint Council of Qualified Opticians, the South-Eastern Union of Scientific Societies, and the Oil and Colour Chemists' Association. For the present the Committee is confining its attention to exploring and forwarding the subjects actually under preparation for Parliament by constitutional bodies. The Committee will meanwhile continue the periodical issues of "Science in Parliament," which is a summary of all parliamentary procedings affecting science collated from Hansard, and adequately indexed, from the opening of the 1932–33 session. The Chairman of the Executive Committee is Commander B. W. Bernacchi ; the Vice-chairman, Professor B. W. Holman ; and the joint hon. secretaries, Mr. A. Howard and Mr. W. J. Stone. The headquarters of the Committee are the British Science Guild, 6, John-street, Adelphi, W.C.2.

A New "Grid" Tariff.

Last week the grid tariff for the South-East England and East England areas was issued by the Central Electricity Board. It is well known that these tariffs for the various areas consist of a fixed kilowatt charge and a running charge, both subject to certain variations. In the former case the variations are governed by power factor and rates, and in the latter by the cost of fuel. With the object of stimulating the development of load, a progressive reduction of the kilowatt charge is made as the demand of an undertaking increases, in the manner described in our issue of December 2nd, 1932. The new tariff takes the usual form, and as regards service charge, fixed kilowatt charge in respect of each point of supply, and the variations of the fixed charge with power factor, it conforms in every respect with the previous tariff. Certain monetary values, however, apply to the new tariff alone. Engineers interested in these tariffs no longer need an explanation of all the details, and it will suffice to say with regard to the variation governed by rates that the fixed kilowatt charge is increased or reduced by the amount of 1s. 10d. for each shilling above or below 4s. 3d. as arrived at by the usual formula. For each kilowatt supplied and taken during the year the sum of 0·21d. is to be paid, and if the coal cost calculation gives a sum more or less than 16s., the running charge will be increased or reduced in the year by 0·0008d. for each penny by which the sum is above or below 16s. A halfpenny or any greater part is treated as one penny, whilst in the case of the rates variation of the fixed charge a *pro rata* increase or reduction is made for any part of one shilling. Trading operations, in accordance with the provisions of the Electricity Act, 1926, will begin under the tariff on January 1st, 1934.

Sheffield and Armaments.

An official statement with regard to the present activities connected with armament manufacture in Sheffield was issued by the Sheffield Chamber of Commerce on Monday last. The true facts, it states, are that during the last few years the normal programme of building in Great Britain has been cancelled and has not been reconsidered recently, in anticipation of a successful conclusion to the Disarmament Conference in Geneva. Replacement of ships and material, however, is greatly in arrears, and this accounts for the present slightly increased activity in many Sheffield concerns. Actually authentic figures show that not more than 20 per cent. of the turnover of the large steel firms is represented by armaments, and of this percentage a large proportion includes quantities of marine propelling machinery for warships being constructed under the ordinary programmes. With regard to the remaining 80 per cent. capacity this is represented by work in connection with large schemes for oil extraction from coal, the mercantile marine, alloy steels for motor cars, and stainless steel.

L.N.E.R. Development Schemes.

The London and North-Eastern Railway Company announced on Tuesday last that in consequence of the return of better trade conditions throughout its system, and in order to enable it to meet the possible requirements of a revival of industry, its directors had authorised a series of development programmes involving the expenditure of £2,300,000. Eighty new locomotives are to be constructed, nine of which will be of the 4–6–2 "Pacific" type at present used on the "Flying Scotsman" services. In addition, five 4–6–0 passenger locomotives of the "Sandringham" class for East Anglian services, twenty-five 4–4–0 passenger engines of the "Shire" class for the North-Eastern area, twelve 0–6–0 freight class, and ten 2–6–0 mixed traffic engines for the North-Eastern area are to be built. Five passenger locomotives of the 2–8–2 type are to be made for express services between Edinburgh and Aberdeen. Ten 2–6–2 tank engines for the North of England, and ten 4–4–4 tank engines are to be converted into a new 4–6–2 "Pacific" type tanks to assist the working of mineral traffic in the Durham district. Authority has also been given to proceed with the construction of fourteen locomotives, six of the 2–6–2 tank type for Scotland and eight 2–8–0 engines for East Anglia. The carriage and wagon programme includes sixty-two new carriages and 5579 wagons. The complete renewal of forty-three bridges and the renewal of 371 miles of track with the renovating of a number of stations will all be carried out during 1934.

The Late Mr. Hartley Grunwell.

We regret to have to record the death on Thursday, October 26th, of Mr. Hartley Grunwell, A.M. Inst. C.E., of Oakroyd-terrace, Manningham, Bradford, who for the past twenty-three years acted as inspecting engineer for the Port of London Authority. Mr. Grunwell was born at Farsley, and after attending the Fulneck Commercial School, was apprenticed to John Butler and Co. at Stanningley Ironworks, near Leeds. After a period of twenty years with the same firm, during which he became chief engineer of the mechanical department, and was entrusted with the carrying out of some of the largest contracts, Mr. Grunwell left for Glasgow, where he was appointed the assistant manager of James Goodwin and Co., a firm of bridge builders and general engineers. Six years later he took up a position on the executive engineering staff of the Glasgow Subway. In 1928 he joined S. Pearson and Co., Ltd., of Westminster, and was appointed Chief Mechanical Engineer on the Admiralty Harbour contract at Dover. For some time afterwards, he was at the company's Westminster office, after which he started his own business in Bradford as an inspecting mechanical and civil engineer.

New Dock at Belfast.

On Thursday, October 26th, the new dock and channel constructed by the Belfast Harbour Authority on the Antrim side of the harbour, was formally opened by the Duke of Abercorn, the Governor of Northern Ireland. The naming ceremony was gracefully performed by Princess Alice, Countess of Athlone, who named the channel the Herdman Channel, after Mr. R. E. Herdman, the present chairman of the Belfast Harbour Board, and the dock the Pollock Dock, after Mr. H. M. Pollock, the Minister of Finance and the former chairman of the Harbour Commissioners. The new works consist of a dock and turning basin on the site of the old timber ponds and a new channel, about a mile and a half in length, leading direct from the main Victoria Channel. The extent of the new dock is about 2600 linear feet—1020ft. with a depth of 30ft. at low water, and 1580ft. with a depth of 23ft. at low water. The Belfast Harbour now consists of three main channels—the centre Victoria Channel, with a number of docks running from it ; the Musgrave Channel, on the Co. Down side of the Lagan ; and the new channel and dock on the Co. Antrim side. As an indication of the traffic increase, it may be stated that the net tonnage which entered the port in 1921 was just over 5,000,000 tons, and in 1932 it was 7,500,000 tons. The goods imported in 1921 amounted to 2,250,000 tons, and in 1932 to over 3,000,000 tons.

"Grid" Electricity Schemes.

An official statement of the Central Electricity Board concerning the South-East England and East England schemes explains that, although the two area schemes were adopted and carried out as separate parts of the "grid" system, the Board has decided that for the purpose of trading they shall be treated as one. Electricity will be produced in the combined area in thirty-seven selected stations, including four new stations. Of the latter, Battersea is in the process of being put into commission, Fulham is under construction, and no decision has been taken regarding the other two. Among the principal stations are Barking, Deptford West, Brighton, Brimsdown, West Ham, Croydon, Stepney, Hackney, Bankside, and Norwich. Together with eighty-eight transforming and switching stations the power stations are interconnected by 1029 miles of transmission lines, of which 690 miles, including 15 miles of cable in the London area, are operated at 132 kV, and 399 miles, including 102 of cable, at lower voltages. Extensions to the north and west link up the area with the Mid-East England, Central England, and South-West England and South Wales scheme areas. The area to which the new tariff, referred to in another note on this page, will apply, extends to 12,266 square miles lying between the Wash and the South Coast, with the towns of Peterborough, Bedford, Reading, and Littlehampton, marking roughly the western boundary, and, including London, contains a population of approximately 13½ millions, or over 29 per cent. of the entire population of the United Kingdom. The total amount of electricity generated by authorised undertakings in the area last year was just over 4000 million units.

The Orient Line Fleet.

The managers of the Orient Line to Australia—Anderson Green and Co., Ltd., of Fenchurch-avenue, London—announced on Monday last that they had invited tenders for the construction of a new mail and passenger vessel for the company's Australian service. It may be recalled that the fleet now comprises five 20,000-ton liners of the "Orama" class, and two smaller tourist liners, the "Ormonde" and "Orsova." The 20,000-ton liners are propelled by geared turbine machinery with oil-fired boilers, and are noteworthy for their well-planned passenger accommodation. Speaking at Barrow-in-Furness on Saturday last, Commander C. W. Craven, the managing director of Vickers-Armstrongs, Ltd., referred to the Orient Line inquiry, and stated that it would be for a larger and better ship than the older ships which Vickers had constructed for the company.

Shipbuilding Rationalisation.

In the course of an address given by Mr. F. C. Pyman, of William Gray and Co., Ltd., West Hartlepool, to the West Hartlepool Rotary Club, on Monday, October 30th, some interesting figures regarding redundant shipbuilding capacity and the efforts made by National Shipbuilders' Security, Ltd., to meet the loss thus incurred were given. Ever since 1923, Mr. Pyman said, the industry had not been able to utilise more than half its capacity, and often in the last decade 25 to 30 per cent. was all that was needed, often nine out of ten berths being empty. The function of National Shipbuilders' Security, Ltd., was to offer a market for such yards at a price substantially above scrapping price, and to prevent yards falling into the hands of bargain hunters. The scheme had been in operation three years. In January, 1930, there were 684 berths, of which 43 had ceased to count, while a further 116 berths had been purchased, making a total reduction of 159, or, say, 25 per cent. Of the 684 berths, rather more than half were engaged in building cargo vessels, and that capacity had been cut down by 30 per cent. Less than one-quarter of the 684 were passenger liner or warship berths, and that capacity had been cut down by 7 per cent., while the remaining berths were normally engaged in the building of small craft. Efforts had been made to observe due apportionments between the various shipbuilding areas. The Clyde had so far sacrificed more than the North-East Coast, the percentages being 18·68 for the Clyde and 12·85 for the North-East Coast. The method of sterilising shipbuilding sites for forty years had been regarded as harsh, but what other method was available ? In any case, the company was making every effort to attract new industries to the demolished sites, and the present prospects of placing such sites were good. Mr. Pyman concluded by saying that if he had persuaded his hearers that the shipbuilders were tackling the problem wisely and courageously, and that the job might safely be left in their hands, then he was satisfied.

New Methods of Excavating Quicksands.*

By Sir HENRY JAPP, K.B.E., M. Inst. C.E., M. Soc. C.E. (France).

No. II.

(Concluded from page 402, October 27th.)

JOOSTEN CHEMICAL CONSOLIDATION PROCESS.

THE chemical consolidation process was discovered by Dr. H. Joosten in his work for Gebhardt and Konig, of Nordhausen, Germany, during his management of their potassium and salt mines. He found that the large accumulation of brine met with in seams and pockets during the excavation was a great source of danger, and by impregnating the ground with sodium silicate both the soil and the liquid were made into a hard mass by the combination of the sodium silicate with the brine. Patents were taken out for the application of this method in 1925 and 1926 as applied to the chemical solidification or petrification of loose soils.

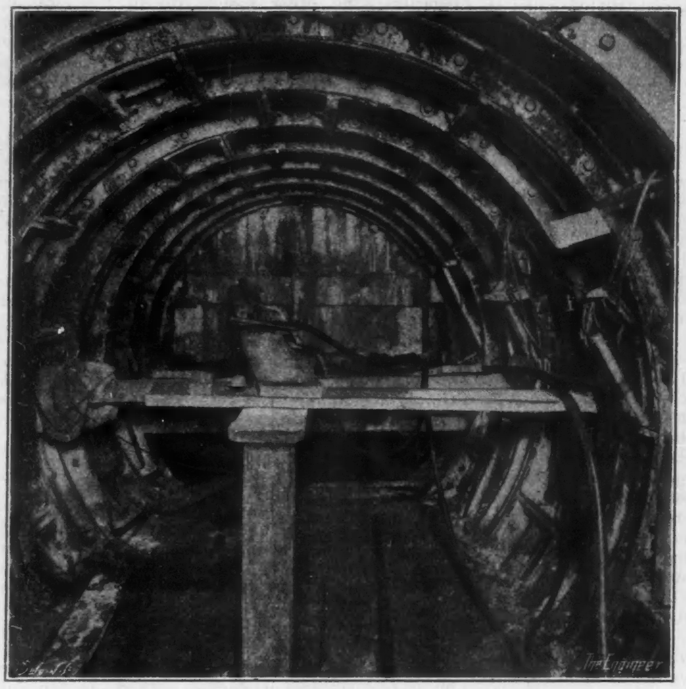

FIG. 18—MONUMENT STATION SEWER DIVERSION TUNNEL, CLOSE-BOARDED FACE

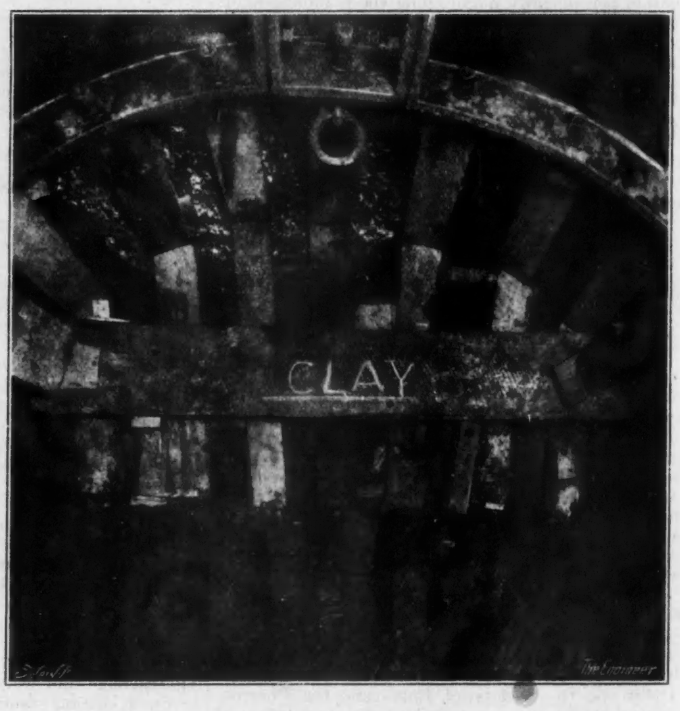

FIG. 20—SEWER DIVERSION TUNNEL AFTER CHEMICAL CONSOLIDATION

The great advantage of this process is that it is possible to transform loose sandy gravel in a shaft or tunnel heading into a permanent solid layer impervious to water. This method is, therefore, most useful for cutting off a flow of water where it is present, and making loose sand and gravel into a solid watertight material. The consolidation or petrification takes place at once, and requires no time for setting. As the chemicals are dissolved in water, forming a solution of one and a half times the specific gravity of water, they are able to penetrate wherever water may be, first driving the water before them without being diluted and then combining in a solid mass. This feature is an important one when compared with present methods of attempting to force fine cement grout into the minute interstices of sand or gravel. The cement is more likely to be filtered out and left to set in hard globular lumps without reaching the fine interstices and accomplishing its purpose. It is immaterial whether the sand is dry or under high water pressure, as the chemical consolidation process is adaptable to either condition. The process converts sand and ballast into a condition resembling a sandstone or conglomerate, and the impregnation can be carried on at almost any pressure to suit the head of water in the ground, pressures as high as 1400 lb. to the square inch having been recorded.

After determining on the location to be consolidated, injection pipes are driven into the mass by means of a compressed air hammer and special driving tools and connections; generally pipes of 1in. diameter of high-tensile steel, fitted with driving points and perforated near the point, are used. These pipes are driven a short distance at a time, when a measured quantity of Chemical No. 1 (sodium silicate) is pumped through the pipe; this is repeated after each short drive. When the pipe has been driven to the full depth required and Chemical No. 1 has been injected at each drive, a measured quantity of Chemical No. 2 (calcium chloride) is injected in the same way at each short withdrawal of the pipe. When the pipe is withdrawn it is found that the two chemicals have united on meeting and have formed a silica gel, together with the free silicic acid generated combining with the loose silicious particles forming the same binding material as in a natural silicious sandstone. This binds the ground treated into a solid permanent mass, which is insoluble in water. It is important to note that both chemicals combine to form one solid, so that no residual water is left in the ground likely to cause settlement and disturbance, as has been proved to be the case when cement slurries are used. Generally the pressures for injection vary from 50 lb. to 150 lb. per square inch. The effect is instantaneous, for as soon as the chemicals meet they combine and solidify or petrify the ground so that it is possible to remove the timbering immediately the last injection is completed.

"THE ENGINEER"

FIG. 19—CHEMICAL PROCESS AS APPLIED TO SEWER DIVERSION TUNNEL

This process has also been found very useful in drying up brickwork or concrete walls, which under high water pressures may be leaking seriously. In such cases the water is forced back by pumping in the chemicals which, as stated before, go wherever water may travel, and the treatment reaches into the heart of the wall. This method is far superior to that of plastering or to cement grouting, as neither of these would be effective in the case of moderately wet or very wet walls. In plastering, a slight leakage of water may be stopped, but the effect is only on the surface, and affords very little resistance to pressure head. In cement grouting the cement is filtered out by the fine pores of the concrete or brickwork before it can penetrate into the body of the wall. In any event cement cannot be effective until the setting of the cement, so that when there is much leakage it is almost impossible to stop it by cement grouting.

---

* Read before the British Section, Société des Ingenieurs Civils de France on Tuesday, 24th October, 1933.

In this chemical consolidation process the equipment required consists of several strong tanks in which the chemicals are mixed with water to the required specific gravity. A pump is required for each chemical; the pumps draw their supply of solution from the tanks and discharge into mains leading to the impregnating pipes. The equipment is of a simple nature, the chief expense being the supply of chemicals.

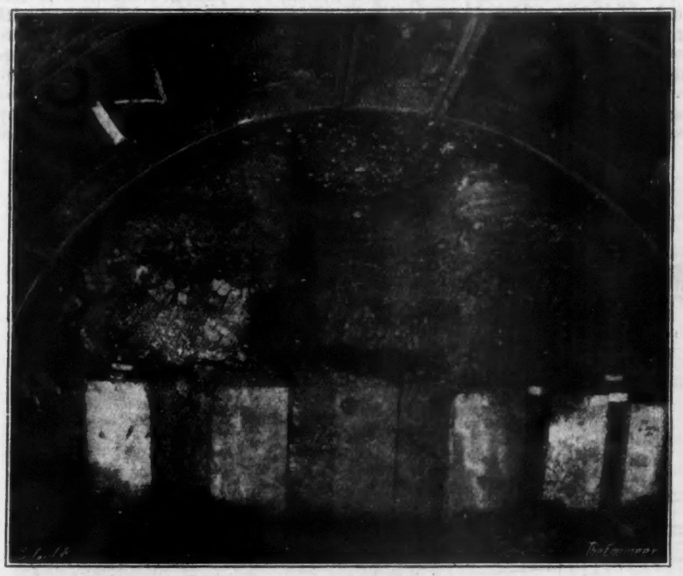

FIG. 21—SEWER DIVERSION TUNNEL AFTER CHEMICAL CONSOLIDATION

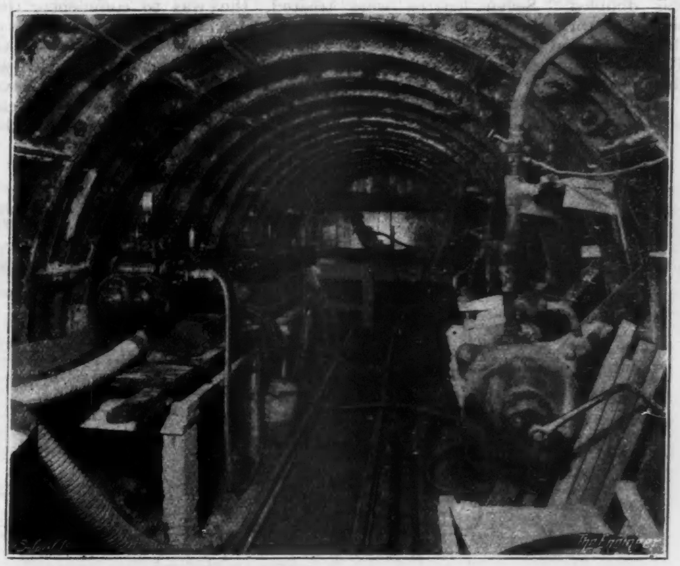

FIG. 22—PLANT AND PUMPS FOR CHEMICAL PROCESS

New applications of the process in engineering works are being developed continually, the process being proved invaluable in tunnelling unstable ground; in consolidating pile foundations which have been found to be settling, the carrying power has been greatly improved by solidifying the sandy soil around the base of the piles; retaining walls which have been in danger of collapse have had the ground behind them consolidated, resulting in safeguarding the structure; mine shafts have been made watertight, and the movement of abutments of bridges has been arrested. As time goes on it will be found that this system is a remedy which will become of more and more use to engineers.

The first application of this system in this country was in April, 1932, when John Mowlem and Co., Ltd., applied it to a trial length of the sewer diversion tunnel on the Bank–Monument Station contract, which they were carrying out for the Underground Electric Railways, under the direction of Messrs. Mott, Hay and Anderson, the consulting engineers in charge of the work. It was decided that a length of eleven rings, or 18ft. 4in., of the sewer diversion tunnel should be treated. The London blue clay was about 2ft. 6in. below the crown of the tunnel, and the ballast above the clay was of a very mixed and loose nature, requiring very careful and laborious tunnelling methods—see Fig. 18. This entailed close poling, packing with straw litter, pugging and grouting. Only very small widths could be exposed at a time, and, according to the modern practice, where polings have to be left in the ground behind the tunnel lining, steel instead of wooden polings were built in over each length of excavation. When an auger was drilled through the face boards, the sand and gravel were so loose that they poured through like an hour-glass; they had no cohesion and were practically dry. The original intention had been to put compressed air on this section, but it would have been impossible to hold the air, and as there was practically no water to be dealt with, no advantage was to be gained from it.

The scheme adopted on the trial length was to form an arch of chemically consolidated ballast about 2ft. thick over the crown of the tunnel. As shown on Fig. 19, this was carried out by driving injection pipes in the direction of tunnelling and radially from the axis of the tunnel. The pipes were passed through holes augered in the face boards at about 20in. centres, and were driven one at a time into the ballast by means of a compressed air hammer and special driving tools and connections. The pressures used for injection were from three to ten atmospheres. The estimated range of action was taken as being 1ft. around the pipes, which was proved in practice to be about right as a safe minimum. In order to cover eleven rings a second row of pipes was driven, as shown, inside the first row, which covered only six rings.

After treatment the ground was found to have been chemically solidified into a hard arch over the tunnel, and was also hardened in the face. It was possible to work with an open face, with occasional boards in the crown as a precaution and a relief to the dead weight of ballast above the solidified arch. These boards were removed as the rings were built so that no timbering was left in the ground—see Photographs 20 and 21. Trial holes were pricked in the consolidated arch, and the extent of the treatment was found to be from 12in. to 18in. above the line of the pipes.

Where the gravel was originally loose and sand absent, the white substance (the resultant of the combination of the chemicals) appeared and filled the voids, and where the face was made up of well-graded ballast a hard conglomerate was formed, and the binding material was almost invisible. Beds of sand were found to be solidified into a form of synthetic sandstone, and the thin layers of clay and loam met with were found to have adhered to the consolidated ballast. The roof arch was very hard, and where it came within the digging line the conglomerate required breaking out with small air hammers. Although hard, it was possible to trim the underside of the arch of hardened ground evenly to the digging line. The ground below the arch, which had been solidified, could be broken out with a pick.

FIG. 23—CHEMICAL PROCESS AS APPLIED TO 26-FOOT TUNNEL AT MONUMENT STATION

As the treatment of the trial length of eleven rings proved satisfactory, an order was placed with Siemens-Schuckert (Great Britain), Ltd., to carry out treatment for the remaining forty rings of the sewer diversion tunnel. It was decided to drive one fan of pipes at a time for a sufficient distance to cover six rings, the chemical work being carried out by a specialist foreman, while the men in the tunnel face drove the pipes. It required twenty-four hours to treat a length of six rings, and excavation was commenced immediately the treatment was finished. One ring could be excavated and completed in one-third of the time taken in the untreated ground, and the general rate of progress of the tunnelling was doubled. Seven lengths were treated, the chemical work being commenced at whatever time the excavation of each six rings was completed. The plant and pumps required for this work are shown in Fig. 22.

FIG. 24—CHEMICAL PROCESS AS APPLIED TO 26-FOOT TUNNEL AT MONUMENT STATION

As the results of the application of the chemical process had proved so satisfactory, the contractors, John Mowlem and Co., Ltd., arranged with Siemens-Schuckert (Great Britain), Ltd., for the joint rights of carrying out the process in Great Britain, which were ultimately transferred to Messrs. Edmund Nuttall, Sons and Co., and John Mowlem and Co. (Joint), Ltd. All the remaining work was carried out direct by Messrs. Edmund Nuttall, Sons and Co., and John Mowlem and Co. (Joint), Ltd.

At the junction of the inclined escalator tunnel with the horizontal machinery chamber tunnel, it was decided to consolidate a block of ballast to prevent the danger of a run of ground when the top of the inclined tunnel, which was driven uphill, entered the ballast. Pipes were driven from the disused sewer in two layers at 1ft. 9in. centres, the pumps being fitted up inside the sewer from which the injections were made. When the excavation for the tunnel penetrated above the clay level, a hard block of chemically consolidated ballast was found, and as there had been a small depth of water flowing on the clay at this point, the solidification of the ground added greatly to the safety of the excavation, which would otherwise have been a delicate matter owing to the presence of water in the ballast.

FIG. 25—CHEMICAL PROCESS AS APPLIED TO 26-FOOT TUNNEL AT MONUMENT STATION

For the chemical treatment of the 26ft. tunnel for the Monument Station, advantage was taken of the existence of the disused sewer for the first portion of the treatment. As shown on Fig. 23, a chemically consolidated arch was formed over the roof of this tunnel by driving pipes across the future tunnel and making two to three injections at the requisite distance of penetration. Pipes were driven one above the other in a vertical plane as shown. These "circles" of pipes were placed at 1ft. 9in. centres, and later widened to 2ft. centres. Careful supervision of the setting and driving of the pipes was needed to ensure that the solidification took place where required. Work was carried on day and night until a length of twelve rings from ring No. 18 to ring No. 29 had been treated. At each side of the break up for rings Nos. 20 to 21, where tunnelling was to commence, the ground was also solidified from the sewer to the digging line. Excavation was then commenced in the break up while chemical treatment proceeded as before to cover rings Nos. 17 to 11. This excavation was carried out boldly and rapidly, and open poling was used instead of the laborious methods necessary in loose ground, even when compressed air is employed—see Fig. 27.

The ballast was solidified uniformly and evenly in spite of dirty patches, possibly due to leakages from the old sewer, which was 100 years old. The modern practice of close poling with steel plates where timbering cannot be removed was not required, and a considerable saving effected, no timbering being built into the ground—see Fig. 28. The solidification was carried out from the old sewer to cover rings Nos. 11 to 29, so that a sufficient number of rings could be built under this protection to form a good-sized working chamber.

The plant was then transferred from the sewer to a hanging stage in the 26ft. chamber. The remaining treatment was carried out from inside the 26ft. tunnel by driving a fan of pipes into the face, as shown on cross section D D on Figs. 24 and 26, and forming a hood of consolidated ballast as in the case of the sewer diversion. Excavation proceeded in one face, while treatment was carried on at the other. When rings Nos. 16 to 12 had been built, excavation was carried on from rings Nos. 29 to 34, while the ground was treated from rings Nos. 11 to 5. This alternation was carried on until the tunnel and headwalls were completed. The final length of the headwall was treated from the old sewer, as the masonry of a dummy shaft of the old sewer, as shown on Fig. 25, interfered with treatment from the face. Tunnelling around this dummy shaft had to be carried out with caution, owing to the number of headings and passages already existing.

FIG. 26—CHEMICAL PROCESS AS APPLIED TO 26-FOOT TUNNEL AT MONUMENT STATION

As shown on Fig. 25, the concrete foundations of the Guardian Assurance building were 8ft. above the London clay, close up against the site of the 15ft. passage. The main length was done by ordinary underpinning, which became very costly, owing to the divergence of the 15ft. passage from the Guardian frontage. These foundations were underpinned with concrete and blue brickwork in the usual way, until a point was reached in which the line of the passage had diverged from the line of the foundations sufficiently far to make further underpinning unnecessary. In order to minimise the danger of any draw in the ballast when excavating for the cast iron lined tunnel, it was, however, decided that a protecting wall of consolidated ground should be formed along the frontage line. Fifteen pipes of 30ft. penetration were driven horizontally through the face boards and injected, while a return wall was formed at the end of the concrete underpinning by driving and injecting twenty-two pipes of about 12ft. penetration, working from the clay upwards. When excavation was carried out, the ballast, as shown in Fig. 30, was found to be chemically solidified from the clay tight up to the concrete, as no perceptible junction was visible between the concrete foundations and the solidified gravel. A sample of ballast from under the Guardian office contained 24 per cent. of dirt and silty matter. This sample was solidified in a cylindrical mould 4in. diameter and 6in. long, and crushed at Mr. R. H. Harry Stanger's laboratory within 35 minutes of solidification, and a crushing strength of 15 tons per square foot was obtained.

The 15ft. internal diameter tunnel was constructed after the 26ft. machinery chamber, and tunnelling was carried out from the flat-roofed chamber. Advantage was taken of the old sewer to drive injection pipes radially from the sewer, and at 2ft. intervals to form an arch over the future tunnel, as shown on section E E of Fig. 25. The chemical work was performed ahead of the tunnelling, which was carried on continuously.

This work, being the pioneer work in this country, has been described in somewhat minute detail, so that it may be clear how this interesting process can be employed in the most difficult situations.

Another interesting example of the use of this process in this country was carried out at Knightsbridge (East) Station, where Sir Harley H. Dalrymple-Hay, M. Inst. C.E., the consulting engineer for this work, employed the chemical process in the construction of the escalator tunnel, which was being constructed by Mitchell Brothers, Sons and Co., Ltd., for the Underground Electric Railways. The internal diameter of the cast iron lining of this tunnel was 23ft. 2½in., and there was only 2ft. 6in. of cover between the road surface and the top of the upper chamber.

The tunnel was to be driven at 30 deg. through yellow loamy sand with bands of clay into sand and small ballast with coarse ballast below, until London clay was reached, at a depth of 40ft. below the street. There was 8ft. of water lying on the clay, being considerably more than was found in the construction of the original station twenty-five years previously.

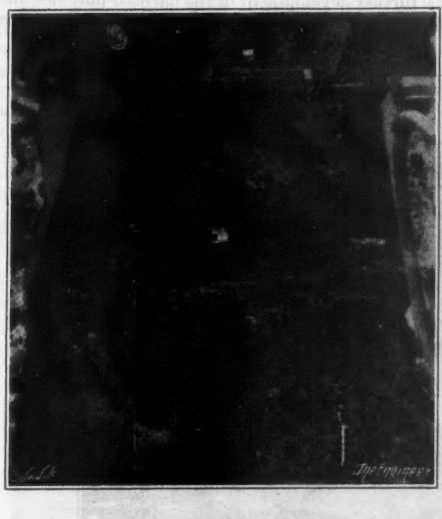

FIG. 27—EXCAVATION FOR BREAK-UP 26-FOOT TUNNEL AFTER CHEMICAL TREATMENT

Owing to the nature of the ground and the close proximity to buildings, roads and pipe services, the original scheme was to make use of a hooded shield and drive this tunnel under compressed air. However, after having had proof of the effectiveness of the chemical process, Sir Harley H. Dalrymple-Hay designed an alternative scheme of an original nature. This scheme is shown on Fig. 29, and consisted of first driving 4in. external diameter boring tubes into the clay at 1ft. centres over the crown of the future tunnel, and then driving injection pipes parallel to these and forming an arch of chemically consolidated ground around the 4in. diameter tubes The purpose of the 4in. tubes was two-fold. Firstly, they were to form a system of reinforcing bars in order to make perfectly sure that the weight of the ground would be safely carried by the chemical consolidation; and, secondly, in the event of any possible weak place these tubular bars could be used to support cross polings.

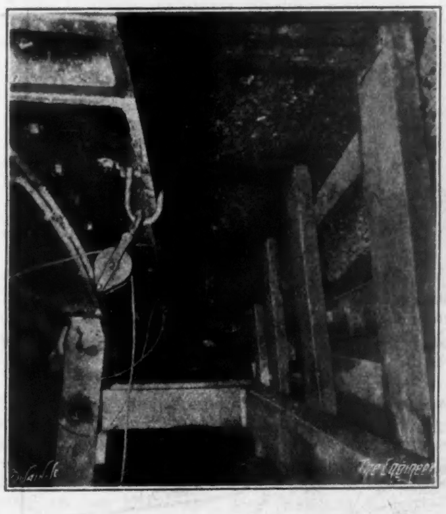

FIG. 28—EXCAVATION AFTER CHEMICAL INJECTION FOR LEADING RING OF 26-FOOT TUNNEL

Edmund Nuttall, Sons and Co. and John Mowlem and Co. (Joint), Ltd., carried out the chemical work and the boring from a 27ft. diameter semi-circular chamber, which was built above water level. The pipes were driven parallel to the 30 deg. tunnel, the maximum length of driving of any pipe being 40ft. In all, 1330ft. of the boring tubes were driven and augered out in three weeks by means of specially designed appliances. They proved to be perfectly true and straight for the whole length. The chemical pipes were then driven and treatment carried out in three more weeks, practically cutting off all water from the works.

Compressed air was then used as originally intended, and it was found that the amount of air required was greatly reduced, compared with the amount used for the small 8ft. pilot tunnel, and a very considerable saving in time and money compared with the shield method previously contemplated.

FIG. 29—KNIGHTSBRIDGE EAST STATION, CONSOLIDATED GROUND OVER ESCALATOR TUNNEL

The loamy sand was found to have been successfully hardened in spite of the presence of bands of yellow clay, while the ballast was consolidated up to the pilot tunnel, and was very successfully treated, although this was done in 8ft. of standing water at the end of a 40ft. drive of pipe.

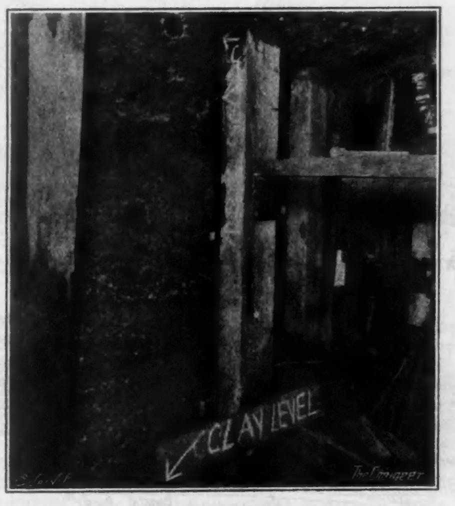

FIG. 30—EXCAVATION FOR UNDERPINNING GUARDIAN BUILDING AFTER CHEMICAL TREATMENT

Other chemically consolidated works carried out in this country include:—

Stoppage of leaks in concrete walls at the Ford Motor Company's power-house at Dagenham. Consulting engineer, Sir Cyril Kirkpatrick and Partners.

Consolidation of ballast in 8ft. of water in order to support the weight of the proposed shield at Knightsbridge (East) Station. Consulting engineer, Sir Harley H. Dalrymple-Hay, M. Inst. C.E.

Chemical injection behind clutches of "Simplex" steel sheet-piled dam to prevent water leakage at Knightsbridge (West) Station. Consulting engineer, Sir Harley H. Dalrymple-Hay, M. Inst. C.E.

Consolidation of ballast over 22ft. 9in. escalator tunnel for John Cochrane and Sons, Ltd., at Chancery-lane Station to make the ground secure and prevent air loss. Consulting Engineers, Messrs. Mott, Hay and Anderson.

Underpinning to a party wall at the new R.I.B.A. Building, Portland-place, by consolidating the ballast from the footings to the London clay through 7ft. of water. Consulting engineers, Messrs. R. T. James and Partners.

Many applications of this chemical process have been made on the Continent, and the following give an idea of the range of applications:—

For supporting the ground at the end of existing bridge piers during widening of the Jannowitz Bridge, Berlin.

Forming a wall of solidified sand from 60ft. to 90ft. below ground level to protect the existing piers of the Monbijou Bridge while a caisson was being sunk close to it, and 30ft. deeper at the University Eye Hospital, Berlin.

For closing the end of a trench sheeted with steel piling. Large pipes passing through the end of the trench prevented closing by steel piles, and the ballast was solidified round the pipes, at the Ankelmannplatz, Hamburg.

For prevention of leakage through the walls of graving docks at Kiel and Wilhelmshaven.

For prevention of leakage in dams and weir walls at Yngeredsfors, Sweden, and Grodek, in Poland.

For solidifying the ground between a timbered excavation and existing buildings. The buildings were settling owing to loss of ground during excavation. A row of pipes were driven and injected between the side of the pit and the buildings, and movement was arrested, in Hamburg.

The author is indebted to Mr. H. J. B. Harding, of Edmund Nuttall, Sons and Co. and John Mowlem and Co. (Joint), Ltd., and to Mr. H. C. Wehe, of Siemens-Schuckert (Great Britain), Ltd., for their collaboration in preparing this paper; and also to Mr. F. E. Wentworth-Sheilds, Sir John Wolfe Barry and Partners, Messrs. Mott, Hay and Anderson, and Sir Harley H. Dalrymple-Hay, for their kind permission to give details and photographs of the work being done under their direction.

THE CHARTERED INSTITUTE OF PATENT AGENTS.—The annual dinner of the Chartered Institute of Patent Agents took place on Tuesday evening, October 31st, at the Hotel Victoria, when a large company of members, guests, and ladies was present and took part in the dance which followed the dinner. The chair was taken by the President, Mr. G. Melville Clark, and the toast of "The Chartered Institute of Patent Agents" was fittingly proposed by Dr. M. F. Lindley, the Comptroller-General of Patents, Designs and Trade Marks. In his speech, Dr. Lindley referred to the happy relations which existed between the Institute and the Patent Office, and called attention to the forthcoming meetings in London in May, 1935, of the International Union for the Protection of Industrial Property, which would consider the international sides of the question. The new Designs and Patents Act had been in operation for close upon a year, with very satisfactory results, and he looked forward to the early completion of the work for a new Trade Marks Act. The President briefly responded to this toast. In proposing the toast of "Our Guests," Mr. C. E. Every-Clayton referred to the excellent work which Sir William Jarratt, late Comptroller-General, was doing as Secretary of the Patents and Designs Federation, and he also complimented Mr. Justice Sir Fairfax Luxmore on his work on the Patent Appeal Tribunal. In responding to this toast Sir Fairfax Luxmore spoke of the help given to him by the members of the Institute. In supporting the toast, Mr. Alan E. L. Chorlton, President of the Institution of Mechanical Engineers, stressed the importance in national life of the engineer and the value to industry of invention. He said that he was sure that the Institute always did and would always do its best to help the engineer inventor, and he referred to the efforts towards that end which were being made by a committee of the Institution of Mechanical Engineers.

Haifa Harbour.

THE harbour works at Haifa on the coast of Palestine, the construction of which was begun in 1929 by the Government of the Mandated Territory, were formally inaugurated by the High Commissioner for Palestine, Lieut.-General Sir Arthur Wauchope, on Tuesday, October 31st. We published in our issue of July 1st, 1932. a short account of the works then in progress, and we are now able to supplement it by a more detailed description. Herewith and on page 432 will be found a series of views of the harbour, some of which show the works in their completed state. As far back as 1922 the Crown Agents for the Colonies commissioned Mr.—now Sir—Frederick Palmer, K.C.M.G., to report on the question of the construction of a harbour for Palestine, which has a coast line of about 150 miles. The surveys and investigations made under his direction definitely indicated Haifa as the most suitable site for a harbour in preference to any other of the sites that had been suggested, including Jaffa. Mr. Palmer's report was made in 1923, but it was not until June, 1927, that his recommendations to construct a harbour at Haifa, at an estimated cost of £1,000,000, was adopted, and Messrs. Rendel, Palmer and Tritton were appointed consulting engineers for the work. The plans prepared, after a detailed survey of the site and borings had been made, included works estimated to cost 1½ million pounds. In February, 1929, it was decided to construct the harbour works by direct administration under the supervision of the engineers, and the Haifa Harbour Works Department was organised for that purpose. Preliminary work was begun in April, 1929, and the first train load of stone from the quarries, which had, in the meantime, been opened out at Athlit, on the sea coast some 10 miles south of Haifa, was dispatched to the harbour in October of that year.

FIG. 1—MAP OF HAIFA AND SURROUNDING COUNTRY

The town of Haifa is situated on the southern shore of the Bay of Acre—plan, Fig. 1—and the roadstead, in which vessels lay at anchor before the construction of the harbour works, was well protected from the south and south-west by Mount Carmel, the western extremity of which rises rapidly to a height of nearly 1000ft. The northern slope of the mountain falls more gradually towards the bay, and on it stands the town with the railway skirting the shores.

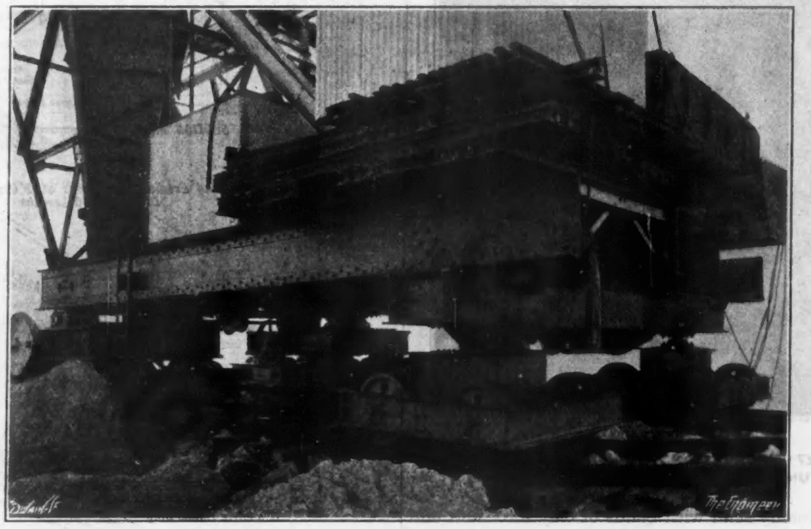

FIG. 3—CRANE ON MAIN BREAKWATER AFTER STORM OF JANUARY, 1931

TRADE OF HAIFA.

Haifa is the only harbour on the Palestinian coast, and in the past the absence of harbour facilities has been one of the hindrances to the development of the shipping trade of the country. At Jaffa, which, from the days before the rise of the Roman Empire, has been regarded as the port of Jerusalem, vessels still have to lie in the open roadstead, and both goods and passengers are conveyed to and from the shore in lighters and boats. Haifa is the headquarters of the Palestine Railways, and, since the British mandate, has developed into a busy industrial town. The terminal at Haifa of one branch of the Iraq oil pipe line is now assured, and is expected to have a capacity of 2,000,000 tons annually. A site for an oil dock was provided for when designing the harbour, at the south-east end under the shelter of the lee breakwater, and work on it and on the east reclamation, which will be made concurrently with the oil dock, has begun. A concession for the abstraction of salts from the Dead Sea is now being developed, mainly with capital from Jewish sources, and an annual export through Haifa of 100,000 tons of potash is expected. The fruit trade of Palestine is growing rapidly, the Jaffa orange being one of the principal exports of the country at the present time. Estimates based on the acreage of orange groves, which have or are being planted, show a possible development from the present maximum annual export from Palestine of four million cases to over nine million cases within ten years. The major part of this increase might have to be dealt with at Haifa, and, should such estimates be realised, some further development of the harbour may become necessary within a short time. Provision has been made for the development of the western part of the harbour within the breakwaters by the construction of additional quayage, as shown on the plan—Fig. 2.

FIG. 2—PLAN OF HAIFA HARBOUR, 1933

BREAKWATERS.

The sheltered area of the new harbour is protected by two breakwaters—Fig. 2—the more important, known as the main breakwater, is about 1¼ miles long and is thrown out in an easterly direction from the shore near Ras-el-Kerum, the northern extremity of the Carmel headland. The breakwater is roughly parallel with the town frontage. The second, or lee breakwater, forms a seaward prolongation of the previously existing railway jetty at the east end of the town. It is about half a mile long and runs out in a northerly direction. The tidal rise at Haifa is insignificant, rarely exceeding 1ft., with a maximum range of about 3ft. The maximum exposure of the works is from about north-west on a line oblique to the face of the main breakwater. The lee breakwater and the inner works of the harbour are, therefore, well sheltered from storms. The sea bed over the harbour area is for the most part compact firm sand, forming an excellent foundation for the rubble mounds which constitute the breakwater and the rubble base for the quay walls.

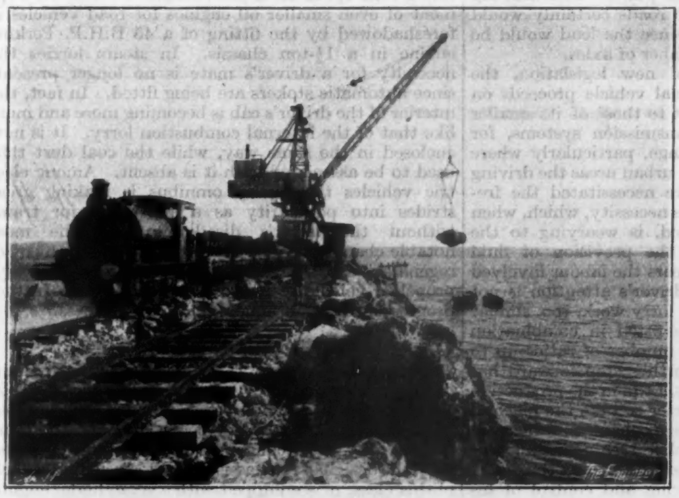

FIG. 4—MAIN BREAKWATER AND CRANE—JANUARY, 1931

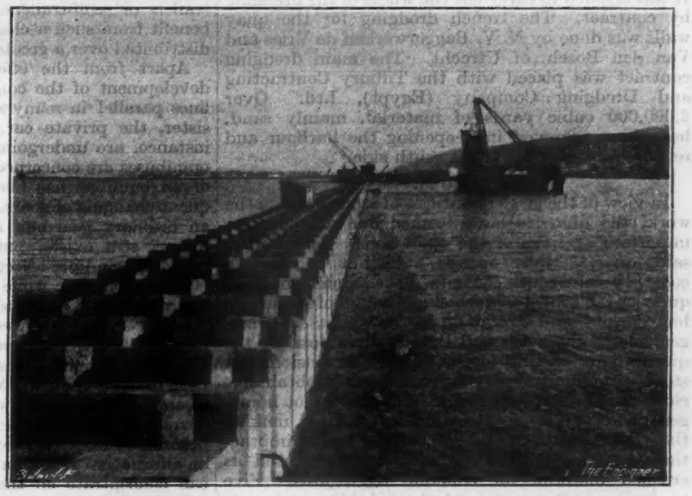

FIG. 5—SLICED BLOCK WORK IN MAIN QUAY WALL—JANUARY, 1932

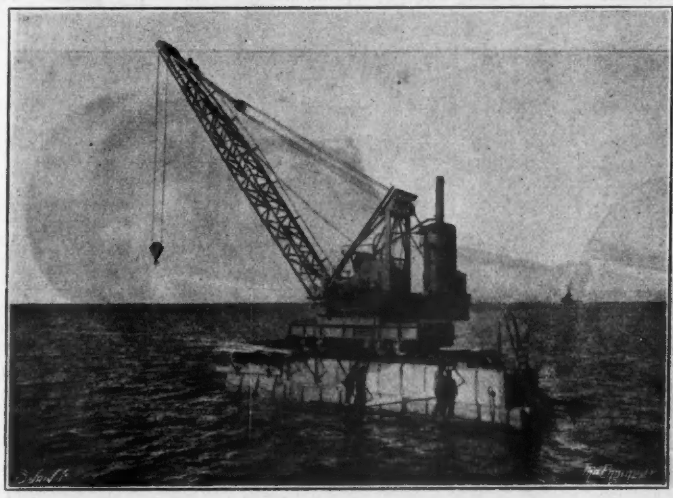

FIG. 6—MAIN QUAY WALL AND BLOCK-SETTING CRANE—SEPTEMBER, 1931

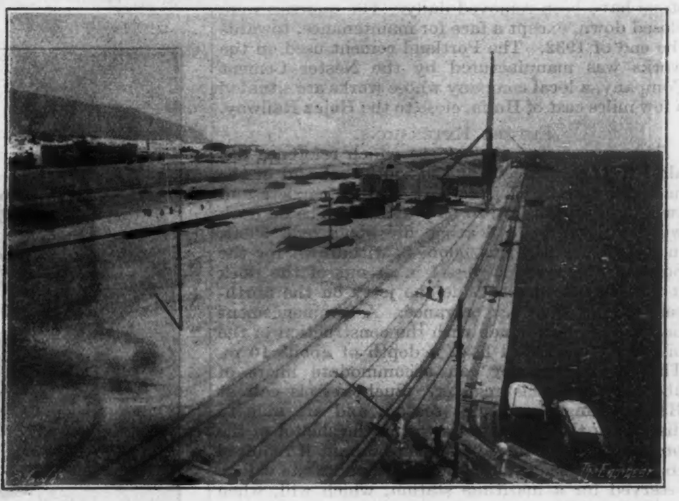

FIG. 7—DEEP-WATER QUAY AND RECLAIMED AREA—AUGUST, 1933

MAIN BREAKWATER.

The main breakwater constitutes the largest item of cost in the works; it is formed of natural blocks of quarried stone, graded according to size, the larger stones up to 15 tons weight being placed on the seaward face. The core or hearting material of the breakwater is of small stones from the quarries ranging in size from a few pounds each up to 1 cwt. The structure has a width of about 23 m. at mean sea level, and the upper part of the rubble mound has a slope on the sea face of 1 in 4. The settlement of the rubble in the sand of the sea bed has, it is believed, been relatively small. The head of the breakwater is situated close to the 12 m. contour and the average depth of water on the site of the breakwater mound is between 8 m. and 9 m. Throughout its entire length the breakwater is constructed with a concrete capping and parapet laid *in situ*, the top of the parapet being 4 m. above datum (mean sea level at Haifa). Views of the concrete work are shown in Figs. 8 and 9, page 432; both show the breakwater looking towards the inner or west end. At intervals of about 33 m. along the middle portion of the breakwater are set heavy cast steel mooring bollards—see plan, Fig. 2—one of which is seen in Fig. 8. These are bedded in masses of concrete keyed into the rubble mound. Some of these bollards are designed to take a pull of 200 tons and others of 150 tons. The mooring system adopted at Haifa provides for stem-on mooring of ships to the breakwater bollards, vessels dropping their head anchors when berthing. The general arrangement of the moorings is indicated in the plan —Fig. 2. The main breakwater contains about 1,100,000 cubic yards of stone rubble; the maximum quantity deposited in one month being 69,000 cubic yards. The stone, all of which came from Athlit, is a sandstone of medium hardness, which is capable of being quarried in large masses. All of it was hauled from Athlit over the Palestine Railways. Some of the stone of the smaller grades, forming the core of the breakwater mound, was deposited from hopper barges up to a level which would permit of discharge by this means. The remainder was placed in position by a specially designed pillar crane —Figs. 3 and 4—capable of handling a load of 15 tons at a radius of 65ft. All but the largest stones were tipped from steel tray skips (seen in Fig. 4). The crane ran on two 4ft. 8½in. gauge tracks connected to the service tracks for the trains of stone trucks. All the tipping in advance of the formation level was done "end-on" by the crane, no staging being used. The crane was supported on six bogie trucks very fully articulated to provide for inequalities of level in the rail tracks. The details of the crane carriage can be seen in the view, Fig. 3, showing the bogies and twisted rails after a very heavy storm in January, 1931. This storm is said to have been the most severe experienced at Haifa for over thirty years, but caused no damage to the permanent works, even in their unfinished state.

The whole of the concrete capping and parapet of the breakwater was constructed on the return journey of the temporary crane and as the wagon rails were lifted. The side walls of the capping serving as shuttering are of rough random sandstone masonry set in cement mortar and built in so as to fill the voids between the underlying masses of large stone. Timber shuttering was used only for the concrete coping. The stunt ends of sections of the mass concrete were also built up of rough masonry. This method of construction was found to be both more suitable and more economical than fitted forms. The concrete was gauged and mixed on a lighter, seen in Fig. 9, moored alongside the breakwater, the mixed concrete being placed in position in the breakwater by a transporter, also mounted on the lighter. The cement, aggregates, and water were brought to this floating concrete plant from the shore by supply lighters. The concrete aggregates used were crushed limestone from a privately owned quarry in Mount Carmel, and sand from the foreshore at Athlit.

LEE BREAKWATER.

The lee breakwater, which, as we have already said, is formed by prolonging the old railway jetty, contains about 230,000 cubic yards of stone. It is of less massive section than the main breakwater, its top width being only 5 m. The outer slope of the mound is 2 in 3 and the harbour slope 3 in 4. The commencement of the construction of the lee breakwater was retarded in order that it should have the protection of the main breakwater during the winter storms. Two views of the completed breakwater are shown in Figs. 10 and 11. The first, a view looking north, shows the main breakwater in the distance, and the second, looking to the south, the breakwater head and light. The lee breakwater was provided with bollards, similar to those on the main breakwater, for temporary use as "stem-on" moorings, pending the decision, now taken, to construct the oil dock under its shelter. The method of construction adopted for the lee breakwater was the same as for the main breakwater and the plant employed was of similar character, except that the crane used on the former was of 12 tons capacity and the stone rubble used in facing the slopes is in general of smaller dimensions than in the main structure.

QUAYS.

On the landward side of the water space enclosed by the breakwaters an area of land has been reclaimed, along the outer edge of which quays have been constructed for the accommodation of cargo steamers and lighters. The deep-water quay, or main wharf, about 1400ft. long, provides accommodation for three or four steamers. An extension of this quay towards the south-east and east provides quayage, 800ft. long, for lighters, the depth of water in the berths varying from 9·4 m. to about 5 m. The steamer berths in front of the deep-water quay are dredged to 9·4 m. below mean sea level. The quay walls are constructed of concrete blocks, generally 5 to 7 tons in weight, capped with mass concrete. For the most part the block work has been set on the slicework principle, and a view of the main quay, in course of construction, is shown in Fig. 5. The block work is founded at a level of 10 m. below mean sea level on a rubble base, which has a minimum thickness of 1 m. The rubble base was deposited from hopper barges in a trench dredged in the sea bed, consisting of sand, clay, and some conglomerate. The construction of the quay walls was begun at a central abutment of horizontal coursed blocks, from which the sliced work was continued in both directions by two 8-ton cranes travelling on the wall itself. A view of the central abutment and the first crane in course of erection is reproduced in Fig. 6. Horizontal block work was also employed for the western terminal of the quay wall and at the angle in the lighter quay. All the quay walls are backed by stone rubble placed in position before the sand filling was deposited.

RECLAMATION.

Where the reclaimed area is not bounded on the harbour side by quay walls, it is retained by rubble stone dykes. Both the western and the eastern dykes have been completed (see plan, Fig. 2), and about 90,000 cubic yards of stone was used in their construction. The material for the reclamation has been dredged from the deep-water area formed between the breakwaters, the land so reclaimed being about 91 acres. The sand filling was pumped ashore at suitable points or on the quay walls and dykes, and is forming an excellent and firm foundation for roads and buildings.

TRANSIT SHEDS, &c.

Two single-storey steel-framed transit sheds, supported on piled foundations, have been built behind the deep-water quay. One is so constructed as to permit of the addition of a second storey if this should be found necessary for the orange traffic. The walls of the transit sheds, as well as some of the other buildings erected in connection with the harbour, are constructed of Winget concrete blocks made on the site. The doors of the sheds, are steel-framed, filled in with reinforced concrete panels. The general arrangement of the road and railway facilities on the quays and reclaimed area will be clear by reference to the plan, Fig. 2; and a view of the deep-water quay is reproduced in Fig. 7.

DREDGING.

In the initial stage of the harbour development, now completed, about 175 acres have been dredged; about 100 acres to a depth of 11·3 m. below mean sea level, and the balance to 9·4 m. or over. It was decided to carry out the whole of the dredging by contract. The trench dredging for the quay walls was done by N. V. Baggerwerken de Vries and Van den Bosch, of Utrecht. The main dredging contract was placed with the Tilbury Contracting and Dredging Company (Egypt), Ltd. Over 2,000,000 cubic yards of material, mainly sand, have been removed in deepening the harbour and reclaiming the areas on its south side.

QUARRIES.

In view of the large quantities of stone used on the work, the quarries have formed one of the most important sections of the operations. As we have said, quarries were opened at Athlit on the sea coast, 10 miles south of Haifa. The stone from these quarries is a sandstone, which, although of somewhat low density and not of great hardness, is homogeneous in character and thus renders possible the quarrying of natural blocks of large dimensions. A stone of greater density and hardness is obtainable close to the site of the works, but this is not homogeneous, and is laminated and much fissured, making the quarrying of blocks of sufficient size impracticable. This hard stone was, however, used as crushed material for concrete aggregates. Five quarrying units were worked at Athlit, each unit comprising one 15-ton derrick crane and two 5-ton travelling cranes. Quantities up to 5000 tons of stone have been removed daily. The quarries were closed down, except a face for maintenance, towards the end of 1932. The Portland cement used on the works was manufactured by the Nester Cement Company, a local company whose works are situated a few miles east of Haifa, close to the Hejaz Railway.

FUTURE EXTENSIONS.

The site of the oil dock, to which reference has already been made, is at the south-east end of the harbour. Berthing jetties for two oil carriers and two lay-by berths are to be provided. The oil dock will be closed by a floating fire boom over 300ft. in length. When this boom is withdrawn for the purpose of passing a vessel in or out of the dock it will be placed alongside the jetty on the north-east side of the dock entrance. A commencement has already been made with the construction of the oil dock, which will have a depth of about 10 m. The harbour proper can accommodate liners of about 30,000 tons register. Such vessels call at Haifa during the tourist season, and are able to disembark their passengers within the shelter of the breakwaters. A liner berth can be built if required to enable passengers to land direct, and a site will be reserved for a maritime station, which will, when built, in addition to serving local requirements, act as the terminal for the proposed Haifa–Baghdad Railway, should the latter be constructed.

The area of sheltered water inside the breakwaters is approximately 300 acres, but will be reduced to about 250 acres when the reclamation at the western end of the harbour and the future extensions of quays have been carried out. The plan, Fig. 2, shows the position of the future line of quays and transit sheds. The total expenditure on the harbour works of about 1¼ millions includes all the works which are shown in the plan of the harbour, with the exception of the future reclamation; the oil dock and its accessories, and the east reclamation now in progress. The post office, general office, and Customs house, which, except for the foundations, were built under the direction of the Palestine Public Works Department, are covered by the expenditure of 1¼ millions.

We are indebted to Messrs. Rendel, Palmer and Tritton for the use of plans and photographs and for information which has enabled us to prepare this description of the harbour works.

MANCHESTER ASSOCIATION OF ENGINEERS.—At the opening meeting of the session the Constantine Medal for the best paper read during the preceding session was awarded to Mr. S. N. Brayshaw, M.I. Mech. E., for his contribution on "The Design and Operation of Industrial Furnaces." The Butterworth Medal for the best contribution to the discussions was awarded to Mr. C. H. Painer.

Commercial Motor Transport Exhibition.

No. I.

THERE are definite indications at the Commercial Motor Transport Exhibition, which opened yesterday at Olympia, London, that recent legislation with regard to the taxation of heavy lorries will have repercussions on design. Many makers are seriously putting in hand experiments with the object of reducing chassis weight so that a greater paying load can be carried without exceeding the maximum legal gross load for the vehicle concerned. Since the new taxation is based upon tare weight, a twofold advantage is gained if the chassis weight can be reduced. As yet there has hardly been time for any notable modifications of chassis design to be observable, but the next biennial exhibition should be of great interest from this point of view. The results of legislation are not always those expected by its originators, and it is by no means impossible that, as one firm of trailer builders suggests, the trend of progress may be towards the evolution of light power units drawing trailers or semi-trailers. The roads certainly would benefit from such a change, since the load would be distributed over a greater number of axles.

Apart from the effects of new legislation, the development of the commercial vehicle proceeds on lines parallel in many respect to those of its smaller sister, the private car. Transmission systems, for instance, are undergoing change, particularly where omnibuses are concerned. In urban areas the driving of an omnibus has heretofore necessitated the frequent changing of gears. This necessity, which, when an ordinary gear-box is fitted, is wearying to the driver, still exists, but by the provision of fluid fly-wheels and pre-selecting gears the labour involved is much reduced, while the driver's attention is not distracted from the road. In lorry work, too, similar "labour-saving" devices are fitted in combination frequently with an increased number of ratios up to six or even eight. A still further step forward has been taken by Leyland Motors, Ltd., in the production of an hydraulic torque converter to take the place of gears altogether. When this mechanism, which we described in our issue of October 13th, is installed as an alternative to the conventional gear-box the driver can concentrate on the steering and control of his vehicle undistracted by the possibility that a change of gear may be necessary. Anything like these various improved transmission systems that increases the ease with which a driver can control his vehicle is quite obviously an important contribution to public safety—a matter of some concern in these days when the number of accidents mounts from year to year. In brake gear, another mechanism important for the same reason, there is a suggestion that the hydraulic system with its advantages of simplicity and automatic compensation, combined with high efficiency, is coming further into favour.

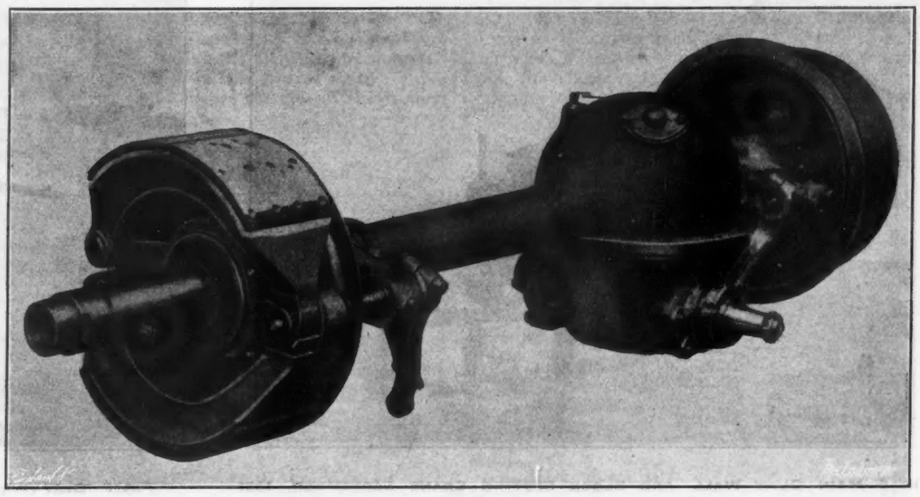

FIG. 1—REAR AXLE OF "HERA" LUXURY COACH—GILFORD

In commercial vehicles of all types, internal combustion, steam, and electric, much concern is now shown for the physical comfort of the driver. Not so many years ago he was only protected from wind and rain and snow by a low dashboard, but nowadays he is enclosed in a compartment approaching in comfort that of a closed private car. Warmed electrically, by the engine, or by the boiler, he is able to concentrate on the work in hand unaffected by the climatic conditions.

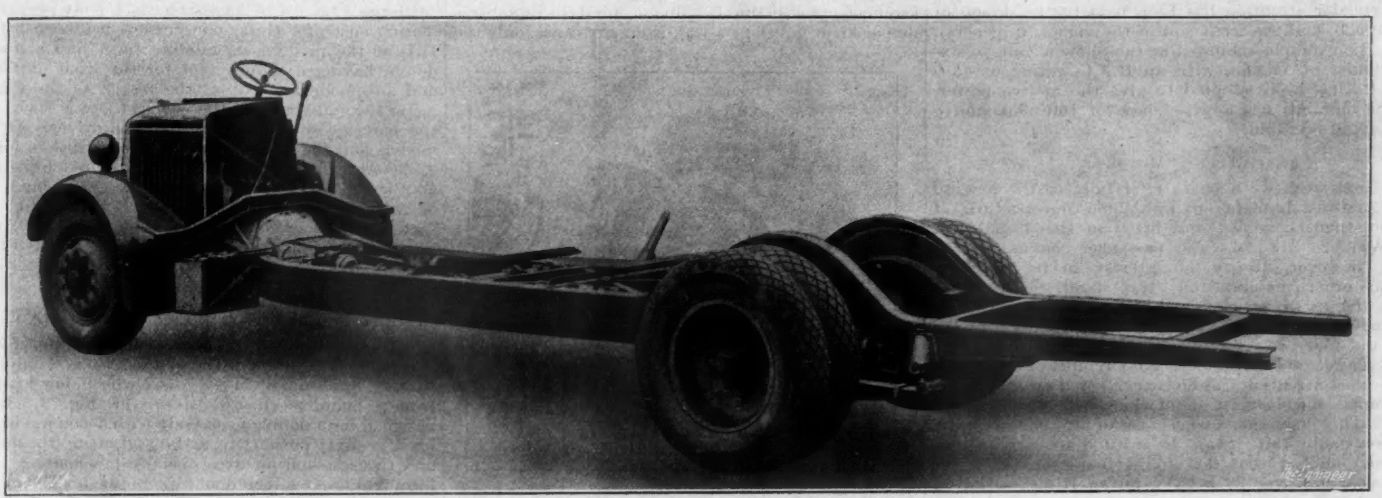
Just as the question of suspension is being studied for the ordinary car, so in lorries and omnibuses do novel arrangements appear from time to time. But no definite trend in any particular direction appears to be emerging similar to that which suggests that independent springing may be the thing of the future in private cars. Nor in the case of engines does there seem to be any great urge to place it elsewhere than at the front, although in coach design the Associated Equipment Company, Ltd., has already arranged the engine at the side of the vehicle beneath the seats, while in the new "Pug" 2-tonner, by Commer Motors, Ltd., it is placed behind the cab and beneath the body. Greater space for the paying load has been obtained by adopting "forward control" or by carrying the engine on cantilevers ahead of the front axle. But these arrangements were introduced some time ago and are by no means novel.

The steady development of the oil engine continues, and the old trouble known as "Diesel knock" seems to have been largely overcome as a result of careful design of cylinder heads and improvements in injection systems. Weight reduction, which has become of even greater importance as the result of recent legislation, is perhaps now the most pressing problem facing high-speed oil engine designers. The development of even smaller oil engines for road vehicles is foreshadowed by the fitting of a 45 B.H.P. Perkins engine in a 1½-ton chassis. In steam lorries the necessity for a driver's mate is no longer present, since automatic stokers are being fitted. In fact, the interior of the driver's cab is becoming more and more like that of the internal combustion lorry. It is now enclosed in the same way, while the coal dust that used to be associated with it is absent. Among electric vehicles the trolley omnibus is making great strides into popularity as a substitute for trams without the latter's disadvantages. The most notable change recently has been the development of regenerative braking equipment. But the battery-propelled vehicle seems to make little or no further progress into favour in new fields of usefulness.

GILFORD MOTOR COMPANY, LTD.

Except for the O.S. 4 3-ton chassis, the exhibits of the Gilford Motor Company, Ltd., of High Wycombe, are confined to omnibuses and coaches. The "Hera" super-luxury coach attracts attention, not only by the richness of its furnishing, but also from the design of its chassis—Fig. 2. As befits a vehicle of this class, it is equipped with a six-cylinder engine, capable of developing 118 H.P. at 2500 r.p.m. Its R.A.C. rating is 45 H.P., and it has a fuel consumption of approximately 8 miles per gallon. The arrangement of the cylinders is in two blocks of three each, and Ricardo heads and wet cylinder liners are fitted. The engine is mounted on a three-point suspension system. Careful consideration has been given to the design of the four-speed gear-box, and as a result a third gear ratio was chosen, such that the speed of 30 m.p.h. could be reached without unduly racing the engine. This gear is thus particularly useful in congested streets and the coach is able to maintain high average speeds in such neighbourhoods. The drive is taken to the rear wheels through fully floating axle shafts. The rear axle is of the underslung type, with the driving and differential gear offset to the near side. In the engraving reproduced in Fig. 1 the arrangement of this axle can be seen, and the width of brake shoe and large drum diameter can be observed. The triple servo braking system is employed, and the hand brake, operating on the rear wheels, actuates the same shoes as the foot brake through a specially designed compound lever to give lost motion. In the system of levers and rods between the master servo and the brakes themselves, ball bearings are used to support all rotating shafts. The length of the chassis is 27ft. 4½in. and its wheel base 17ft. 6in. The front and rear tracks are not identical, being 6ft. 3½in.

CHASSIS AT THE COMMERCIAL MOTOR TRANSPORT EXHIBITION, OLYMPIA



The Engineer

FIG. 4—SIX-TON LORRY CHASSIS—ALBION

and 5ft. 8¼in. respectively, and the overall width of the chassis is 7ft. 5½in. The turning circle is 58ft. 6in. in diameter and the weight of the complete chassis 3 tons 16 cwt.

In the "Zeus" 56-seater double-deck omnibus particular attention has been paid to the design of the cab, and the front end of the vehicle in general. In the example exhibited at the Show a Tangye six-cylinder oil engine, with an R.A.C. rating of 45·9 H.P., has been adopted to give the motive power. The omnibus has a wheel base of 16ft. 3in. and a track of 6ft. 1½in.

ALBION MOTORS.

Next week we hope to refer fully to the new oil engine just brought out by Albion Motors, Ltd., of Scotstoun, Glasgow, and fitted in the 35/85 H.P. "Valkyrie" 32/36-seater passenger chassis. There is, however, plenty of interest to be found in the other exhibits on the stand, particularly as there can be examined there a number of new models. Out of the total of eight vehicles on the stand four are entirely new models and three have never been shown previously at Olympia. Perhaps the greatest attention will be concentrated on the new 6-tonners, the chassis of one of which is illustrated in Fig. 4. This chassis has a wheel base of 14ft. 9in. to carry a lorry body 18ft. long. It is rated to carry 8 tons gross and is propelled by a four-cylinder engine developing over 80 B.H.P., on an R.A.C. rating of 34·2 H.P. Instead of the petrol engine, Gardner or Beardmore heavy oil engines may be fitted. Seeing that the chassis weighs only about 67 cwt., the unladen weight of the lorry, even with a large body, is less than 5 tons.

Among the passenger vehicles the "Venturer" double-decker made its first appearance at the Scottish Show last year. A notable feature of the chassis is the method of reinforcing the frame at the point where it sweeps up over the front axle. There are inserts which double the section of the frame, a pressed cross member, the ends of which turn back inside the side members, and a channel section cross member attached by strong angle brackets forming a front body support and carrying a complete front bulkhead for the body. The frame extensions for the rear platform are forked at their front ends and attached to the frame by well-spaced bolts, giving a more than usually rigid support. Both these features should help to reduce the body maintenance costs.

Besides the vehicles shown on this stand there are several Albion vehicles elsewhere in the Exhibition. On the stand of Northern Counties Motor and Engineering Company, Ltd., there is the new "Victor" 24/26-seater. A new type of engine developing 60 B.H.P. is fitted to the chassis and, besides the engine, the clutch and gear-box are also beneath the bonnet. The arrangement has the advantage that the floor of the coach need not be lifted when gear-box lubrication becomes necessary.

DENNIS BROTHERS, LTD.

Among the firms exhibiting completely new chassis is Dennis Brothers, Ltd., of Guildford. There are three new types altogether, but the features of all closely correspond. They are suitable for a 40–45-cwt. goods carrying vehicle, a 3½-ton six-wheel lorry, and a 20-seater coach respectively, the first-mentioned of which is illustrated in the engraving, Fig. 5. It will at once be observed that the front axle is set well back, and that forward control has been adopted. In consequence, the load is distributed evenly over all six tires, the rear axle with its double wheels taking approximately twice as much load as the front axle. Since the engine is set well forward, it is rendered remarkably accessible. Bodies up to 13ft. in length can be fitted, while a turning circle of only 35ft. 6in. is made possible by the front axle design. The pivot pins are arranged inside the front hubs, as may be seen from Fig. 6. The engine has four cylinders and develops 60 B.H.P. at 2250 r.p.m. An interesting feature of the radiator design is that it is made in four sections individually detachable by the removal of two bolts—see Fig. 7. This arrangement is distinctly valuable, for if the radiator is damaged, or develops a leak from any cause, only the section concerned need be replaced, and the operation may be quickly performed. The safety of the vehicle when travelling fast or in congested neighbourhoods is catered for by the fitting of hydraulic brakes. Shoes, 4½in. wide, are fitted at the back and 3½in. wide at the front.

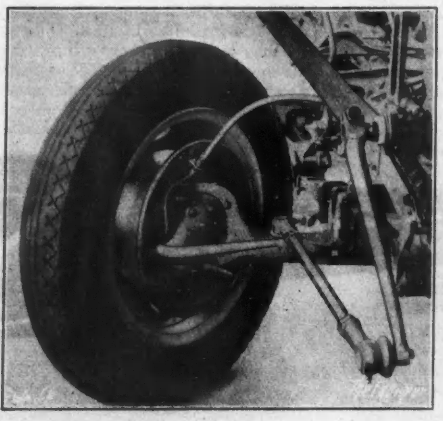

FIG. 6—FRONT WHEEL OF 40/45 CWT. CHASSIS—DENNIS

The design of the 3½-ton six-wheeler follows closely that of the smaller chassis. Its wheel base is, of course, larger, being 11ft. 8in., and the frame is deeper and wider. The trailing wheels are mounted on stub axles secured to the rear ends of rocking beams, to the front ends of which are shackled the rear ends of the rear springs. Bodies up to 15ft. 3in. in length can be fitted and, in accordance with the greater load, the hydraulic footbrake is servo assisted. It operates on all six wheels.

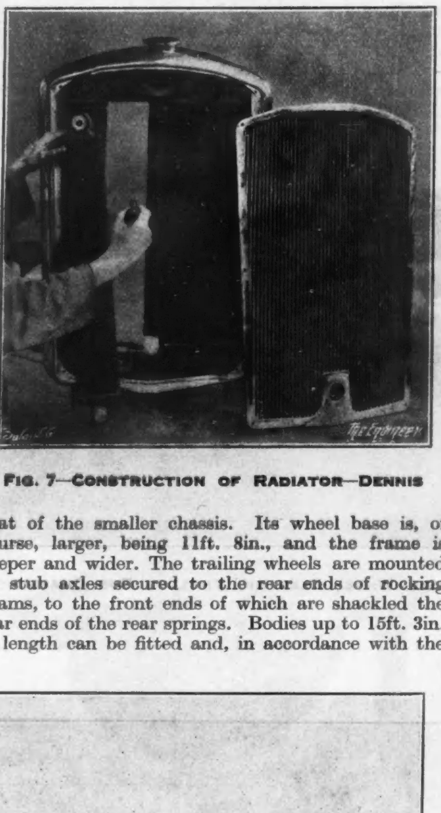

FIG. 7—CONSTRUCTION OF RADIATOR—DENNIS

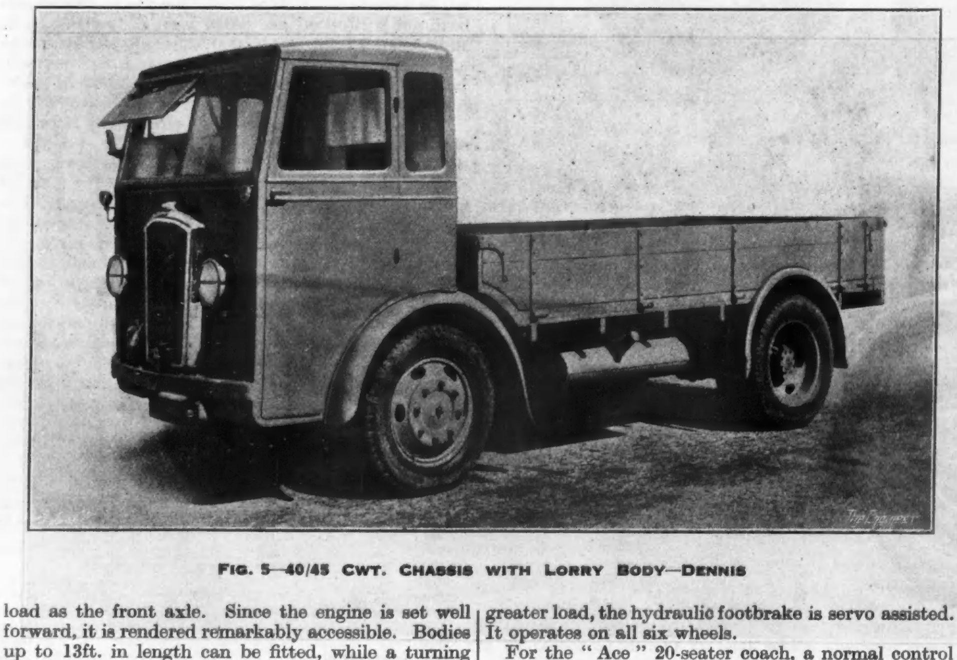

FIG. 5—40/45 CWT. CHASSIS WITH LORRY BODY—DENNIS

For the "Ace" 20-seater coach, a normal control arrangement has been adopted. The chassis is similar to that of the 40–45-cwt. vehicle, but larger, to provide space for a body 18ft. long on a wheel base of 11ft. 6in. The turning circle becomes 40ft. 6in. diameter. In accordance with modern ideas, the interior of the coach is richly furnished and has luggage racks, rug rails, ash trays, &c.

On the "Lancet 6" chassis a coach body providing seating space for thirty-one persons has been fitted. It is of the modern stream-line form, and is a new design having a sliding door for the front entrance and an emergency exit at the rear. As the cab is made the full width of the coach, there is space for the carriage of luggage beside the driver. Other models on the stand are a Lancet chassis for a 32–36-seater body driven by a four-cylinder engine; another fitted with a double-deck body built by Metropolitan-Cammell-Weymann Bodies, Ltd., to seat fifty persons, is fitted with a six-cylinder Armstrong-Saurer oil engine, developing 97 B.H.P. at 1800 r.p.m.; and lastly an 80 H.P. rescue tender and canteen van for the West Ham Fire Brigade.

THE SUNBEAM MOTOR CAR COMPANY, LTD.

Among the exhibits of the Sunbeam Motor Car Company, Ltd., of Moorfield Works, Wolverhampton, is the Sunbeam "M S 3" six-wheel low-loading trolley omnibus chassis, shown in Fig. 3. It is designed for a double-deck body with accommodation for fifty–sixty passengers, and by offsetting the motor and transmission an exceptionally low-loading platform and lower saloon floor are obtained. The motor is placed amidships under the seats, thus permitting a clear floor free from obstructions. A short propeller shaft fitted with a universal joint at each end connects the motor with the foremost rear axle. The resistances are placed amidships on either side of the nearest frame member in an accessible position. Main and shunt contactor panels, claimed to be silent in operation, are mounted in the driver's cab. The master controller, secured to the front dash, is operated by a pedal designed to give easy control. A special sub-frame, mounted on four silent bloc bushes, carries the motor and provides a floating housing which permits rapid and easy removal when necessary. It is completely insulated from the main frame, and from the transmission by a rubber and steel coupling, an arrangement that is of considerable importance when an all-metal body is mounted on the chassis.

A third differential mounted on the middle axle ensures even distribution of the driving torque between the two road axles. The brakes are of the Lockheed hydraulic type, with provision for cooling the cylinders, and they operate directly on all the wheels with a minimum loss of power. The system is controlled by a patented master cylinder, which is claimed to give perfect compensation and to ensure protection from complete failure of braking in the event of fracture of any of the pipe lines. Low maintenance costs, infrequent adjustments, and long life are the advantages claimed for the system, a full-scale model of which is shown. Between the foot pedal and master cylinder there is a Dewandre vacuum servo, which serves to reduce the foot pressure required for operation. The vacuum tank is exhausted by a Reavell rotary exhauster driven directly from the forward end of the B.T.H. regenerative motor, which is designed for heavy overloads and for generating at speeds down to 10 miles per hour.

The Sunbeam patented low-voltage lighting system is arranged so that the 40-ampère-hour battery is only used to supply the small amount of current required for the legal lights and accessories regularly in service, such as the screen wiper, horn, bells, &c., the main current load being supplied directly from a motor generator unit. This set consists of two distinctly insulated machines with a continuous rated capacity of 1000 watts, the dynamo delivering current at 24 volts. The high-voltage portion of the unit is entirely insulated from the main frame or body, and provision has also been made for reducing noise and vibration. A switch is arranged so that when the main interior lights are switched on the motor generator is started, and during the period the main lights are in service and the motor generator set is running, the legal lights and accessories are supplied directly from the dynamos and the battery receives a regulated charge.

The chassis is of robust construction, and all the units are accessible. The following is a brief specification:—

Wheel base..	16ft. 8in. from front axle to centre bogie
Wheel base of bogie	3ft. 11½in.
Frame height, laden	2ft.
Frame height of platform, laden	11in.
Overall length of chassis	27ft. 0¾in.
Overall width	7ft. 5½in.
Turning circle (10·5—20 tyres)	Under 60ft.
Front and rear axle track ..	6ft. 4¾in.
Speed	30 m.p.h.
Tyres	10·5—20in. Dunlop low pressure
Motors	B.T.H. 201 compound wound
Resistances	B.T.H. jointless unbreakable
Circuit breakers..	B.T.H. type M.R. 504
Three differentials	
Ratio	10·33 to 1

(To be continued.)

WORK is being started on the construction of a large grain elevator at Fort Erie, Ontario, at a cost of 1,750,000 dollars.

Railway and Road Matters.

The Board of the Institute of Physics has elected Mr. A. E. Tattersall, the signal and telegraph engineer, North-Eastern area, London and North-Eastern Railway, to be a Fellow. We understand that Mr. Tattersall is the first railwayman to receive this honour.

Speaking at the Boatmen's Institute the other evening, Mr. G. Thatcher, assistant manager of the Grand Union Canal Company, said that anything up to a million tons of goods passed annually through the heart of London in the canals without the slightest noise or inconvenience to anyone.

The oldest railway "servant" in Great Britain is believed to be the signal-box bell at Hebden Bridge, Yorkshire, L.M.S. Station, which for ninety-four years has been sounded to herald the stopping of each passenger train. This railway veteran, which bears the inscription "Manchester and Leeds Railway Company, 1839," is still going strong, and it is estimated that it has been rung over 3,000,000 times.

The Board of Trade export table for September shows that during the first nine months of the present year railway material of the following value was sent overseas, the figures for the corresponding nine months of 1932 are added in brackets:—Locomotives, £708,500 (£262,286); carriages and wagons, £358,364 (£538,284); rails, £414,274 (£267,059); wheels, metal sleepers, fish-plates, and miscellaneous material, £558,645 (£592,338).

The Railway Returns for 1932 show that on December 31st last there was a total of 21,555 steam, electric and petrol locomotives, a decrease of 818 during the year. The average empty weight per steam locomotive increased from 47·06 tons to 47·58 tons. The total number of passenger-carrying vehicles was 49,077, a decrease of 707. These had seating accommodation for 2,757,303, a decrease of 15,409 seats. The stock of Pullman cars rose from 229 at the end of 1931 to 261.

On account of the bad water supplies common in North Africa, the Algiers–Oran Railway is contemplating the adoption of oil locomotives, and has recently acquired one of French make. It has an eight-cylinder engine of 920 horse-power, when running at 700 revolutions per minute. Transmission is effected electrically to three motors on the three driving axles. The engine has been proved to be capable of a speed of 75 miles per hour, and will have to work under an atmospheric temperature of 122 deg. Fah.

Experiments which are being made by the L.M.S. Railway at Burnley and Huddersfield, represent, it is believed, the first instances in this country of the employment of slat conveyors for handling miscellaneous general goods traffic direct from rail wagons to road vehicles. The installation at Burnley (Bank Top) goods depôt consists of a slat conveyor, 365ft. long, electrically operated by a 40 H.P. motor working off 400 volts. The conveyor works in a continuous line between the wagon berths and the cart-loading deck. Goods are conveyed from rail wagon direct to the lorry or rail tranship wagon without intermediate trucking, the resultant benefits including increased speed of handling, earlier delivery of traffic to traders, and the avoidance of damage.

It was forty-five years ago on November 1st since the Midland Company's branch from Staveley to Elmton and Cresswell was brought into use. The line was only 7 miles long, and its opening was a minor event. It had, however, the distinction of being the first section of the Midland Railway to be worked by Tyer's tablet system for controlling single lines. A more important railway was opened forty years ago on November 6th. That was the Dore and Chinley, also of the Midland Company. A private company obtained, in 1884, the initial powers to build the line, but was unable to raise the necessary capital. The Midland thereupon acquired the undertaking in 1888. The line runs from Dore, on the main line to the North, to Chinley on the Manchester line, and gave the company through communication between Sheffield and Manchester. It is 20 miles long with a north and south curve at each end; Totley tunnel is 6226 yards long, and Cowburn is 3727, and the gradients, particularly on the approaches to those tunnels, are severe, with long stretches of 1 in 100. Mr. E. C. F. Trench, who, until four years ago was engineer-in-chief to the London, Midland and Scottish Railway, was one of the resident engineers on the Dore and Chinley.

It is officially announced that the branch line of the London and North-Eastern Railway from Spean Bridge on the West Highland to Fort Augustus at the southern end of Loch Ness, is to be closed to all traffic on December 1st. The history of that romantic and exceedingly picturesque railway has been told by Mr. A. Newlands, then the chief engineer of the Highland Railway, and subsequently and until June 30th last, the chief civil engineer of the London, Midland, and Scottish. The story first appeared in article form, and in 1921 was published as "The Scottish Railways: A Sketch of their Growth and Recent Developments," by the *Railway Gazette*. It began by saying that no review would be complete without a reference to the persistent and determined attempts on the part of all the railway companies to obtain possession of the Highlands. "The cunning and daring of the worst of the old Highland 'Caterans' in their southern raids of long ago did not excel the wiles and persistency of the Scottish companies in trying to wrest from the Highland Company a portion of its territory." In 1893 both the Highland and the North British deposited rival Bills for the construction of a railway through the Great Caledonian Valley, but by agreement between them the Bills were withdrawn. The line between Spean Bridge and Fort Augustus was subsequently built by a private company and opened on July 22nd, 1903. The Highland was empowered to work it, but, on April 30th, 1907, that ceased, owing to the loss to the working company. The North British took it over and operated the line until October 31st, 1911, when the railway was shut down by the owning company. On August 1st, 1913, the operation and maintenance were again taken over by the North British, in which company the line was vested in consideration of the sum of £29,500, of which £5000 was contributed by the Inverness-shire County Council.

Notes and Memoranda.

The improvement in the position of the British steel industry this year is indicated by the fact that the average production of steel for the first eight months was 537,700 tons, compared with monthly averages of 438,100 tons in 1932, 433,500 tons in 1931, 610,500 tons in 1930, and 638,600 tons in 1913.

A Norwegian engineer named Skogen has, according to the *Marine Engineer*, invented a type of propeller in which the blades are divided into two or three parts with long intervening spaces. Trials of the radially slotted propeller on a motor boat are said to have proved that the same vessel's speed can be maintained with a propeller speed one-third lower than that of an ordinary screw.

An official return indicates that the general industrial depression is continuing seriously to affect the overseas demand for American electrical machinery and apparatus. The exports of such material from the United States during the six months ended June last attained a value of £3,472,930, as compared with £4,819,380 in the corresponding half of 1932, and £9,053,120 in the similar period of 1931.

A Fuel Research Technical Paper just issued by the Department of Scientific and Industrial Research deals with the determination of the viscosity of pitch. An important technical application of pitch is as a binder in the manufacture of briquettes from powdered coal. The investigation described formed part of a programme of work designed to correlate the laboratory tests of pitch with its suitability for briquette making, but it is probable that the results will also be applicable to other branches of industry. The report can be obtained from H.M. Stationery Office, price 6d.

According to the *Daily Telegraph*, Monsieur Nicholas Florine, an engineer of Russian birth, but a naturalised Belgian, announced at a meeting of members of the Government and scientists that he had devised a means of enabling an aeroplane to hover for several minutes. He has been conducting experiments for two years. The machine he employed is a helicopter weighing nearly a ton, with a motor of 200 horse-power. It has two propellers turning in the same direction, but with the axes inclined in relation to one another. In experimental flights the machine hovered for 6½ minutes at the first attempt and for 9 minutes 58 seconds at the second. This is claimed to be a world record.

Among the results recently found in weathering tests of paints by the German railways is the fact that a natural coating of oxide on steel forms such good protection against rust that its removal prior to painting is not desirable, even to secure better adhesion of the paint film. Surfaces freed from rust by sand-spraying are frequently more sensitive to wear than those which have been freed from rust by hand. Preliminary surface treatment by phosphatising by the Parker or Atrament processes has so far given no definite results. Steel containing a small percentage of copper (0·2–0·25 per cent.) is more anti-corrosive, and has the additional advantage that not only does the paint adhere better, but the further progress of rusting is inhibited by formation of copper oxide.

A committee on bituminous waterproofing and roofing materials of the American Society for Testing Materials has presented a valuable report on accelerated weathering tests of bituminous roofing materials, and also a critical review of the results obtained in the refined ductility tests for bituminous roofing materials reported last year. Important studies undertaken by the Committee include analytical methods for membrane roofing materials, test methods for bituminous emulsions used for waterproofing, test methods for bituminous joint compound for sewer pipe, and studies of expansion coefficients of bituminous products. Papers of interest in connection with the work of this Committee were presented by J. M. Weiss on "The Volatile Combustible Matter of Coal Tar Pitch," and by G. W. Clarvoe on "An Apparatus and Method for Measuring the Consistency of Roofing Putties and Fibrous Roof Coatings."

In the course of some remarks made at the annual meeting of the Cast Concrete Products Association, Dr. Stradling said that the cause of crazing had definitely been discovered and the next step towards its prevention or cure came from the manufacturers' own practical experience. As the result of their pooling of knowledge, together with the technique in which his staff had been trained, Dr. Stradling said that, in his opinion, the problem of crazing had practically been solved from the scientific point of view—solved not by the laboratory alone or the manufacturers alone, but by a combination of the two working in conjunction. Dr. Stradling proceeded to say that he did not mean to imply that the practical problems were over, as it was not known whether the process which was being tried out in the laboratory would be successful. The theory was right and they were working to devise some means which could be installed in works in order that it might be possible to give a commercial guarantee against crazing.

The effect of mill-scale on the good behaviour of paint varies enormously with the type of scale, according to a paper read before the Electro-Chemical Society, of America, by Messrs. U. R. Evans and S. C. Britton. The lower scale on wrought iron can often be left in position without serious effects. The mill-scale on steel varies very much according to rolling conditions. In general, in the authors' tests, descaled steel covered with a good paint has begun to show rust stains sooner than corresponding specimens painted over the scale, but the paint, although rust-stained, has usually remained firmly attached, so that fresh coats can be applied without ill effects. On the scale-bearing specimens, however, attack has sooner or later commenced at cut edges or at breaks in the scale, and this attack has then proceeded sideways just below the scale, undermining it and causing scale and paint to flake off together; in such a state, repainting without thorough scraping is quite useless. For the present it seems that descaling previous to painting is for certain purposes a desirable practice, but it cannot be said that the matter is fully cleared up.

Miscellanea.

The output of the Ketton Portland cement works has just been increased from 75,000 tons to 150,000 tons a year.

It has been decided to construct a new rain water tank of two million gallons capacity within the Rock of Gibraltar.

It has been decided to continue the Plastics Industrial Exhibition at the Science Museum, South Kensington, until January 15th, 1934.

It is estimated that the cost of rebuilding the No. 2 pier at Halifax, Nova Scotia, which was damaged by fire in September, will be 360,000 dollars.

Another train ferry has been ordered in England, by the Nanking Government, for the service across the Yangtze River between Nanking and Pukow.

A large factory which, it is expected, will supply the whole of the home demands for heavy chemicals is to be put up in Bulgaria at a cost of 20 million leva.

The Lady Gwendoline Tin Mine, Cornwall, has been de-watered and got ready for working again. Already 12 tons of concentrates have been sent to the smelters.

The tunnel, 3½ miles long, which is to convey water from the new reservoir of the Galloway Water Power Company to the power station at Glenlee, has been holed through.

South Wales has received its first cargo of Newfoundland iron ore in connection with the recent barter transaction, under which Welsh coal will be exchanged for Newfoundland ore.

The official returns to the Electricity Commissioners for September show that 1,023,000,000 units of electricity were generated by authorised undertakers in Great Britain during the month, representing an increase of 10·8 per cent. as compared with September, 1932.

The quay on the river Thames frontage of the Wandsworth Gas Company is being extended and equipped with hydraulic cranes, so that coal may be brought right in by sea-going steamers. A new plant for recovering benzole and for screening and grading coke is also being erected.

The recently completed Nizamsagar Dam across the Manjra, a tributary of the river Godavary, in India, has a storage capacity of 29,700 million cubic feet and will provide irrigation water for over 1000 square miles of land. The dam is about two miles long and has cost £3,000,000.

A noteworthy feature of the Northern Rhodesian mineral returns for August is that for the first time cobalt was mined on a large scale. This mineral was first produced in the territory at the beginning of the present year; in August the output was 40,000 lb. odd, valued at over £16,000.

"The skyscraper has been a piquant and picturesque episode in the evolution of our American architecture, but the signs are unmistakable that its irresponsible vogue is near an end," is the claim of Charles D. Maginnis, Vice-President of the American Institute of Architects, in a recent article on modern trends in architecture.

J. Waldo Smith, chief engineer of the Board of Water Supply of New York City, during the construction of the Catskill water supply system, and consulting engineer to the Board since his retirement in 1922, died suddenly of heart failure on October 14th, at his residence in New York City. He was seventy-two years of age.

Field investigations by the Canadian Department of Mines appear to indicate that at least 750 million tons of bituminous sand can be mined by open cut methods in the northern portion of the Province of Alberta. On a basis of 12 per cent. bitumen content this is equivalent to 80 million tons of bitumen or 450 million barrels.

According to the *Chemical Trade Journal*, the Nostell Colliery, Ltd., Nostell, near Wakefield, is installing the system of low-temperature carbonisation invented by Mr. H. P. Hird, a director of British Carbonised Fuels, Ltd., Bradford. It is intended that the ultimate capacity of the plant shall be 200 to 250 tons per day. The first unit will be in operation in January, 1934.

During six months, from April to September this year, the passengers, mails, and freight carried on the Imperial Airways routes to Egypt, India, Burmah, and Africa showed an all-round increase of 45·54 per cent., as compared with a similar period in 1932. The percentage increase in passengers was 43·92 per cent. In mails it was 46·18 per cent., and in freight 40·59 per cent.

We are informed that the Federation of British Industries has undertaken to organise British participation in the Levant Fair and will act as official representatives of the Fair in Great Britain. A permanent British Pavilion is to be erected and a large area reserved for future expansion as well as for the private pavilions of British firms. The Department of Overseas Trade is supporting the F.B.I. in the work.

The date for the opening of the next annual meeting of the Institution of Naval Architects will fall on Wednesday, March 21st, 1934. A summer meeting will be held in London next July, at which a special feature will be the reading and discussion of papers on ship resistance problems as investigated by research in experimental tanks. Delegates from abroad representing the principal tanks of the world will be invited to attend.

A large consignment of rubber hose for use in connection with railway braking systems was recently despatched from Silvertown to China, and, at the request of the Chinese authorities, was covered with metal. The reason for this precaution is intriguing, for it was not connected with the climatic conditions, as might be imagined. It appears that, in the past, the rubber has often been torn away and at first train wrecking motives were suspected, but when the truth came to light there were found to be no sinister intentions. The Chinese had found that the rubber made excellent shoes and, regardless of any disastrous consequences to the trains, were in the habit of taking slices from the hose when their stock of footwear was running low. The metal covering will, it is hoped, put a stop to this practice.

ADMIRALTY CONTRACTS.

Shipbuilders and engineers who specialise in naval construction are looking forward with some confidence to a revival of business in the near future. For months past persistent reports have been current to the effect that a new and long-term shipbuilding programme is to be introduced next year with the object of making good the most obvious deficiencies in our naval defence. So far, it is true, these reports lack official confirmation. On the other hand, there are unmistakable signs that the country is waking up to the vital necessity of maintaining the Navy at adequate strength, and is no longer disposed to accept with equanimity the palpable weakness of our first line of defence. When introducing the 1933 Navy Estimates last March, the First Lord of the Admiralty made it clear that they had been dictated more by the requirements of economy than the actual needs of the service. Since then we have been warned by Earl Beatty and the First Sea Lord, in language the more impressive because of its restraint, that our present rate of expenditure on the Navy is not sufficient to achieve that measure of security which is essential to a country that literally draws its sustenance from the sea. Admiral Sir Ernle Chatfield was debarred by his position from stating the case quite as bluntly as we have put it, but no other interpretation can be placed upon what he did say. It is, in our opinion, all to the good that the Naval administration should speak out at the appropriate time. A Board of Admiralty that remained silent while the foundations of national sea power were crumbling away would be unworthy to hold office. We say this in full recognition of the fact, which Admiral Chatfield was careful to emphasise, that the function of the Admiralty is not to determine policy, but to implement the policy decreed by the Government.

The truth of the matter is that the policy of one-sided disarmament which this country has pursued for ten years has failed. We are not going to pretend that it was adopted purely from motives of altruism. Financial solvency is as much a safety factor as strong armaments, and radical measures had to be taken to restore the nation's Budget to a condition of health. Rightly or wrongly, successive Governments chose to retrench the fighting services more drastically than the social departments, the result being that for many years our expenditure on the former has borne no true relation to their requirements. Neither at sea nor on land, nor in the air, have our armaments been maintained at any fixed standard. Taking the Navy alone, it has already yielded first place in more than one important element, such as size of *personnel*, and every year has witnessed a further decline in its relative strength in man-power and material. Other symptoms of deterioration, less apparent to the public, have been noticed by close observers. To-day, for the first time in modern history, ships are being built for the British Navy which are inferior in many respects to contemporary foreign types. This seems to us a very serious departure from traditional practice, and a form of economy which is most difficult to justify. Another and less obvious consequence of persistent retrenchment at the expense of the Navy has been the steady shrinkage in our mechanical resources for meeting a sudden emergency. Naval armament plants in this country, the finest in the world, have remained virtually idle for more than a decade, and if the process of dismantling them has not been carried to extreme lengths that is largely because their controllers have shown a public spirit and, perhaps, a degree of prevision for which they receive small credit. Even they, however, could not prevent the partial disbandment of that army of highly trained artificers who built the ships of our present-day Fleet. We have said that economy was one of the motives which impelled Great Britain to reduce her Navy, but, side by side with this, was the hope that our example in accepting a quantum of naval strength below our visible needs would be followed abroad. That hope has proved vain. On every hand we see foreign nations busily and purposefully enlarging their war fleets. Five months ago the United States adopted a naval programme embracing forty ships, all of which are to be built within three years at a cost of about £50,000,000. Japan has framed a building scheme of much the same dimensions. France and Italy, both of whom declined to subscribe to the limitation clauses of the London Treaty, have been steadily turning out cruisers, destroyers, and, above all, submarines. Each of these four Powers has, in effect, pursued an independent naval policy determined by what are considered to be the requirements of national safety. Great Britain alone has elected to live, as it were, from hand to mouth, her naval policy—if she had one at all—the shuttlecock between economy and idealism. That game has gone on too long. It is time, as the First Sea Lord admonishes us, to take stock of the situation. Our naval defences are disintegrating, and remedial measures must be taken without further delay. That is why the forecasts of a substantial programme of new construction to extend over several years are probably well founded, and why the industries which have suffered most directly from naval retrenchment are looking to the future with renewed hope. As an example of the tardy rate of building in recent years may be mentioned the fact that work is still proceeding on one or two ships that were authorised as far back as March, 1930, viz., the cruisers "Orion" and "Neptune," at Devonport and Portsmouth respectively. The programme for 1931 has also been so delayed that none of the larger vessels will go afloat before the New Year. One cruiser, the "Amphion," was laid down as recently as last June, twenty-seven months after the date of authorisation. The only contract-built cruiser of this programme, the "Ajax," on the stocks at Barrow, is not due for completion before 1935. Belonging to the same programme, and all building in private yards, are eight destroyers, two submarines, two sloops, and a gunboat. In the 1932 Estimates provision was made for the construction by contract of two cruisers, a flotilla leader, and eight destroyers, two submarines, two sloops, a destroyer depôt ship, and a river gunboat, the orders for which were placed some months ago. The 1933 programme is practically a repetition of that for the previous year, save that the number of cruisers has been raised to four. This increase, however, is largely offset by the fact that three are to be of the small and lightly armed "Arethusa" class—5200 tons, six 6in. guns—which, although of value as fleet scouts or flotilla flagships, are not very suitable for commerce defence. As yet only one contract for a vessel of the 1933 programme has been placed, that for the convoy sloop "Bittern," with John Brown and Co., Ltd. It is understood that the remaining ships will not be ordered before next February or March. Every unofficial forecast of next year's programme includes a number of convoy sloops, a type which the Admiralty is reported to be anxious to develop in order to eke out our slender force of cruisers proper. The first vessel of this type, as already stated, has been ordered in advance. Except that she is believed to be of 1500 tons, little is known about the "Bittern." Most naval men would, we believe, prefer a larger ship for convoy work, and it is important to remember that under the London Treaty we are free to build craft of this type without limit so long as they do not exceed 2000 tons, though restrictions are placed upon speed and armament.

Whether or no the promised long-term programme materialises, there is sound reason to anticipate a larger percentage of new construction in the Estimates for next year. In well-informed quarters a substantial increase in cruiser and destroyer tonnage is expected, to make good in part the alarming wastage in these categories owing to age. More than one-third of our present cruiser tonnage is over the age limit of sixteen years, and, therefore, obsolete, while not less than two-thirds of the destroyer flotilla has passed the official span of life. By the end of 1936, when the London Treaty expires, a very large proportion of our naval material will be out of date, and, consequently, not dependable for active service. This is a serious position, the more so in that every other first-class navy will, by the date in question, consist mainly of new tonnage. In his speech at Sheffield recently, the First Sea Lord observed that the Admiralty looked to the skill of shipbuilders and engineers to ensure that whatever new ships the Navy may need will be of superlative quality. They will not look in vain. Once the Government makes up its mind to restore the Navy to that standard of strength which the national safety dictates, the great industries concerned will perform their part faithfully and well. When the great Naval Defence Act of 1889 was passed, doubts were openly expressed as to whether the shipyards and arsenals of the country could cope with the immense flood of new work. As is well known, the great programme was carried through without serious hitch, and this demonstration of our power to create new fleets at short notice had a most salutary effect on foreign opinion. If it is in the last degree improbable that any new building scheme on the scale of 1889 will be forthcoming, there are, nevertheless, good grounds for hoping that the future holds a brighter prospect for all the industries which cater for the needs of the Navy.

Renaissance.

In the printed form of Mr. Alan Chorlton's address, more than in the extempore address which he actually delivered, he reveals himself as a convinced believer that it is by taking thought, and only by taking thought, that this nation can increase its industrial stature. His panacea for the complaints from which he tells this country that it is suffering, is more and more organisation, more and more collaboration, with less and less *laissez faire*, and less and less individual action. He would even set up a Council to prosecute "Research for New Industries," to replace those "which are either leaving us altogether through the competition of other countries, or which will in future considerably reduce their output and the number of hands they employ." He scatters the pages of history with indifferent hands. It is nothing to him that the industry and profession which he adorns owe everything to individual endeavour, to rivalry, and to competition. The world has not been brought to its present position of material comfort by committees and councils, but by the struggles of pioneers, by the efforts to beat a competitor in price or outdo a rival in excellence. All this Mr. Chorlton acknowledges, but he holds that times have changed and that the old plans are no longer as valuable as they were—"what sufficed in the earlier times is now quite inadequate to meet the difficulties of to-day." He seems to demand that a superior intelligence in the form of a Committee should direct the affairs of the nation, and that the individual, save perhaps as a personality directing mass intelligence, should no longer be encouraged.

Mr. Chorlton, we need not say, is by no means alone in these views. Indeed, they might almost be regarded as the current convictions of the day, which sees—or did see till recently—salvation in "rationalisation," and still believes that the best way to make industrial progress is to absorb or be absorbed by your competitors. Is it not possible that this is a phase of modern thought induced by the peculiar conditions which have prevailed since the war, and particularly by the world depression? Some years hence, it may be interesting to turn back to the flood of literature which has swept over the world in the last few years, and has culminated in the Blue Eagle scheme in the United States. With few exceptions, the authors regard the conditions of the day as permanent. They do not visualise a natural return to those which prevailed but a few years ago. Because the world has seemed different for a decade they think it has changed in perpetuity. They forget that this is not the only slump that we have passed through. They forget that the world rose from other depressions and resumed its old courses in contentment and prosperity. Many of them write as if winter had settled down permanently upon industry, a new ice age, and that there was nothing to do but put down national central heating at once. It may be—who shall say?—that these Cassandras are in the right, and that nothing less than unremitting efforts by committees and the State can save industry from decease; but, equally, it may happen that the revival, which seems indeed to have begun, will render nugatory or unnecessary the machinery which inventors are devising for lifting industries out of the slough. If we are taking thought now, we are taking it too late. The schemes which are now being advanced for this thing and that should have been put into operation at the beginning, not at the end of the slump. The doctors will suffer the chagrin of seeing the patient get well without their drugs. And when he is well, it is ten to one that he will return to old methods which served him so well in the past rather than to new which, no one can deny, are lacking in the human appeal associated with individualism. It is not as if the world stood still under the old system. The trouble is not that it failed to advance, but that it advanced too fast. People are not yet able to accommodate themselves to all that the engineer and the scientist have given them. In Sir Josiah Stamp's telling phrase: "The orderly assimilation of innovation into the general standard of life" is at the moment not taking place. The engineer has given mankind a plethora of commodities, and its metabolism—its power of usefully assimilating them—has gone astray.

Mr. Chorlton, as everyone knows, has identified himself with two great schemes of national importance—the "gas grid" and the "water grid"—but it is less well known that he desires to see engineers taking a larger direct part in ordering the affairs of the nation. "If the engineer," he writes, "is so efficient as to have forged ahead by his works, there seems every good reason why he should now take charge of the part of human activity which has fallen so far behind. . . . More definite co-ordinated direction and control for development and extension is necessary, and in this work of national importance, engineers can render good service and should have their full say." Our profound respect for the men of our profession and vocation cannot blind us to the weakness of this argument. The fact that engineers have been so successful in their own specialised work no more implies that they would make good legislators and national administrators than that the success achieved by doctors or shopkeepers especially equips them for taking "charge of the part of human activity which has fallen so far behind." The only special quality which engineers might be expected to bring to their work would be that of logical reasoning. But the logical reasoning of the scientist is very different from that of the national economist. The scientist deals with closely formulated natural laws; his working material is non-human arguments. Not so the national economist who has to handle mass psychology and must—at present—depend rather upon intuition than reason for the direction of his actions. That engineers "should have their full say," we heartily agree; but it is not yet proved that, in matters outside their own ken, they will reveal a more useful type of intelligence than is found in other men and other professions.

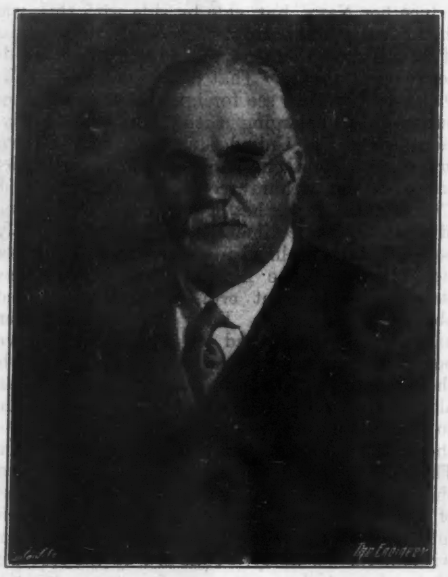
Obituary.

SIR JOHN HARVARD BILES.

Naval architects and marine engineers, both in our own country and in many lands overseas, will learn with regret of the death of Sir John Biles, which took place at his Surrey home, Highfield, Virginia Water, on Friday, October 27th. Sir John was in his eightieth year, and although during the past few months or so his health had suffered, he came up to his office quite regularly until a few weeks ago. His death thus came as a surprise to his many friends.

Few naval architects have lived a fuller and more successful and more varied life. During the sixty years in which Sir John was in practice, he always followed the latest developments of shipbuilding and marine engineering with the greatest of zest, and he himself had the satisfaction of contributing not a little to them. His own work embraced both the design and construction of naval vessels and merchant ships; he spent no less than thirty years at the University of Glasgow as the John Elder Professor of Naval Architecture, and during and since that time he built up a large practice as a consultant. He was senior Honorary Vice-president of the Institution of Naval Architects, and took an important part in the administrative affairs of the Institution and the work of the Council, on which his loss will be most keenly felt.

John Harvard Biles was born at Portsmouth in 1854, and as a boy saw the splendid wooden sailing ships of that port. He served his apprenticeship in Portsmouth Dockyard, and afterwards entered the Royal School of Naval Architecture and Marine Engineering at Kensington, which, during his training, was transferred to the Royal Naval College at Greenwich. He was the first student of his year, and after his training was finished, joined the Naval Construction Department at the Admiralty, which, later, in 1883, was formed into the Royal Corps of Naval Constructors, of his membership of which Sir John was always justly proud. In 1880, at the age of twenty-seven, he was appointed naval architect to J. and G. Thomson, of Clydebank—now John Brown and Co., Ltd.—and subsequently became shipyard manager to the firm, thereby establishing a connection with Clydebank which, through Sir John and Sir J. H. Biles and Co., has remained unbroken. His work at the Admiralty, particularly on the underwater parts of H.M.S. "Thunderer" and other naval vessels, convinced him of the necessity for shorter and broader cargo and passenger liners, and from 1883 onwards he was responsible for the design of many noteworthy ships. The "America" of 1883 made the Atlantic crossing on a record fuel consumption, while two years later the destroyer "Destructor" was built at Clydebank. In 1887 the two Inman liners, the "City of Paris" and "City of New York," were launched, which, with their shorter and broader hulls and well-planned system of hull subdivision, marked a great step forward in liner design. About this time Sir John took a leading part in the progressive change from iron to steel for shipbuilding and marine engineering, and he was attracted to the designing of fast cross-Channel steamers. His name is associated with several Channel boats, and particularly with the Fairfield-built Southern Railway Southampton-Havre turbine steamers, the "Normannia" and "Hantonia."



Sir John Biles

Even in recent years Sir John often spoke of better ships for cross-Channel work, and he was an ardent advocate of larger and longer and deeper ships, with appropriate docking facilities in this country and in France. It is of interest to record that one of his latest patents was for a new system for dry-docking train ferries in which, by the employment of a dock closely fitting the hull of the ship, it is made possible to vary appreciably the train weights without affecting greatly the displacement of the ship, thereby doing away with the long steel aprons generally associated with train ferry landing operations.

In 1891, Sir John was appointed the John Elder Professor of Naval Architecture at Glasgow University, an appointment which he held with honour for thirty years, resigning in 1921, when he received the honorary degree of LL.D. He was also an LL.D. of Yale University. Although, perhaps, not one of the greatest teachers of that great University, he did, with his strong personality, endear himself to his students and private pupils, and in later life he had the great satisfaction of seeing many of them, alike in this country, in America, and in Japan, rise to the highest ranks of the profession.

On relinquishing his University post, Sir John devoted his time to building up his practice as a consulting naval architect and marine engineer. For many years he had served the leading British shipping concerns. His wide knowledge was in constant request for Royal Commissions, Departmental Committees, and Board of Trade inquiries, among the many of which we may perhaps single out for mention the Dreadnought Commission of 1912, the "Titanic" inquiry, and, more recently, the "Vestris" inquiry. He wrote a special article for this paper soon after the loss of the "Titanic"—see The Engineer, April 19th, 1912. He had a singular gift of clearly stating his opinions, and this clarity of expression was greatly appreciated in the many cases in which he was called upon to give evidence. He was knighted in 1913.

Throughout his life he was a personal friend of the late Sir Charles Parsons, and in the early experiments with the steam turbine he supported Sir Charles with his knowledge and advice. Right to the end he remained a strong defender of the steamship, and took the greatest of interest in the varied means for using economically our British coal supplies, collaborating with his partner, Admiral Scott Hill and his staff, in a close investigation of the possibilities of pulverised fuel at sea. He took a real interest in the engineering side of his work and was a member of the Institution of Civil Engineers. His war services included the designing and the supervision of construction of river craft for Mesopotamia, which were recognised by the Secretary of State for India in Council, when, in 1922, he was made a Knight Commander of the Indian Empire. In 1923 to 1924 Sir John was a member of the Indian Mercantile Marine Committee, and the following year he served on the Committee for Royal Dockyards and their organisation, while from 1925 to 1926 he was chairman of the Engineering Joint Council. His published works included "The Steam Turbine as Applied to Marine Propulsion," and "The Design and Construction of Ships," which was to be followed by a third volume, which, however, he did not find time to write.

Reference may be made to his many papers and contributions to the "Transactions" of the Institution of Naval Architects, which, in themselves, are a tribute to his great knowledge and many-sided activities. Alongside his great technical and scientific knowledge, he possessed an innate capacity for business and hard work, and never spared himself. In his hours of relaxation he did, however, reveal a charming and kindly personality, and memories of after-luncheon and after-dinner conversations at the Athenæum, or at the Royal Society, will for long remain bright recollections of his own personal friends.

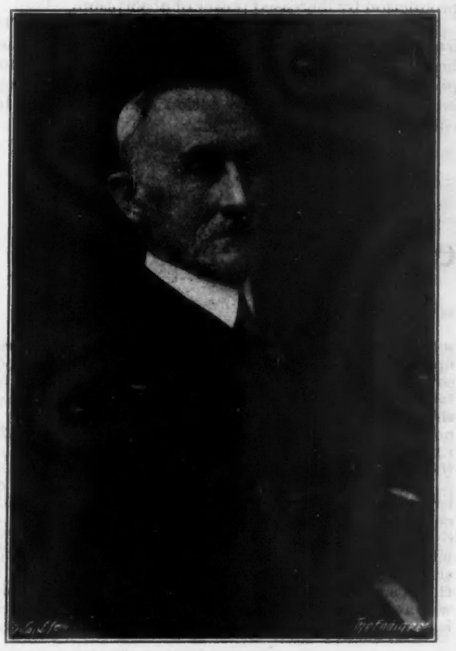
SIR ALEXANDER C. HOUSTON.

It is with very great regret that we have to record the death of Sir Alexander Houston, the Director of Water Examinations to the Metropolitan Water Board. Sir Alexander died at his home in Hampstead on October 29th, in the sixty-ninth year of his age.

Alexander Cruikshank Houston was the eldest son of Surgeon-General John Houston, of the Indian Medical Service. He was educated at Merchiston Castle School and at Edinburgh University and graduated as a Bachelor of Medicine in 1889. At a very early date in his career he exhibited an inclination to depart from the ordinary paths of a medical calling. In 1891 he graduated as a Bachelor of Science and a year later he received the degree of Doctor of Science. Questions of public health claimed his interest, and from 1893 onwards, until his appointment to the Metropolitan Water Board in 1905, he worked on various aspects of that subject for a number of different bodies. For the Local Government Board he conducted an important and prolonged investigation into lead poisoning produced by moorland water supplies. During the years 1898 to 1900 he was employed by the London County Council on sewage disposal experiments at Crossness and Barking, and subsequently studied the bacteriology of watercress beds and milk supplies. From 1899 to 1905 he served as bacteriologist to the Royal Commission on Sewage Disposal, and in the last-named year was bacteriologist to the Lincoln Corporation during the typhoid epidemic which broke out in the city. His connection with the Metropolitan Water Board may be said to date from 1903, when he was engaged in an expert capacity in the arbitration proceedings which led to the establishment of the Board as an authority superseding the old water companies. Following his appointment as the Board's Director of Water Examinations, he still found opportunity to place his knowledge and experience at the disposal of other bodies. In 1907 he acted as British representative on an International Commission appointe to inquire into the water supply of Cairo. In the sam year he took part in the Belfast Health Inquiry.

With Sir Alexander Binnie he visited Ottawa in 1913 to report on that city's water supply.

It is by his work for the Metropolitan Water Board that Sir Alexander will undoubtedly best be remembered. His annual reports on the purity of London's water supplies revealed him to be, not only a scientist, but an antiquarian, a poet, and a philosopher. These reports, while they might have been purely statistical, were enlivened and raised to a high level of literary and human interest by the infusion into them of the author's enthusiasm for his work and his love for everything connected with it directly or remotely. His attention was by no means confined to what he could see beneath the microscope or in the test tube, but ranged widely over the history and geography of London's water supplies. It would, however, be a mistake to suppose that he allowed these external interests to interfere in any way with the performance of his technical duties. He was charged with the task of protecting the sources of supply and with the solution of problems concerned with the purification of the water. In that work he acquired a world-wide reputation and rendered service, not only to the Board, but to all water supply authorities. Last year, although he had passed the age limit of sixty-five, the Board decided to retain him in his post. In coming to that decision it recorded its opinion that his work "lightened the grave responsibilities of the Board and tended to create a sense of security among those who watched over the health of the Metropolis."



SIR ALEXANDER HOUSTON

Three weeks ago it was announced that it had been hoped to retain his services until at least September, 1934, but that his health had compelled him to tender his resignation.

Sir Alexander was created a Knight of the British Empire in 1918 and a year later was made a Commander of the Victorian Order.

Institution of Mechanical Engineers.—The annual dinner of the Institution of Mechanical Engineers took place on Thursday evening, October 26th, at the Dorchester Hotel, Park-lane. The chair was taken by the President, Mr. Alan E. L. Chorlton, and more than 520 members and guests were present. After the loyal toasts had been given and honoured, the President called upon Sir Ernest W. Petter to propose the toast of "Our Export Trade." In the course of his remarks Sir Ernest referred to the difficulties which the exporter was called upon to face, both with regard to restrictive trade regulations and finance, and he appealed for further Government help in removing these disadvantages. In responding to the toast, Mr. Walter Runciman, President of the Board of Trade, spoke about the Government's difficulties in the matter of holding the scales evenly in trade agreements. As Sir Ernest Petter had pointed out, much had been done for the coal trade, which, he claimed, represented the easiest and most direct way to influence other trades. The Government, he continued, was not unmindful of other industries, and would welcome the help of engineers in solving difficulties still presented. One disadvantage in the past had been the over-capitalisation of industry, a problem which was now beginning to come to an end. He thought that the adaptability of the British manufacturer had not yet been fully exhausted, and suggested that what was most needed at present was a spirit of hope in business life. Half our population was directly dependent on export trade, and it was satisfactory, he recalled, that we were now shaping ourselves on a much more economic basis than we had since the war. The toast of "Our Home Production" was proposed by Mr. H. N. Gresley, Vice-president, who referred to the improved state of trade, which was shown by the railway traffic returns. More wagons were needed, and whereas a year ago wagons under repair were not missed, to-day more wagons were needed. The Minister of Transport, Major Oliver F. G. Stanley, replied to the toast, and commented on the remarkable safety of railway travel. He thought it was the task of the mechanical engineer to make car and road transport, which was on the increase, safer. The toast of "The Institution of Mechanical Engineers" was given by Mr. J. C. C. Davidson, Chancellor of the Duchy of Lancaster, and in his reply the President put forward a strong plea for the greater recognition of mechanical engineers in general affairs. They might be fairly regarded, he suggested, as the architects of industry.

The Engineer and Conditions of To-Day.*

MECHANICAL engineering in one form or another has been, from the early days of the industrial revolution, a most potent force in changing the easy-going ways of the "good old times" to the intensely active and involved life we have to live to-day. In that interval the country has changed from being almost entirely agricultural to being mainly industrial, and has enormously increased in population and wealth. This great period of expansion was one of mechanical invention as applied to almost all industrial processes, the steam engine, the locomotive, textile machinery, mining, iron and steel production, assisting the development of all, making possible many new industries, and constantly finding new paths for further progress.

Up to the time of the war we lived in what was certainly an age of expansion, and all our views, actions, and constructive work were based on that aspect. Our industries and mode of life were developed in such an atmosphere—what sufficed in the earlier times is now quite inadequate to meet the difficulties of to-day. The world now is a very different place from those expansive pre-war days, for it has not only reached, but has already passed through some of the years of an age of contraction.

The old *laissez faire* policy of the Victorian age, the individualism under which our industrial supremacy was built up (in which mechanical engineers played so great a part directly or indirectly), the manner of growth of our towns with their public utilities, all form part of an age now gone by, when the margin of profit available for all purposes was large and the general conditions favourable, all no doubt the result of the great industrial lead, so rapidly gained after the Napoleonic Wars, and then held for so long over other nations.

In this age the individual was predominant, or, if it were the question of a town, then in its development the will of that town alone must prevail without much regard to others surrounding it. In all this progress, whether for individuals or communities, the engineer laboured with a success so constant and so assured, as to be accepted so much as a matter of course, that in the end his real value was all too frequently overlooked. He was seldom entrusted with the original decisions; it was the financier, the politician, local or national, or the administrator who claimed the right to direct. These people, so often self-appointed, belonged to a class who had acquired the dangerous habit of believing they possessed an inherent ability to govern and decide without technical training.

That the engineer, with one of the widest trainings of all professions, was so rarely associated with these prime councils of decision may have been partly his own fault, due, perhaps, to the fact that he was largely self-centred. His work brought its own satisfaction, and he was content if his developments succeeded and led to others of an even more interesting character. He was seldom interested in world movements, being more concerned with specific problems which he could tackle on logical lines. Although the enthusiasm of the inventor stirred him to picture to himself the benefits which the application of his ideas might bring to his fellows, he probably derived greater satisfaction from the accomplishment itself. In this way he was led from one development to another, each a stepping-stone to a further success, urged forward by those who stood to gain financially to a pace in which the absorptive power of the world has quite failed to keep up with him.

Before the war, when progress was much slower, the balance between consumption and production could be maintained, and the engineer had not then experienced the intense urge to increase his speed and output brought upon him by war and post-war claims.

It seems rather strange that those who are now blaming him, in reality for his success—economists, financiers, politicians, and even those engaged in social services—do not see the implication arising from their charge. If the engineer is so efficient as to have forged so far ahead by his works, there seems every good reason why he should now take charge of the part of human activity which has fallen so far behind.

Much has been said of rationalisation, amalgamation, and co-ordination in industry, and of the need for general re-equipment. In fact, the plethora of advice given to industry by those not concerned in and without experience of it, has become wearisome by its constant reiteration. It seems rarely to have occurred to these people that such methods can also apply to the re-equipment of the country itself, quite apart from the actual industries, and that this aspect is now within their purview. From a consideration of this subject it will be seen that the need for more co-ordinated working and an improvement in our public services is urgent, if we are to increase the general facilities for industry and the amenities of social life and at the same time secure some real saving from the waste which at present obtains.

In this work the engineer, who has been responsible for the construction, erection, and successful functioning of the already existing equipment, is the one well qualified to direct and carry on the art, and it must be concluded that to bring this about most efficiently, some form of engineering and industrial council would have to be set up. We already have the Economic Advisory Council, and it is to be regretted that another body of the nature indicated was not created at the same time, and the responsibilities and duties of the two properly interlinked.

Such an industrial council has been advocated before, and there is no doubt a wide range of most useful work exists for it to carry out, on lines somewhat similar to those of the Economic Council, but in this address I am dealing with mechanical engineering with particular relation to practical schemes of public work comprised in the larger project of the re-equipment of the country.

I envisage the situation to-day as being one in which we must, as an act of government, improve the facilities of the country in proper relation one to the other as is now being done in industry, with the object of bringing them up to the same level of efficiency as that of the most advanced industry, for they contribute in no small degree to the general effort we are making to regain our position against the competition of other nations in export trade, upon which our existence so much depends.

The various public services of the country—light, heat, power, and water supply—have all been developed separately with but little interconnection, yet everyone will agree that if they had been properly inter-related, a much more efficient system would have resulted as a whole at a far smaller first cost, with greater satisfaction to those who must use them. Similarly, drainage, sewage, cleansing, and many other public utilities, have been developed piecemeal by separate towns and districts. Railways, roads, and canals also afford examples of "how not to do it," by their lack of proper inter-relation with each other, resulting in high costs, ruinous competition, and consequent waste.

Water Supply.—This, to-day, is a separately conducted service, either by municipality or by company. Generally, there are ample supplies of water, but in rural areas all too frequently they are very limited.

Numerous Royal Commissions and Committees have reported on this question during the last fifty years, and have pressed in the national interest the need for some improvement and control of the various sources of supply. They urge that it is necessary to set up a Central Water Authority to act as an advisory body, and to control the allocation of water and the collection of supplies.

The country, as a whole, is well provided for, but the rainfall of different parts is very varied. Naturally, the deposition is greatest in the hills, principally in the Pennines and in Wales.

In the past industrial development in the North has used up so much of the Pennine supply that there is little left, but it is doubtful whether industry will continue to increase there. An increase in industrial activity is indicated in the southern areas and around London, with a corresponding increase of population, whilst a decrease in population in the North may be expected.

This change will affect the water supply more than any other public utility. It is undoubtedly being felt even now, and already there is, in many northern towns, a considerable reduction in demand. Not only has the London area to face an increased demand as the new industries expand, together with that from more rapidly growing population, but the consumption per head rises also as baths become more numerous and sewage systems become universally water-borne. For the London area, with a population of perhaps 12 million, an increasing consumption per head, and the growing requirements of industry, a much greater supply will be required, perhaps ultimately twice the present amount.

If the foregoing factors are taken into account, together with the large demands that will arise in the countryside itself, it seems that we shall have redundancy in some parts of the country and scarcity in others. It is suggested that a scheme should be worked out whereby areas with heavy rainfall, like those of the hills, will provide, by suitable trunk mains, the supply to those parts of the country where it is or will be required. It is an imperative need that the whole of the available water supplies of the country should be investigated and a scheme, of which the foregoing is but a suggestion, developed by which they can be more evenly distributed, and the manner of control might be by an authority similar to that administering the electricity scheme.

Gas.—The case for expansion here bears a family resemblance to that of water, in that it also implies the inter-connection of existing undertakings somewhat upon the lines of the electricity grid. But it is also to some extent bound up with the question of long-distance supply and is a proposal of long standing.

---

* The Institution of Mechanical Engineers. Extracted from the address by the President, Alan E. L. Chorlton, C.B.E., M.P.

The proposal to generate gas at the pithead and transmit it under pressure by pipes relatively long distances to the areas of large consumption must have been brought forward in the very early days of the industry.

Though the gas industry began in this country and subsequently spread to others, it has lagged behind in regard to later developments in connection with long-distance supply, and in considering this question to-day we have to go abroad for most of our examples. There are doubtless very good reasons for this. In the earlier days installations were of a more primitive character and relatively isolated, coal was cheap to transport, and as time went on legal restrictions became so encircling and so preventive of outside development that all available talent was concentrated on the plant itself, resulting in this country taking the lead over others in the design and construction of gas production plant for towns. It is difficult to set out adequately to what extent gas has been handicapped by legislation in this country, but it has been a very real limitation.

This limitation has not only been restrictive in the distribution of profits with its obvious reaction, but generally, in the areas of distribution and supply; in effect, no gas company could act in a major sense, as, for instance, concluding an agreement with a neighbouring undertaking, except by special Act of Parliament.

No doubt, the earlier projects for the long-distance transmission of gas were based upon some simple comparison that it was more economical to transport gas than coal. To-day, however, the whole economic problem of the transmission of energy by coal, gas, or electricity, has been carefully investigated in detail, but it is exceedingly difficult to apply figures directly in every case. Considered as an engineering problem, the basis of any present-day scheme would be, as with the electricity grid, to inter-connect the highly efficient stations by trunk mains to the areas previously supplied by the older stations and in this the comparison is close.

The next condition is one in which the gas problem differs from the electrical. While special new power stations have been erected for the electrical scheme, the extra supply of gas at low cost actually comes, or will come, from the coke oven installations, either existing or being erected at the pitheads of various collieries, from which gas is blowing to waste.

The general development of coal mining, particularly in certain areas, points clearly to the considerable increase in the number of these installations. We have thus available, or shall have, a very large amount of gas for use, and accordingly the gas grid system has a considerable advantage over the electrical, both from a capital and an economic point of view.

Had the coke oven installation advanced at a more rapid rate, the question of a widespread gas supply, apart from legal considerations, would have been forced to the front earlier—in fact, before that of electricity. Examination of the two schemes reveals close similarities, but there is one important difference: the gas has, or will have, a large excess supply from which to draw, whilst the electrical undertaking has had to create it by heavy capital expenditure on new stations.

When we come to a more detailed consideration of the gas scheme, naturally we find many differences of the conditions of supply in various towns, also the thermal value of gas is not constant throughout the country. No differences can, however, be greater than those which existed in the case of electricity, and are probably less, and, moreover, they present no fundamental difficulty which cannot be overcome by patience and experience.

All such widespread schemes for the supply of our common needs—electricity, water, gas, &c., and their interworking—must be properly administered if the highest efficiency is to be obtained. As examples of interworking we can consider :—(*a*) Electrically driven pumps for the water grid, operating during periods of least demand to obtain the lowest possible rate for current; (*b*) gas engine driven pumps in the coke oven areas for the water grid; (*c*) electrically driven pumping for gas on a similar basis; (*d*) gas engine driven electric generating stations, using cheap gas from storage as the supply for peak electrical loads; (*e*) water storage systems to act through turbines on electricity supply systems; (*f*) the foregoing, combined with water supply systems in some cases.

The proper use of all these forms of energy (for each has supreme advantages in certain applications) is absolutely essential if an efficient national scheme for all is to be developed. It is one which would be in advance of any already existing in other countries.

There are a number of other common services, apart from those mentioned, in which improved efficiency, considered from the point of view of the general re-equipment of the country, would be obtained if they were so co-ordinated, inter-related, and extended.

For instance, the development of the sewerage and drainage systems of the country should promptly follow that of a general water supply. This is essential in villages where the risk of epidemic arises, not only directly, but also from the reaction on the water supply of an inefficient sewage disposal system. There is also the question of the drainage of large areas of the country, a matter which has been the subject of much investigation and of many recommendations, which, at any rate in modern times, have been carried out but rarely.

Continuing the examination of the subject, we might take that of transport, where there is already a considerable development of the modern trend of co-ordinated and centralised control. The rapid development of the commercial vehicle on the road has forced the adoption of a plan of inter-working between road and rail, and the extension of this principle will continue.

The development of waterways, examples of which are the Grand Union now in progress, and the Nottingham–Humber scheme practically completed, indicates that the long neglect of this important system of transport is coming to an end. The numerous canals that are out of use must be considered for other purposes, perhaps in certain cases for rural water supply.

Up to the present, road building has occupied far too prominent a place in the undertaking of public works. The old policy should not be revived, but there are undoubtedly many bottle-necks still left in the country which could advantageously be removed; some at the entrance to towns and others at cross roads almost nullify any gain afforded by the new main roads.

The question of road bridges and level crossings over railways is important, and a vast amount of work would arise if this were satisfactorily settled.

If we regard speed as one of the absolute needs of the railway, as compared with the road, it would not be unreasonable to assist the railways to ease their own bottle-necks. But a far more important question is that of the electrification of suburban railways. The industrial areas of South Lancashire and the West Riding of Yorkshire, densely populated as they are, and threaded by a close network of railways, are particularly suitable for such a development. It would result in much work for many trades, and a great improvement in travelling and transport facilities.

All that is possible should be done by the Government to assist these areas in retaining their particular industrial suitability, for the retention of their existing manufactures and in the development of new trades if the older ones fail. If trade fails, the migration of population may eventually leave the northern areas derelict.

Time will not permit of the consideration of every other scheme of national re-equipment which might with advantage be undertaken, but they are many, and all must bear their due relation one to the other and to the whole, and in each the mechanical engineer can play a great part. There is, however, one more service I might refer to, in which the suggested Council or a section of it might give great assistance, which I will call "Research for New Industries." The specific object of this would be to discover by intensive investigation new industries to replace those which are either leaving us altogether through the competition of other countries, or which will in the future considerably reduce their output and the number of hands they employ. Such new industries might either be of a nature similar to those they replace, or of an entirely new character, designed to assist in redressing the present balance of over-production by increased power of absorption.

The more generally accepted way, of course, is to leave matters like this to the initiative of individual firms. Under present conditions this way has not proved sufficient. World conditions are too strange and distorted; collective action seems again to be called for.

Mobile Generating Set.

SOME time ago we had the opportunity of inspecting one of the 67-kW mobile generating sets for battery charging, constructed by William Beardmore and Co., Ltd., at their Glasgow works, to the order of the Engineering Department of His Majesty's Post Office. By the courtesy of the Engineer-in-Chief to the Post Office, we are now able to describe and illustrate this machine.

These generating sets are designed to supply current for telephone exchanges at times if the normal electrical supply fails. Similar sets are now situated in London, Manchester, Birmingham, and Leeds.

Each unit, two of which are shown in Fig. 2, is constructed in the form of a complete electric power generating unit, together with all the necessary equipment usually associated with an electric generating set. The oil engine is of the four-cylinder airless-injection four-cycle type, of British design throughout, and is direct coupled to a shunt-wound D.C. generator, supplied by the British Thomson-Houston Company. The engine and generator is shown in Fig. 1.

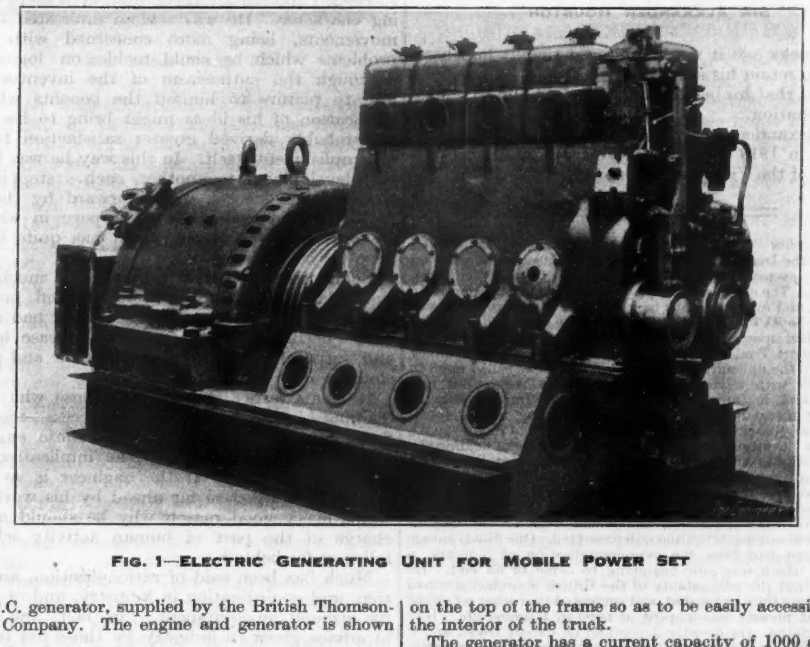


FIG. 1—ELECTRIC GENERATING UNIT FOR MOBILE POWER SET

The entire power unit is mounted on a platform built up of rolled steel channel sections, and is enclosed in a mild steel canopy. Suitable sliding doors give access to the control levers and the equipment.

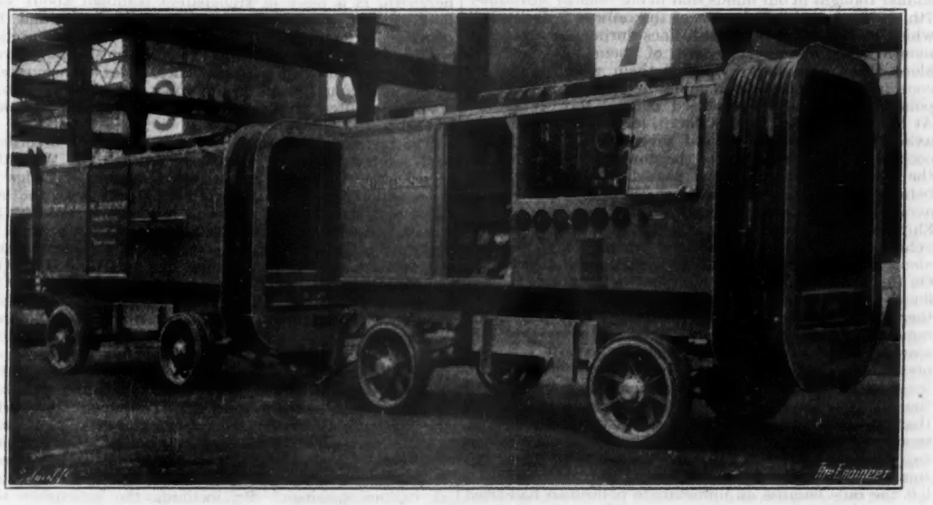
The unit is carried upon four wheels fitted with solid rubber tires, and is sprung with four semi-elliptical springs. The front axle is carried in a swivel truck with drawbar to facilitate transport. All the wheels are adequately braked, and each wheel is fitted with Timken roller bearings.

The canopy and chassis were manufactured by Carrimore Six Wheelers, Ltd. The general design of the set is illustrated in the drawing, Fig. 3, from which it will be noted that the cables for coupling up from the generating set to the storage batteries are carried, when not in use, upon the rear end of the canopy, the housing of which covers the radiators, while the lower part forms a chest for tools and spare parts. The generator is of the one-bearing, shunt-wound, self-excited, direct-current type, giving a normal output of 67 kW when running at a speed of 1200 r.p.m. The dynamo has been specially designed to meet the conditions of service required in a mobile charging equipment. The frame has no feet, but is supported on two substantial bars welded to each side, resting directly on the chassis of the vehicle and giving a low height of centre. The machine is self-ventilated with two pipe inlets at the commutator end, which are connected by short lengths of trunking to the sides of the vehicle, so that a supply of clean cooling air is obtained from a point well away from the heat of the engine. The air discharge is downwards at the driving end. Terminals are arranged on the top of the frame so as to be easily accessible from the interior of the truck.

The generator has a current capacity of 1000 ampères, at any voltage from 24 to 80. The voltage range is obtained partly by varying the speed of the engine from 550 to 1200 r.p.m., and partly by a rheostat in the shunt field. The output thus varies with the speed, being 24 kW at the lowest speed and 80 kW at the highest. Hence, the engine is always running at about constant torque. The armature carries a self-equalised lap winding, giving the high degree of equalisation desirable in heavy current low-voltage machines, and designed to reduce the commutation troubles to a minimum.

When running at the highest speed and voltage there is a considerable margin in the field rheostat, and if all this were cut out an excessive voltage would be obtained, resulting in overheating and possible breakdown of the field windings or rheostat. To prevent this, a fuse with a high resistance in parallel is arranged in the field circuit, so that if the field current reaches a dangerous figure, the fuse will blow and the high resistance will reduce the current to a safe value.

The switchboard is equipped with a 1000-ampère automatic single-pole Salford circuit breaker, a double-pole knife switch, 6in. diameter voltmeter and ammeter, the latter being provided with two scales to read from 0 to 750 and 0 to 1500 ampères, together with fuses and switches for controlling the electric lights provided in the power compartment. Each switchboard bus-bar is coupled up to three conductor couplings securely fixed to the side of the canopy, to which the flexible cables are coupled for transmitting the current from the generator to the telephone exchange. Both the voltmeter and ammeter are spring mounted to prevent damage due to the transmission of road shocks during transit. From Fig. 3 it will be seen that the engine and electrical controls are arranged at a central position adjacent to the switchboard, so that the entire set is under the control of the operator for adjusting the voltage output before closing the circuit breaker connecting up to the storage battery, provision being made by means of a change-over switch to read independently the voltages of the storage battery and generator on the voltmeter scale.



The Engineer

FIG. 2—67 kW MOBILE POWER SET

Careful consideration was given to the design of the cables in order to obtain the necessary degree of flexibility and to facilitate handling. It was ultimately decided to provide a conductor consisting of 940 tinned copper wires of 0·029in. diameter with vulcanised Indiarubber covering. Each unit carries eight 60ft. lengths of cable, each length being fitted with screw couplings capable of carrying 600 ampères. The couplings are of the plug and socket type supplied by Simmons and Stokes, Ltd. To prevent damage to the contacts, light-screwed covers are provided, as shown in Fig. 5.

To lessen the noise set up during normal running of the generating set, the canopy is divided into two compartments, the partition being arranged adjacent to the engine coupling and the engine compartment lined with Celotex slabs of the acoustic type.

The design of the engine follows generally the lines of the Beardmore high-speed oil engines which are at work in rail traction service and other fields, and which have been fully described in previous issues, with the exception of the introduction of minor modifications required by this particular application. The cylinders are 4in. by 6in., with a speed range between 600 and 1200 r.p.m. Governor control is provided to maintain constant engine torque over the entire speed range, this precautionary measure being introduced to guard against the possibility of the engine overspeeding in the event of the circuit breaker being opened through a possible failure in the transmission system.

Special interest attaches to the type of Beardmore fuel pump which the makers have fitted to this engine. It is shown in section in Fig. 4.

The main plunger excentric shaft A is driven from the inlet cam shaft gear wheel, through a two-to-one gear ratio, and therefore runs at engine speed. As the engine operates on the four-stroke cycle, there is only one firing stroke in the two revolutions. In order to attain this, each pump plunger B delivers fuel to two cylinders on alternate strokes, this being obtained by the use of a switch valve C which reciprocates at half engine speed, and is accordingly on its top and bottom dead centres during consecutive strokes of the main plunger, the fuel charge being thus directed to alternate cylinders.

The measurement of fuel and its period of injection is governed by the control valve D, which reciprocates at engine speed and in phase with the main plunger. This valve is formed with two reduced diameters on it, these forming annular oilways between the valve and its bushing. The upper edge of the seal between these oilways is generated in the form of a left-hand helix of small pitch, while the lower edge is generated in the form of a left-hand helix but of larger pitch than the top edge, thus forming a seal which has a varying length of face.

With the main plunger at the commencement of its suction stroke oil is drawn into the cylinder through the suction port E, and annular oilways of the control valve. As the control valve descends the centre seal blanks off the suction port, but overrunning the port allows fuel to be drawn again into the pump cylinder through the control valve upper annular oilway. The discharge stroke of the main plunger then commences and the control valve moves upwards. During the first portion of the stroke, oil is discharged back into the suction main F, *viâ* the suction port and upper annular oilway of the control valve, until the centre seal top helical edge cuts off communication with the suction side, when delivery begins. The control valve still running upwards sooner or later, depending on the load, uncovers the suction port with its lower helical edge, thus releasing the pressure and allowing the oil remaining in the chamber to be discharged into the suction side of the pump.

FIG. 4—SECTION THROUGH FUEL PUMP

It will be seen that the injection period occurs when the main plunger is approximately in the middle of its stroke, and therefore travelling at maximum velocity, the control valve being also at its maximum velocity when the centre seal is in action. A very rapid injection is thus obtained. Owing to the upper edge of the centre seal on the control valve being in the form of a helix, the commencement of injection occurs at different points under varying loads,

and the period of injection is either long or short, depending on the position of the helical lower edge of the centre seal relative to the suction port. This position is controlled by the governor. In order to prevent detonation at low speed the control valve can be moved downwards in its relation to the main plunger, thus delaying the injection period. This motion is controlled by the governor speed control mechanism.

A combined radiator of the spiral tube type is mounted upon the platform at the rear of the generating set, one section, designed to dissipate 3900 B.Th.U. per minute of heat from the cylinder jacket cooling water, and the other section to dissipate 500 B.Th.U. per minute of heat from the lubricating oil, when working with an atmospheric temperature of 80 deg. Fah. The cooling air is circulated through the radiator by a fan driven by a roller chain from a sprocket wheel carried upon the extension of the generator armature shaft.

Fuel oil is stored in a circular mild steel tank with a capacity of approximately 50 gallons secured to the front end of the canopy. The storage tank is divided into two compartments, this being in itself a precautionary measure to permit of the engine being started on standard fuel oil, such as Anglo-Persian or Shell-Mex Diesel oil, and being run on heavier grade oils which are usually readily available in the event of failure to obtain local supplies of ordinary fuel oil. The fuel tank is filled by the provision of a semi-rotary type hand pump, the fuel being passed through filters upon delivery to the fuel tank.

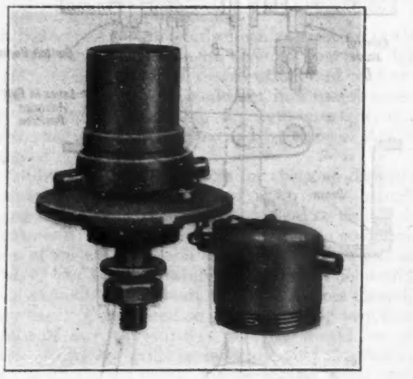

FIG. 5—CABLE COUPLING

The engine is started by a Coventry Victor air-cooled petrol engine, the power of which is transmitted through a roller chain to a lay shaft carrying a frictional bobbin to engage into "V" grooves cut on to the periphery of the main engine fly-wheel.

Each engine was given a six-hour duration test before despatch, and developed 103 H.P. when running at a speed of 1200 r.p.m., the average fuel consumption being 0·43 lb. per horse-power hour and the lubricating oil consumption 0·01 lb. per horse-power-hour. The temperature of the cooling water was maintained at 127 deg. Fah., and the lubricating oil temperature at 118 deg. Fah.; while a variable output test was carried out to demonstrate that the generator was capable of giving the outputs referred to herein.

The total weight of the unit complete with fuel oil, lubricating oil and water, tools and spare parts, is 8·25 tons, which at the maximum horse-power of 110 is equivalent to 160 lb. per horse-power.

ENGINEERING IN THE SERVICE OF CHEMICAL RESEARCH.

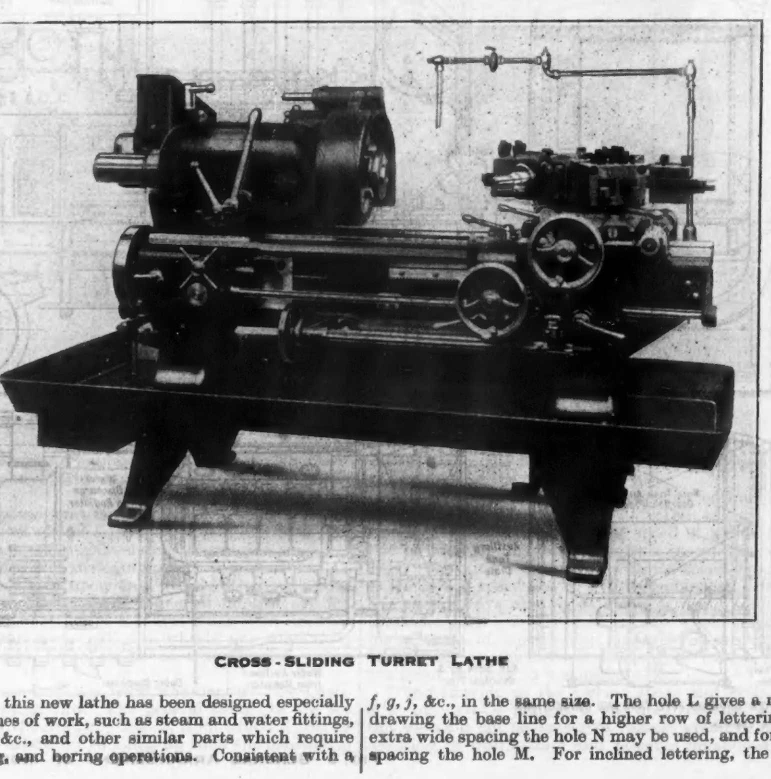
PROFESSOR G. T. MORGAN, Director of Chemical Research under the Department of Scientific and Industrial Research, lectured before the Institution of Chemical Engineers on Friday evening, October 27th, on "Engineering in the Service of Chemical Research." Professor Morgan is one of the foremost exponents of the comparatively new science of high-pressure chemistry, in which the glass test-tubes of the chemist are replaced by very strong steel containers in which many chemical reactions, not occurring under ordinary conditions, take place under the compulsion of increased pressure and high temperature. Professor Morgan showed specimens of earlier autoclaves, as these metal test-tubes are called, made from naval and military shells, and still earlier examples made from the solid steel of the shaft of a marine engine. He described his successes at the Chemical Research Laboratory with pressures of 200 atmospheres at 450 deg. Cent., in inducing methyl alcohol and carbon monoxide to combine in the synthetic production of acetic acid, and in producing by equally direct methods many other chemicals of industrial importance. He showed also how troubles arising from the excessive corrosion of steel found at these high pressures and temperatures had suggested new means for examining the corrosion-resisting properties of steels and new steel alloys, and for devising accelerated corrosion tests by which the life of a particular steel under various conditions of service might be assessed. Apparatus has now been devised at the Chemical Research Laboratory by which experiments can be carried out under 3000 times atmospheric pressure, *i.e.*, at a pressure of about 20 tons per square inch. The pressure-resisting parts for this plant were made from Sheffield nickel-chromium-molybdenum heat-treated steel. The plant is enclosed within steel screens so arranged that the various controls are operated from outside this protection. At the other extreme constituents of coal tars difficult of separation are being obtained at the Laboratory by distillation of the tar at very low pressure—of the order of one-thousand-millionth of an atmosphere—in a plant in which the cold condensation surface is placed so near the substance being distilled that the molecules of the substance it is desired to isolate escape direct to the condensing surface without contamination by others. Professor Morgan also described the plant by which similar separations were being carried out by filtration at a temperature of 80 deg. Cent. below zero.

SIXTY YEARS AGO.

A FEW years ago two crowded suburban trains in the London area, proceeding on parallel lines, "slightly grazed" each other. There was some splintering of woodwork and a brick wall was partially demolished. No one, however, was injured or killed, and because of that fact the accident was dismissed—in unofficial quarters, at least—as of little moment. It was evident, however, that in the features of the mishap there were all the elements for a disaster of the first magnitude. Only by the fortuity of circumstances did it escape from that category. It is perhaps a human failing to judge the gravity of a railway or other accident by the number of victims which it claims. Clearly, however—in official quarters, at least—the gravity of an accident should be assessed not so much by the actual roll of casualties as by the deaths and injuries which it might have caused, but for some split second or other freak of chance such as attends most accidents, and upon the occurrence of which no one has any right to rely. It was doubtlessly with a similar thought in our minds that in our issue of November 7th, 1873, we published a list of the railway "disasters" which had occurred on British lines during the preceding month. There were thirty-five of them. On one day alone there were five. Most of them were, no doubt, considered by the general public as trifling, but, as we pointed out, each just escaped being "terribly fatal." At Shipton, on the North-Eastern, for example, a broken axle in a goods train caused several trucks and their contents to be thrown on to the down line, along which the Newcastle mail train had passed only half a minute before. At Goring, on the Great Western, disaster was avoided by an exact reversal of the circumstances at Shipton. Two goods trains collided and some of the vehicles were thrown off the line, but not on to the line along which a mail train passed immediately afterwards. On the North-Eastern, and next day on the South Devon, flocks of sheep strayed on to the lines. In both cases there was slaughter among the sheep, but the trains remained on the rails. Both mishaps were probably scarcely noticed in the daily Press, but exactly a month previously a bullock which strayed on to the South-Western line near Guildford caused a derailment and smash, and the deaths of three passengers. That it required even less than the body of a bullock to derail a train was demonstrated by another accident included in our list. At Euston two carriages left the rails and ended their career by smashing their sides against the edge of a platform. They left the rails because an unfortunate policeman had tried to cross the line in front of the train. The mail train from Scotland to Euston was on the point of starting when it was discovered that the bolts fixing the tire to one of the engine wheels were broken. It was probably considered merely as an incident, but a fortnight later the tire of a fish truck wheel came off on the Great Northern near York, and the truck left the line. A double accident on the South Leicestershire line seems to have escaped being "terribly fatal" by the incidence of doubly fortuitous circumstances. A Midland engine during foggy weather collided, while shunting, with a goods train. Subsequently, a Midland mail train ran into the *débris*. Probably further mishap was avoided by the extra caution with which other trains were proceeding because of the fog. There was no actual loss of life, because it so happened that there were no passengers in the mail train.

Cross-Sliding Turret Lathe.

THE small cross-sliding turret lathe illustrated by the accompanying engraving is a new production of Alfred Herbert, Ltd., and is known as the No. 5. The makers suggest that many firms using centre lathes for machining work in small quantities could perform the task more rapidly and efficiently on a simple hexagon turret lathe.



CROSS-SLIDING TURRET LATHE

Consequently, this new lathe has been designed especially for small batches of work, such as steam and water fittings, valve bodies, &c., and other similar parts which require turning, facing, and boring operations. Consistent with a high standard of performance, such that the machine can compete with more elaborate and expensive turret lathes, its design has been kept as simple as possible. All machining operations are carried out by tools held in a hexagon turret, which is provided with automatic longitudinal and transverse motions. Changes of the rate of feed are effected by the operation of a finger controlled pilot wheel on the feed box, and the feeds obtained in revolutions per inch are indicated by large figures on the dial. Bed covers of the usual Herbert design are attached to the left-hand side of the saddle.

Manormus Drawing Instrument.

A NEW drawing instrument, known as the "Manormus," has been submitted to us for our inspection and trial by Mr. H. Castan, 27, Torrington-square, London, W.C.1, who informs us that arrangements are now being made for its manufacture in this country. The device, illustrated herewith, is a piece of transparent celluloid about 7in. long by 3¼in. wide, with one end at right angles and the other at 75 deg. to the lower edge. The face is perforated with a number of holes arranged for the most part in rows parallel with the 75 deg. edge. These holes are accurately drilled and countersunk on the upper face so as to permit a sharp pointed pencil to be inserted through any one of them.

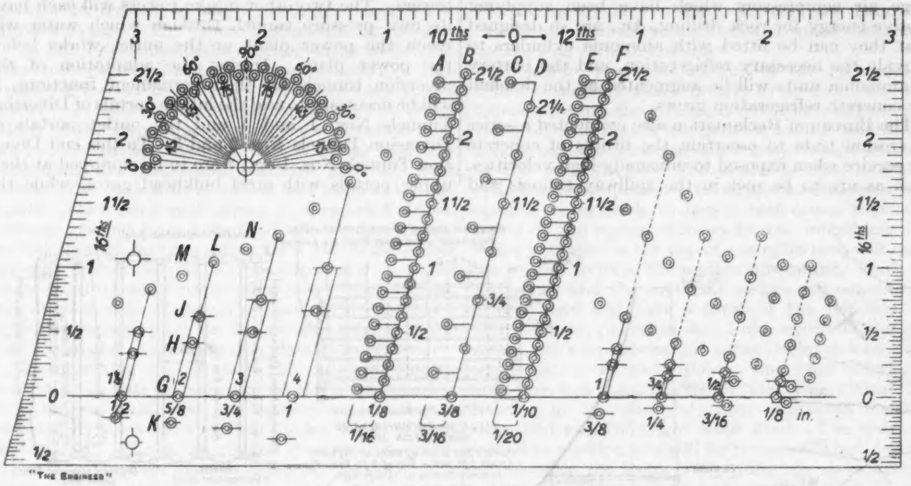
The manner of using the instrument will be described with reference to the row of holes marked D. With the lower edge of the instrument resting against the edge of a tee-square, the tee-square is held steady with the left hand and the point of a pencil is inserted through the lowest hole of the row. With a little pressure applied to the device by the disengaged fingers of the right hand, the pencil is moved to the right or left. Guided by the device the pencil point traces out a straight line on the paper beneath. The pencil point is then moved into the next hole and a second line is drawn and so on, the lines being drawn for preference alternately from right to left, and from left to right. The result is a series of parallel lines accurately spaced at ¼in. apart. If the row of holes marked C is used in conjunction with those marked D, a series of lines $^{3}/_{16}$in. apart will be obtained. Similarly, the two rows B and A give lines at ⅛in. and $^{1}/_{16}$in. apart while rows F and E give lines at $^{1}/_{10}$in. and $^{1}/_{20}$in. apart. The use of the device in this way provides a ready means of drawing quickly and accurately cross-hatching lines at various spacings. By inclining the tee-square the hatching may be made diagonal, and by a suitable selection of the holes it may be made with alternately wide and close spacings. Since the holes are marked as shown, the rows A–F provide a quick and accurate means of drawing a single line parallel to a given line at any distance up to 2½in. provided the distance apart is a multiple of $^{1}/_{20}$in. or $^{1}/_{16}$in.

A series of lines having been drawn in this manner in one direction, the device may be turned through 90 deg. with the aid of a set square and a similar series drawn across the first. The result will be a series of squares or oblongs according as the same or a different row of holes is used. In this way squared paper for the plotting of curves or frames for tabular matter can be readily produced.

Again, with a drawing pin inserted in the lowest hole of any of the rows A–F, circles of various diameters can be drawn by swinging the device round the drawing pin as centre, while the pencil point is inserted in the hole at the required radius. An accurate series of concentric circles can be drawn in the same manner.

Consider next the holes G H J. With their aid three parallel lines may be drawn. The two outer lines will be ⅜in. apart. If they are used as guide lines for capital letters, then the inner line drawn by the pencil when in the hole H will be at the correct height for small letters matching ⅜in. capitals. The line drawn by the hole K will provide a guide line for the tails of such letters as *f*, *g*, *j*, &c., in the same size. The hole L gives a means of drawing the base line for a higher row of lettering. For extra wide spacing the hole N may be used, and for narrow spacing the hole M. For inclined lettering, the 75 deg.

edge of the device provides the means of drawing guiding lines for the strokes, while for vertical lettering the opposite end may similarly be used. The two parallel lines joining the holes G J indicate the desirable width for the strokes of the letters. In this case it is implied that a No. 2 lettering pen, or one giving a stroke 2 mm. wide, should be used. It will be observed that to the right and the left of the rows A–F rows are provided to facilitate lettering having a height of from ⅛in. up to 1in.



THE MANORMUS DRAWING INSTRUMENT

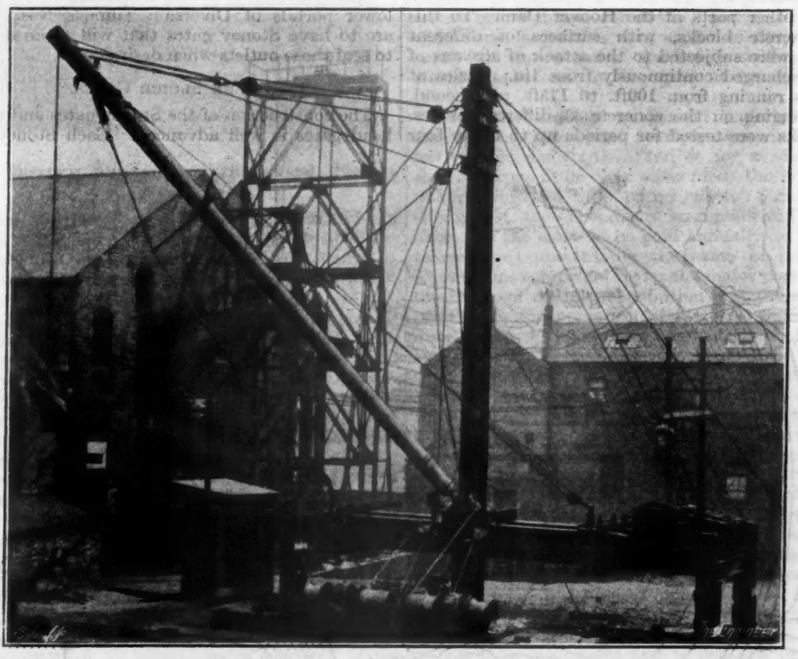
In the case of the rows for the smaller sizes of lettering, additional holes are provided to enable a number of base lines to be drawn at one setting of the tee-square.

A protractor with holes corresponding to angular intervals of 5 deg. occupies the upper left-hand corner of the device, while round three of its edges are scales of inches divided into $^1/_{32}$nds, $^1/_{16}$ths, $^1/_{12}$ths, and $^1/_{10}$ths. For normal use by draughtsmen the device has a plain lower edge, but for artists, sign writers, and others, working at easels, it is found convenient to have a small metal upstanding angle attached along the lower edge.

We have tried the instrument and find it both useful and easy to operate, and to be a pleasant aid in drawing.

Combined Winch and Derrick.

In an article which appeared in The Engineer of November 18th, 1932, we described and illustrated a working model of a combined winch and derrick system manufactured and developed by Clarke, Chapman and Co., Ltd., of Gateshead, by arrangement with the inventor, Mr. George T. MacFarlane, known as the Clarke Chapman MacFarlane patented lifting slewing and topping winch, and derrick system. By means of a three-drum winch, the combined operations of the derrick can be controlled by one man. In the accompanying engraving we illustrate one of these winches, which has recently been built and tested for a vessel now under construction at a Scottish shipyard.



COMBINED WINCH AND DERRICK SYSTEM

The winch is designed to lift 3 tons at 100ft. per minute, 1½ tons at 200ft. per minute, and to operate with a light hook at 400ft. per minute. A hoisting motor of 25 B.H.P., a derricking motor of 20 B.H.P., and a slewing motor of 12½ B.H.P. are provided, all the motions being independently driven by means of worm gear. The controls comprise three vertical handles mounted on one combined master control box, which are shown at the back of the winch barrels in the illustration. A foot brake is provided on the hoisting motion and magnetic brakes are provided on the hoisting, derricking and slewing motions, and a magnetic brake release handle is fitted on the hoisting motion.

By means of the winch a 7½-ton derrick is operated with three-to-one purchase blocks, also a 3-ton load on single fall. Under the test conditions the maximum radius of the derrick was 30ft. and the minimum radius 16ft., the maximum reach of the derrick being 24ft. on each side of the centre line of the ship. With the MacFarlane arrangement, the winchman has all the controls within reach, and can lower the hook, adjust the height of the derrick by the topping lift to the actual position of the load, wind in, swing the derrick outboard or inboard, and adjust the height again before lowering to the required spot. There is no slack in the gear, whether the ship is on an even keel or in a heavy sea, and rolling has little effect on the derrick. The makers claim that all the advantages of a double winch and derricks are obtained without the attendant disadvantages such as the bumping of a load and the rearrangement of the gear which is necessary when loading on different sides of the ship.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

LEAD TRAPS.

No. 504—1933. This new standard provides for traps for use with baths, lavatory basins, sinks, bidets, &c. British manufacturers whose practice it has been to produce traps in accordance with the requirements of the various local authorities have suffered in the past owing to the importation of inferior foreign traps which were neither of the same weight nor measurement and with sometimes very little water seal. This has emphasised the necessity for standardisation on a national scale, and this specification should have the favourable effect of placing competition on an equitable basis. The specification lays down the quality requirements of the material from which the traps are made. It fixes the dimensions, weights, length of inlet and outlet, and the depth of seal. An interesting piece of standardisation is the design of the screw caps. These are fitted to 1in., 1¼in., 1½in., and 2in. diameter traps, and are required to be of hot-pressed brass.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

WATER LOWERING IN QUICKSANDS.

Sir,—In the discussion which followed the reading of a paper on the above subject at a London meeting of the French Society of Civil Engineers, on October 24th, nearly all the civil engineers who spoke lavished compliments on the German "system" of lowering the water level in water-bearing strata and described as novel the method of pumping water from a bore-hole.

The general impression left by these speakers was that German brains and experience had solved a problem which British dock engineers had been afraid to tackle. All the speakers flattered with childlike indiscrimination the "system" and not one referred to the most important feature—the bore-hole pump driven by a submersible electric motor—which had made the "system" easy of application.

There is, however, nothing novel or particularly German in a system of lowering the water level in water-bearing strata by pumping from a bore-hole, as any waterworks engineer could have informed the meeting; nor do the submersible motors driving bore-hole pumps originate from Germany, but rather have been developed in Germany from British ideas and inventions.

The first submersible motor pump was successfully made in England under British patents before the war, and since then they have been greatly improved and developed for various services.

Several Continental countries have adopted British designs and ideas and have for some years past paid royalties to the British patentee of submersible bore-hole pumps accordingly, and whose patents were upheld against strong opposition in Germany.

Had the engineers called for British pumps for such service they could have been supplied without the necessity of going to Germany, or had they understood what system was required in the application of such pumps.

The real novelty appeared in the sudden awakening of dock engineers and contractors to a realisation of possibilities with bore-hole pumps that are now becoming common practice among waterworks engineers. But the deplorable aspect of the affair is that it required the blandishments of German salesmanship to overcome their timidity—the pretext for the introduction of German submersible pumps being concealed by the courage displayed in utilising a new "system." Any waterworks engineer with experience of pumping machinery could have told these gentlemen that the same duty can be obtained with a British patent, British designed and British manufactured submersible bore-hole pump, and that far from German claims being unique, the same, if not better, results could have been obtained by the employment of British resources of brain and manufacture.

If civil engineers and contractors in this country do not exhibit some courage in the attempts being made to encourage home industries, they must be made to realise the enormity of their unpatriotic timidity.

T. L. Reed Cooper.

London, October 31st.

CONTRACTS.

The Port of London Authority has placed a contract for a period of six months with the British Thomson-Houston Company, Ltd., for the whole of its electric lamp requirements.

The Brush Electrical Engineering Company, Ltd., has secured the order for two 11,000-kVA transformers from Kettering U.D.C., to supply Stewarts and Lloyds' new iron and steel works at Corby. The two units will each be 11,000 kVA, three-phase, 50 cycles, 33/11 kV, fitted with remote control "on-load" tap-changing gear.

W. H. Allen, Sons and Co., Ltd., Queen's Engineering Works, Bedford, announce that they have just been favoured with the order for two three-cylinder 100 B.H.P. airless injection oil engines running at a speed of 500 r.p.m., to be installed in a twin-screw trawler operating from Lowestoft. This vessel will be the highest-powered Diesel-engined vessel of its type sailing from Lowestoft Harbour. The engines will be of exactly the same type as those installed in "Dusky Queen," "Boy Clifford," "Helping Hand," &c.

LAUNCHES AND TRIAL TRIPS.

Malaita, single-screw motor ship; built by Barclay, Curle and Co., Ltd., to the order of Burn, Philp and Co., Ltd., Sydney; dimensions, 325ft. by 47ft. by 23ft. 6in.; to carry passengers and cargo. Oil engines, B. and W. Diesel type; constructed by Messrs. Kincaid and Co., Greenock; trial trip, October 14th.

Redwing, harbour service vessel; built by J. Samuel White and Co., Ltd., to the order of the Admiralty for H.M. Dockyard, Devonport; dimensions, 102ft. by 25ft. by 11ft.; launch, October 19th.

Central Flying School, Royal Air Force.—Marshal of the Royal Air Force Lord Trenchard will preside at the "coming-of-age" dinner of the Central Flying School, Royal Air Force, which will be held at the May Fair Hotel, London, on Friday, November 24th. The dinner has been arranged in order to celebrate the twenty-first anniversary of the formation of the School at Upavon in 1912. The School is now stationed at Wittering, Northants. The Organising Committee has been unable to get into touch with many officers of the Royal Flying Corps, Royal Naval Air Service, and Royal Air Force who are eligible to attend, and desire it to be known that the qualifications for attendance are as follows:—All officers who were on the staff of the C.F.S. or who attended courses at the C.F.S. before August 4th, 1914; all officers of the rank of captain and upwards who were on the staff of the C.F.S. during the war; all officers who have been on the staff of the C.F.S. since the war period, *i.e.*, since January 1st, 1920. Officers coming within these categories who wish to be present at the dinner should communicate with the Secretary, C.F.S. Dinner Committee, Central Flying School, Wittering, near Peterborough.

The Hoover Dam on the Colorado River.

No. III.

(Concluded from page 403, October 27th.)

In June of this year the Bureau of Reclamation awarded to four large western cement companies a contract for 400,000 barrels of a special low-heat cement, at a price of 1·40 dollars per barrel. These companies have collaborated with the Bureau of Reclamation in developing types of low-heat cement which have been exhaustively tested. All told, about 100 different cements were subjected to tests, and considerably in excess of 15,000 specimens were examined. The approved low-heat cement is to be used in the main structure of the dam. It represents the outcome of efforts to find means of reducing the evolution of heat in great masses of concrete caused by the hydration of the cement while the mixture is hardening. As is well known, this heat causes pronounced volumetric changes in the body of the concrete, and as the mass cools and contracts the resulting stresses frequently cause more or less serious fractures. There is reason to believe that the employment of low-heat cement will prove of outstanding practical importance, not only in the case of the Hoover Dam, but wherever great masses of concrete are concerned.

Low-heat Concretes.

The three most promising of the low-heat cements evolved by the joint labours of the experts in the employ of the Government and the cement companies were thoroughly tested for temperature rise, volume changes, and elastic and plastic properties in the laboratories of the Bureau of Reclamation at Denver, Colo. Among the equipment provided for the purpose was a 4,000,000 lb. hydraulic compression-testing machine capable of handling test cylinders of concrete measuring 3ft. by 6ft. The employment of low-heat cement will not alter the prescribed procedure involving the pouring of the dam in columnar sections or block units averaging 50ft. by 50ft. in horizontal cross section, and having circumferential construction joints in addition to the usual radial contraction joints—see Fig. 12. The joints are to be painted and then grouted after the concrete has set and sufficiently cooled. Each lift or pour is limited to a depth of 5ft. in seventy-two hours. After the concrete has set for six days, an artificial cooling system, making use of 2in. pipes imbedded in the concrete, can be brought into action to hasten further cooling—see Fig. 13. All told, there will be 800,000 linear feet of piping, arranged in lines 10ft. apart. The circulatory system will distribute 2100 gallons of chilled water per minute through these pipes. The fluid will have a temperature low enough to reduce the temperature of each unit concrete mass to about 72 deg. Fah. in the course of 2·4 months in the summer time, when the maximum temperature of the concrete, because of the high atmospheric temperture, will be about 134 deg. Fah. A number of the large air compressors which have been supplying motive energy for rock drilling, &c., are so designed that they can be fitted with ammonia cylinders to provide the necessary refrigeration, and the battery of ammonia units will be augmented as the demand for concrete refrigeration grows.

The Bureau of Reclamation also conducted a series of erosion tests to ascertain the fitness of concrete for service when exposed to unusually high velocities, such as are to be met in the spillway tunnels and in some other parts of the Hoover Dam. To this end, concrete blocks, with surfaces of different textures, were subjected to the attack of streams of water discharged continuously from 1in. nozzles at velocities ranging from 100ft. to 175ft. per second, and impinging on the concrete at different angles. The blocks were tested for periods up to thirty-four days. The experiments disclosed that it would be practicable to construct concrete linings for the spillway tunnels, &c., capable of resisting erosion with the water at the velocities mentioned, but it was incidentally proved that the concrete surfaces must be smooth and carefully aligned.

SECTION OF DAM
SHOWING TYPICAL ARRANGEMENT OF COOLING PIPES

Fig. 13—Arrangement of Artificial Cooling System

As indicated in Fig. 1 *ante*, the four big diversion tunnels are to serve as regular operating features of the dam. Diversion Tunnels Nos. 1 and 4 will become spillway tunnels for so much of their lengths as reach downstream from their connections with the spillways. Diversion Tunnels Nos. 2 and 3 will become pressure tunnels linked with two of the intake towers. The two other intake towers will each have its own pressure tunnel, through which water will reach the power plant or the outlet works below the power plant. During the adaptation of the diversion tunnels for their permanent functions, it will be necessary to seal the intake portals of Diversion Tunnels Nos. 1 and 4 and the outlet portals of Diversion Tunnels Nos. 2 and 3. To this end Diversion Tunnels Nos. 1 and 4 are to be equipped at their upper portals with steel bulkhead gates, while the lower portals of Diversion Tunnels Nos. 2 and 3 are to have Stoney gates that will make it possible to seal those outlets when desirable.

The Sluice Gates.

The construction of the Stoney gates and the bulkhead gates is well advanced. Each Stoney gate is 50ft. wide and 35ft. high, and is made up of seven horizontal structural steel girders, unequally spaced from 3ft. 3in. at the bottom to 10ft. 5in. at the top of the gate. The horizontal girders connect with vertical girders at the sides and are covered on the outer or downstream face with steel skin plates $\frac{3}{16}$in. in thickness. The steel cross girders are 51ft. 6in. long, 6ft. 2in. wide at the centre, and 3ft. 7½in. at the vertical girder connections. The vertical girders are approximately 37ft. long and 3ft. 7½in. in width. Two steel ear-plates extend beyond the upper ends of the vertical girders to form connections for the operating hoist chains. Twenty vertical latticework trusses, equally spaced, are employed to stiffen the gate. The concrete structure for the gate —see Fig. 14—contains the counterweight wells; the gate recesses, equipped with guide plates; a rail-protected inspection platform, 56ft. above the tunnel invert; a hoist house extending across the entire width of the structure, with its floor elevation 99ft. above the tunnel invert; and a spiral stairway connecting the inspection platform and the hoist house. The gate is to be raised and lowered by two hoists. Each hoist will consist of a sprocket driven through gearing from a shaft which, in turn, is connected through worm gearing to a 10½ horse-power slip-ring induction motor. A water seal is to be maintained by seal pipes of 3½in. heavy brass tubing, one on each side of the gate; each seal pipe bears against a bronze plate on the outside corner of the gate recess and against the skin plate of the gate.

The operating chains, each 82ft. 10in. in length, run from the gate up and around the hoist sprocket to counterweights, and are constructed of bronze pins 5in. in diameter, and 19in. by 9in. links, of high carbon steel. The motor control consists of a drum-type controller with limit switches for the upper and lower ends of the gate travel. Each of the two counterweights is composed of a steel hanger and nine 11,200 lb. precast concrete blocks. The suspended weight of each Stoney gate and chain, with the gate down, is approximately 261,000 lb., and that of the counterweights and chains is 215,500 lb. The normal hoisting speed is 0·891ft. per minute, and the total lift is 58ft.

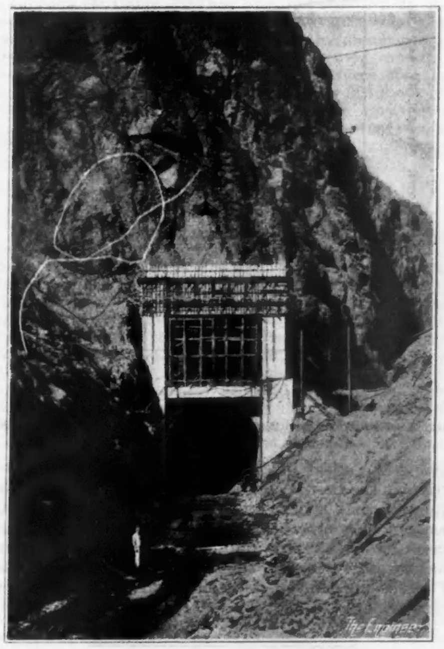

FIG. 14—OUTLET PORTAL OF DIVERSION TUNNEL No. 2

Each of the bulkhead gates at the inlet portals of Tunnels Nos. 1 and 4 is 50ft. wide and 50ft. high. These gates are of much heavier construction than the Stoney gates, because they are designed to withstand a hydrostatic head of 295ft. Except for testing purposes, it is not contemplated that the bulkhead gates will be lifted after they have once been lowered. Therefore, the operating mechanisms for the bulkhead gates have been designed for controlled and sealed closure rather than for recurrent operation, as in the case of the Stoney gates. Each bulkhead gate is made up of nineteen horizontal structural steel girders connected to a vertical girder on each side. The horizontal cross girders are 55ft. 3in. long, and 12ft. 6½in. wide. The vertical girders are 50ft. 5½in. long and 10ft. 6¾in. wide. Connection to the stems of hydraulic cylinders, which control the gate movement, is obtained by extensions of the web plates of the vertical girders. On the upstream side of each gate is a cover plate unit 47ft. wide and 50ft. 6in. high, made of 1in. plates riveted to cross girders, and on the exterior face of this unit are nineteen ⅞in. plates—one for each cross girder. Skin-plate units, 1¼in. thick, are placed between the cross girders at 10ft. 7½in. from the upstream face of the gate. The concrete structure for each gate is 119ft. high, and contains structural steel guides, brackets, roller tracks embedded in the gate recesses, and cast steel stationary wedges fastened to the embedded brackets. An assembly recess is provided above each tunnel entrance, reaching from 56ft. to 119ft. above the tunnel invert, and a foundation and platform are provided above the assembly recess for two large hydraulic cylinders and a control board. The hydraulic cylinders are steel castings 69ft. in height and 7ft. 7in. inside diameter. The maximum piston stroke is 62ft. 5in. Six roller trains of caterpillar type are fitted on each side of the gate to reduce friction. The carriages are attached to cross girders, and the rollers travel on a high carbon steel seat plate set in the concrete structure. The rollers are 14½in. long by 8in. in diameter, and are made of a chilled cast iron alloy, with axles of rolled manganese bronze pins 1¾in. in diameter.

To ensure the tight closure of the gate and to transmit water pressure directly to the gate structure, thereby freeing the rollers, a movable wedge is provided on each side of the gate for its full height, and makes contact with the stationary wedge fastened to the gate frame. The stems of the hydraulic cylinders are connected to toggle mechanisms that operate the movable wedges in such a way that overtravel of the stems, induced by the introduction of water pressure on the top of the cylinders, will cause the toggles to force the wedges downward. Both the stationary and the movable wedges are constructed of cast steel and have a taper of ¾in. per foot. A corner filler is placed in each lower corner of the gate recess to keep rocks or other obstructions from accumulating at these points, and thus interfering with the complete closing of the gate. This filler consists in the main of three reinforced concrete slabs laid on a filling of clean sand. The slabs are locked in position and will be removed, when desired, by releasing the locks and pulling the slabs upward and outward from their seats with the aid of wire ropes attached to the slabs. The sand will then be driven out of the recess by two jet pipes. Cooling sprays will reduce the temperature of the metal in the gate to approximate equality with that of the river water before the gate is lowered. The spray system, in each case, is made up of three 1¼in. pipe lines; one line is placed horizontally above the gate, with the jet set to spray the gate on the tunnel side, and the two other lines run vertically within the gate, between the upstream cover plate and the skin plate. It is estimated that the total amount of water required for lowering the gate will be about 98,000 gallons, and that the maximum supply required at any time will be 660 gallons per minute. The cylinders can be filled in seventy-five minutes and the gates lowered in forty-five minutes. Each gate will be sealed in position by a rubber and a bronze seal at the downstream side and at the top of the gate, and by a babbitted seal at the base. Each bulkhead gate weighs 2,180,000 lb,. while the weight of a gate, hydraulic cylinders, wedges, and steel frame totals 3,065,000 lb.

Exclusive of erection charges, the cost of the two Stoney gates, with their frames and hoists, was about 64,000 dollars, while the bulkhead gates, with their related features, involved an outlay of about 266,000 dollars. The materials and parts of each bulkhead gate required the services of forty-two railway cars to transport them to Black Canyon.

PERSONNEL.

The numerical peak of employment was reached on January 1st of the present year, when a total of 3882 men were directly engaged on the different phases of the work at and adjacent to the dam site. From now onwards this army will diminish gradually, but the proportion of expert workers will increase because of the higher order of work that will be in progress in many departments of the undertaking. While various other parts of the task are under way, very few of them have advanced beyond their initial stages, and, such being the case, we shall not refer to them until they have proceeded far enough to make them noteworthy.

The Institution of Electrical Engineers.

THE PRESIDENTIAL ADDRESS.

THE present position of power cable manufacture and the prospects of its future development formed the outstanding subject of Mr. P. V. Hunter's Presidential Address, delivered before the Institution of Electrical Engineers on Thursday, October 26th. Attention was also paid, however, to matters of current interest, including the proposal that small distribution systems should be absorbed by the larger undertakings. While giving support to this idea, Mr. Hunter admitted that it was difficult to show that the present arrangement had resulted in any appreciable addition to the cost of electricity. The situation, he said, was entirely different from that which existed in connection with the generation of electricity before the advent of the "grid." Under those conditions, large sums were wasted in the building of small and uneconomical generating stations, but no waste of that nature occurred in connection with distribution.

Even the smallest authorised undertakings had adopted the three-phase, four-wire system for general low-voltage distribution, and so far as distribution capital expenditure was concerned, the size of the undertaking had little or no effect. Similarly, the energy lost, the expenditure on repairs and maintenance, and the sums to be paid annually for rates and taxes were substantially the same in both cases. Those items comprised by far the major portion of the total annual cost of distribution and the economies possible in the operation of large, as against small distribution systems were confined to management expenses which might generally be assumed to be less than 20 per cent. of the total cost. But these considerations were not put forward as an argument against the consolidation of distribution areas. The broad view that small distribution systems should be absorbed in the larger organisations was, in Mr. Hunter's opinion, undoubtedly correct, although he made little attempt to develop the argument. It was satisfactory to realise, he explained, that where the process was delayed, there would not be an accumulation of wasteful capital which would ultimately have to be made good. The most interesting part of the address from a technical point of view was that devoted to cables, of which the following is an abstract.

It will be convenient first to consider present-day British practice in the ordinary type of solid impregnated paper cable, which is now employed for working pressures up to and including 66-kV three-phase. An outstanding fact that has been brought out by practical experience is the superior performance of the screened type of cable, as compared with the belted type when subjected in service to high working stresses in the dielectric. Two sets of graphs—Fig. 1—have therefore been prepared, showing the maximum working stress of the belted and screened types of cable for pressures up to 66 kV. For the purpose of these curves the dimensions of the British Standard Specification No. 480 have been employed where applicable, *i.e.*, for voltages up to and including 20 kV. For voltages above this limit, although there are no standards which have been adopted by the British Standards Institution, the current accepted practice of the Cable Makers' Association has been followed, which provides for a dielectric thickness of 0·325in. for 33-kV cables and 0·65in. for 66-kV cables. It is at once apparent from Fig. 1 that for no obvious reason there are considerable differences in the stresses for the different voltages. There is no technical justification for working a 0·25 square inch 11-kV screened cable at the low maximum stress of 22·5 kV per centimetre, when for the same size of conductor in a 66-kV screened cable the dielectric is subjected to the much higher stress of 42·2 kV per centimetre.

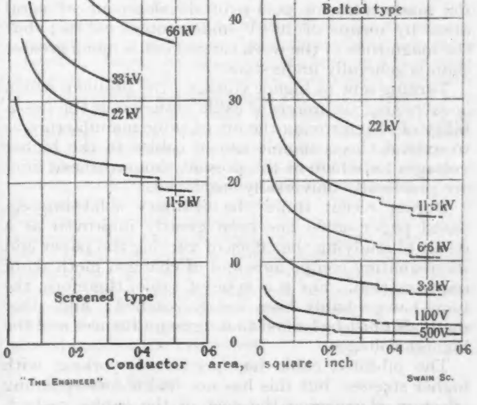

FIG. 1—MAXIMUM WORKING STRESSES OF 3-CORE CABLES

In order to see whether these higher working stresses are permissible in the lower voltage cables, two separate trials have been made, in which lengths of cable having 22-kV dimensions have been manufactured according to the methods employed in the case of 66-kV cables, and using similar materials. The resultant quality of the insulation is therefore equal to that of the 66-kV cable. The cables so made have been put to work in 33-kV systems, with satisfactory results. The maximum stress in these cables when working was 51·5 kV per centimetre, which, it will be noted from Fig. 1, is higher than that ordinarily experienced by a 66-kV cable. It may be concluded, therefore, that there is a margin for economy obtainable in the lower-voltage cables by so reducing the thickness of dielectric as to give the same working stresses as in the higher-voltage cables. Before this can be achieved, however, complete confidence must be established in commercial working at the higher stresses.

Cables are expected to have a lengthy economic life, and changes in accepted practice can be justified only by convincing evidence in favour of the alteration. Moreover, the most ardent advocate of reducing the dimensions of lower-voltage cables is apt to be discouraged when viewing the results in true economic perspective. Under the conditions in which these cables are normally laid in the streets of cities and towns, the cost of trench work is a high proportion of the total, and even a substantial reduction in the dielectric thickness of low-voltage cables has but a small effect when expressed as a percentage of the total cost of the laid cable.

There are, however, conditions in which an economy in cable manufacture would be of considerable economic value, namely, in the case of 11-kV cables for rural distribution laid across country. Under these conditions the cost of the trench work can be kept much lower, and the economies in the cost of the cable itself represent a higher proportion of the total cost. The employment of underground cables for rural work in this country is inclined to languish, partly because up to the present time engineers have been reluctant to run cables across country in the same way as they do overhead lines. There is, however, no real objection to such methods. The cable is less liable to interference and less costly to maintain than when laid in public roads.

It should also be possible to standardise a universal type of rural cable for 11-kV working, of fixed conductor size and special design, working at the stresses permitted in super-tension cables. If this were done, not only would the cable be intrinsically cheaper to manufacture, but economy would result in many directions. For instance, at the present time, owing to the multiplicity of sizes and types, the average length of 11-kV cable put through a factory on each order is less than 1 mile.

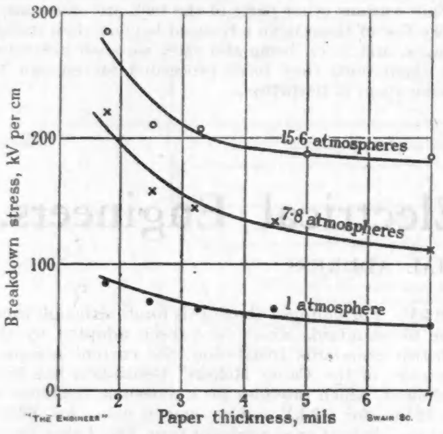

FIG. 2—RELATION BETWEEN PAPER THICKNESS AND BREAKDOWN STRESS

It is well known that in Holland there has existed for many years a policy of development of rural areas by means of 10-kV underground cables; but the magnitude of the work carried out is much greater than is generally understood.

Turning now to higher voltages, the problem which is exercising the minds of cable designers is the possibility of so improving the art of cable manufacture as to extend the economic use of cables to the higher voltages for which at the present time overhead lines are practically universally employed.

During recent times the ordinary solid impregnated paper cable has been greatly improved as a result of studying the effect of varying the paper and impregnating compounds and of changed methods of impregnation. For this type of cable, therefore, the limit has probably been nearly reached; and other methods must be looked to for great advances and the highest voltages.

The oil-filled cable has permitted working with higher stresses, but this has not had a corresponding effect in cheapening the cost of the cables as laid. Some radical departure from existing methods is therefore necessary. Physicists have not so far produced any generally accepted fundamental theory explaining the mechanism of insulation and the *modus operandi* of dielectrics under electrical stress, so that we cannot say what are the limiting possibilities.

It has long been known that the electric strength of gases increases with compression, and in a paper* read before this Institution in 1909 E. A. Watson showed the use of compressed air in reducing the dimensions of a static voltmeter. Also, in the year 1915, F. Kock described in the *Elektrotechnische Zeitschrift* the results of experiments showing the increased breakdown strength resulting from the compression of a number of materials, including transformer oil. It is not possible to make cable dielectrics exclusively of either gases or oils under compression; but, using paper as a supporting medium, both these methods have been under investigation by a number of workers.

The results obtained by submitting a solid impregnated-paper cable to compression have been published by Höchstädter, who found that by raising the compression from 1 atmosphere to 16 atmospheres the long-time breakdown strength was increased by 100 per cent. By this method a 66-kV cable is made suitable for 132 kV, which is a very considerable advance; but even this is hardly sufficient to make underground cables competitive with overhead work as regards their capital cost, after taking account of the cost of the additional equipment. The practical development by Emanueli of the oil-filled cable in the form in which it is generally used aims at controlling the internal pressures set up within the cable by changes of temperature consequent on load variations. The pressure variations permitted by his design lie within the range of 1 atmosphere minimum to about 4 atmospheres maximum. Even with this range he finds it necessary, in general, to reinforce the cable sheath, the usual practice being to provide two lead sheaths with a brass reinforcing tape enclosed between them. It wouldnot be difficult to adapt such a system to work with much higher oil pressures; for instance, a range of pressure from 4 to 7 atmospheres would involve very little modification to the construction of the cable itself, although the design of the joints and terminals would undoubtedly be rendered more difficult.

The methods of sheath reinforcement necessary to withstand the higher pressures employed in such circumstances and with the compressed gas cable referred to later have received some attention, with the surprising result that paper has been found to be the most efficient material for this purpose in circumstances under which ferrous metals may not be used. In their endeavour to produce a paper to take the place of woven fabrics in mechanical applications papermakers have successfully evolved a comparatively cheap wood pulp paper in which the breaking strain is 18,000 lb. per square inch, thereby rendering it more economic than a non-ferrous metal. There is no objection to the use of paper when it is enclosed and hermetically sealed in the annular space between two lead sheaths, and from the point of view of ease of handling and mechanical considerations generally paper is preferable to metal tapes, which, in order to make them workable, have to be enclosed in a bedding of some softer material. In America C. E. Bennett has developed a system in which oil-filled cables without lead sheaths are installed in an oil-filled steel pipe. The gain in electrical strength of such a system will be much the same as that of the Höchstädter gas compression method just described, and the economic comparison of the two systems will lie more particularly in differences of capital cost and thermal conductivity.

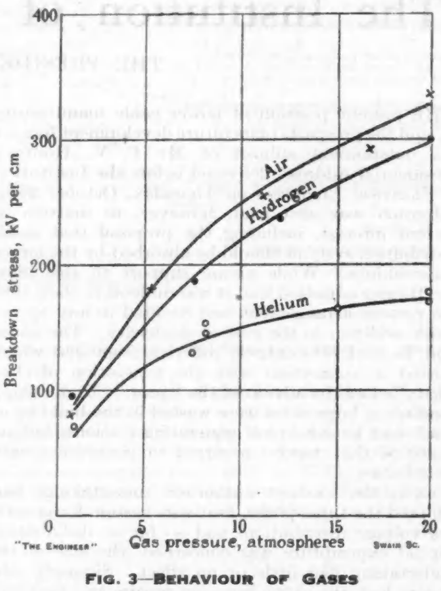

FIG. 3—BEHAVIOUR OF GASES

The gas pressure cable, so called, is one employing in the paper structure gas or gases as both the impregnating and the pressure medium. It presents to investigators an involved problem, as different gases vary in electrical strength, and also in thermal conductivity; and the thickness and density of the paper employed have also a material effect on the electric strength of the cable. Fig. 2 shows the relation between paper thickness and breakdown stress, where compressed nitrogen is used as the filling medium.

The behaviour of different gases is illustrated in Fig. 3, which shows the relation between gas pressure and breakdown stress for air, hydrogen, and helium when used in association with thin Manila paper. Investigation has also been made to determine the effect of a mixture of gases, and an interesting case is that of air and helium—Fig. 4. It will be noted that the poor electric strength of helium is rapidly improved by small additions of air. In this case also thin Manila paper is used with the gases. These results show that it is possible to obtain an increase of from 200 to 300 per cent. in the electrical breakdown strength by raising the compression of the gas used as a filling medium, and by selection of the thickness and density of the paper used a further considerable increase in strength is obtainable.

The discriminating utilisation of these phenomena clearly offers the possibility of producing cables of economical dimensions for the highest voltages. It is in fact doubtful whether breakdown strength will remain the determining factor for the thickness of the dielectric, since at these high voltages the use of a very thin dielectric would give rise to a large capacity current, notwithstanding the fact that the gas pressure cable has a lower specific inductive capacity than the ordinary impregnated cable. Another variable entering into the economic design of a successful cable is the thermal resistance of the dielectric. Helium, for instance, which has a high thermal conductivity, has an indifferent breakdown strength.

C. J. Beaver has suggested that the thermal conductivity of gas pressure cables may be improved by pre-impregnating the paper, and the problem then resolves itself into one of producing a pre-impregnated paper having a good thermal conductivity and also a good power factor. He has also proposed to exhaust the cable instead of filling it with compressed gas, but the vacua required are of a very high order considered from the point of view of commercial operation and possible leakages. It is clear, however, that there are a large number of possible variants; in fact, the difficulty appears to lie in correctly estimating the effect of a number of variables so as to arrive at the best economic design of cable. It seems probable that the resultant cable will require some measure of compensation for capacity current when operating at 132 kV and more, and a convenient method of overcoming the difficulty seems to be that of increasing the magnetising current of step-down transformers.

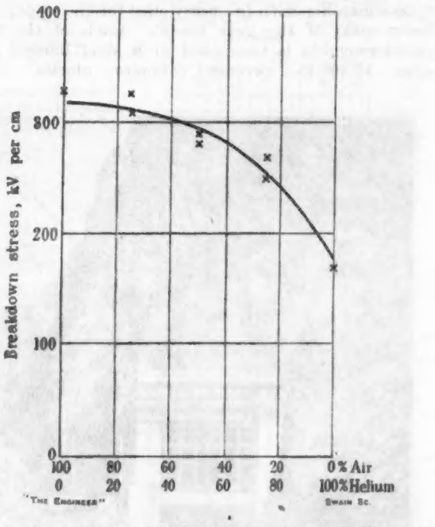

FIG. 4—EFFECT OF ADDITION OF AIR TO HELIUM

PERSONAL AND BUSINESS ANNOUNCEMENTS.

ENGINEER-CAPTAIN H. B. TOSTEVIN, D.S.O., R.N., has been appointed chief engineer of the marine department of the Vacuum Oil Company, in succession to Mr. A. H. Mather, who retired on pension at the end of September, after twenty-eight years' service with the company. He took up his new duties on November 1st.

THE Governors of the Borough Polytechnic have appointed Dr. D. H. Ingall as Principal of the Borough Polytechnic, in succession to Mr. J. W. Bispham, who has been promoted to Assistant Education Officer (Technology) under the London County Council. Dr. Ingall took up his duties on Monday, October 23rd, 1933.

IT was officially announced at a luncheon of the British Electrical Development Association, held at the Savoy Hotel, on Friday, October 27th, that Sir William Ray, M.P. for Richmond, Chairman of the Local Government Economies Committee and leader of the London County Council, has been appointed Chairman of the Association.

MR. ALAN MONCRIEFF, M.C., M.A., A.M. Inst. C.E., M.I. Struct. E., M.I.E. (India), is carrying on the practice of the late firm of J. Mitchell Moncrieff and Partners, consulting engineers, of Westminster and Newcastle-on-Tyne, at 25, Victoria-street, (South Block), Westminster, S.W.1 (telephone, Victoria 9453). The goodwill and all records of the firm, in which he was a partner for some years, have been left to him by his father, the late Colonel J. Mitchell Moncrieff.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY announces that, by virtue of an agreement with the Internationale Benson-Patentverwertungs-A.G., in Zurich, it has obtained patent and manufacturing rights for the United States of the "Benson" boiler. In the manufacture of the boiler the Westinghouse Company will work in collaboration with Messrs. Siemens-Schuckert in Berlin for land boilers, and with Blohm and Voss in Hamburg for ship boilers.

THE INSTITUTION OF CHEMICAL ENGINEERS.—The application forms for the examination for the associate membership for 1934 of the Institution of Chemical Engineers are now ready. These forms are returnable on December 20th, 1933. Application forms and copy of the memorandum on "The Training of a Chemical Engineer" may be obtained from the Hon. Registrar, Institution of Chemical Engineers, Abbey House, Westminster, S.W.1.

---

* *Journal, I.E.E.*, 1909, Vol. 43, p. 113.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Brighter Conditions.

There has been a definite improvement in the tone of the iron and steel markets, probably owing to the placing of a number of contracts for export and the assurance of fresh business coming on the market in the near future. Some of the new contracts have already been referred to in these columns, and, in addition, the shipbuilders in this country anticipate securing contracts for building some of the vessels included in the Brazilian Government's naval programme, which is said to provide for twenty-six warships, including two battle-cruisers, a destroyer flotilla, and submarines. The British railways have also announced programmes which will be a considerable help to the iron and steel makers, just as the mills employed on railway material were beginning to get short of orders. The London and North-Eastern Company has announced that it will enter upon a programme of work involving the expenditure of £2,300,000, which will include the construction of one hundred locomotives, many carriages and wagons, and also the renewal of forty-three bridges and 370 miles of line. On the Continent also some improvement has been noticeable. For some time past there have been reports that the Continental Steel Cartel intended to advance its prices. The situation, however, has been so unfavourable that little attention has been paid to these statements. Over the week-end, however, the rumours grew stronger, and some of the Continental works withdrew their prices. The net result, however, of the Cartel's deliberations was that their c.i.f. quotations for South America were advanced by 2s. to 2s. 6d. gold. It is stated that the c.i.f. prices for India and Japan are to be reviewed, and the quotation for China also has been increased by 2s. gold. As generally happens before a price advance takes place, there was a certain amount of buying by merchants who were able to place contracts before the new quotations became effective. It may be supposed, therefore, that there is at hand another period in which a few fortunate merchant firms will be able to underquote the works official quotations, just as they were able to during the early part of the summer. It is interesting to note that the quotations for the British market are to remain unchanged.

Tube Trade Arrangements.

Interest attaches to the news that the Japanese tube manufacturers have joined the International Tube Association, principally, it is said, as a result of the negotiations which have been conducted by the French Tube Association. The Continental tube makers are closely associated in the International Tube Association with the firms remaining in the British Tube Association and with the American and Canadian manufacturers. There are, however, a number of British tube makers outside the organisation, although for some time negotiations have been proceeding with the object of bringing them into the British Tube Association and into the International Cartel. In these circumstances the agreement with Japan may be regarded as a successful move. It is understood that the Japanese home and colonial markets and the Manchurian market are to be left to the Japanese makers, whilst the other makers in the International Tube Association will deliver certain descriptions of tubes when the market requirements exceed certain prescribed limits. The Japanese makers, however, will adhere to a scale of prices agreed upon by the Tube Association. The agreement extends until 1937, and is expected considerably to reduce the competition for orders which has been going on in the Far Eastern markets. It is interesting to note that the Japanese attempted to invade the British home market, but without much success. The independent British firms and the Swedish makers are not, of course, parties to the new arrangement, but negotiations are taking place with the Swedish makers with a view to bringing them into the International Cartel. If these discussions and the efforts to induce the independent British works to join the British Tube Association are successful the tube industries of the world will be effectively "cartelised."

The Pig Iron Market.

THIS department of the iron and steel trades continues to gather strength. The lull in demand noticed a short time ago, which followed the placing of a number of large contracts for delivery into next year, has passed, and the position is steadily turning in favour of the producers. The stocks which were overshadowing the market are being cleared, and the prospect of prices being advanced owing to the increased cost of coke and ore is causing consumers some anxiety, especially as the ironmasters are not anxious to sell forward at current rates. During the past few weeks the quotation of best Rubio ore has increased from 15s. 6d. to 16s. 6d. per ton, and good Durham blast-furnace coke has advanced from 16s. 6d. to 17s. 6d. d/d furnaces. The market apparently expects higher prices for pig iron; but seems to anticipate an increase in zone prices rather than a general upward movement. The demand for Cleveland iron has expanded, although some relief has been afforded the market by the transference of a furnace from basic to foundry pig iron. It is also expected that another furnace will be started upon foundry iron in the course of a week or two. The situation in this market, however, remains rather tight, and consumers are showing more willingness to buy for next year's delivery than the producers to sell. The Midland ironmasters are not in so strong a position as the Cleveland makers, but the situation in that district has taken a distinct turn for the better. Buying has been confined for the most part to small parcels, but the total tonnage has increased over the past fortnight. The volume of current buying, however, is stated to be sufficient to absorb the production and to call for withdrawals from stock. Similar conditions exist in Lancashire, but the tone of this market has appreciably improved. The light casting foundries producing builders' materials are taking good quantities of iron and a welcome increase in the requirements of the heavy engineering trades is reported. The demand for Scottish irons, both in Scotland and in the English consuming districts, is steady, but does not show any signs of increasing. Some of the Scotch engineering works are taking rather larger deliveries than for some time past. The producers of hematite have at last reached an agreement on prices, which have been advanced 2s. 6d. to home consumers, making the quotation 62s. 6d. for mixed numbers and 63s. for No. 1. The export price is unchanged at 60s. f.o.b. for mixed numbers and 60s. 6d. for No. 1.

Semi-finished Steel.

The chief characteristic of this market is the strong demand for billets and the activity at the British works which are producing this class of material. Business in sheet bars has not been so brisk as in billets, but it seems to be expanding. The busy conditions at the re-rolling works are, of course, responsible for the position in these departments. In the Midlands the quotation for sheet bars, which has been nominally £5 delivered for some time, has advanced to £5 2s. 6d. to £5 5s. For billets also the price is firm at £5 5s. for 500-ton lots and up, ranging to £5 10s. for smaller quantities. Some of the Midland producers are behindhand with deliveries and in some cases have declined to quote for delivery until early next year. There seems to be little to choose between the conditions in the various districts in Great Britain. The works on the North-East Coast, in Scotland, and in Wales are equally busy. The somewhat tight conditions which have developed in this market have encouraged the Continental producers to take a firmer attitude with regard to prices, and a certain amount of business has been transacted at rates which are practically the same as those quoted for British material. In the Midlands Continental 2in. billets have been sold at £5 5s., but it is probable that the Continental works would not let an attractive order pass if it could be obtained by cutting this figure. Apart from occasions when Thomas steel billets are specially required, consumers would prefer to place orders with British producers if the Continental quotation is within a few shillings of the home price, as normally the terms of delivery and payment are more satisfactory. In the present state of the market, however, a number of the re-rollers have thought it wise to take precautions against a possible stringency or fresh advances in price.

Finished Steel Materials.

The general situation has not altered much in the finished steel department, excepting that some encouragement has been given the export side of the market by the Dutch contracts referred to last week and by some orders from China. The latter business is allocated from the Boxer Indemnity Fund, and is for 4000 tons of 60 lb. rails, and constructional steel for bridges. In addition, tenders are to be invited for four 2000-ton boats. It is estimated that the rail and steel contracts will amount in value to £150,000. The home market, however, continues to be the mainstay of the steel works, and the demand is well sustained. The North-East Coast works are busy on constructional steel material, but the rail mills are not so well off for work. The black sheet makers are moderately busy, and although the poor request for shipbuilding steel is still the weak spot, the general position is gradually improving. The Midland steelmakers complain of the light business they are doing in joists and sections, but during the past week the demand has shown signs of increasing. More orders have been booked, and although the constructional engineers refuse to be tempted into placing good-sized contracts, the aggregate tonnage is beginning to grow larger. A satisfactory feature of the situation is the appearance of the colliery companies on the market. The demand from this source has been disappointing this season, but orders amounting to a good tonnage have been placed recently, although the total quantity bought is below the normal for the time of year. The market for small bars is fairly active, and the steel makers producing their own material now ask £7 to £7 5s. for small bars. Re-rollers quote £6 17s. 6d. to £7, but some of them do not let Continental sellers take a good order for the sake of 2s. 6d., and as a result most of the current business is retained in this country, even though Continental merchant bars can be obtained at less than £6 10s., including duty. In South Wales the tin-plate works are operating at over 60 per cent. of capacity, and are keeping their sales ahead of production. Their prices have become firmer at 17s. to 17s. 3d. per standard box.

Scotland, Lancashire, and Yorks.

The recent improvement in business in the Scottish iron and steel markets has been maintained. Most branches of the industry are better employed than for some time. There is, of course, a proportion of unemployed plant, but the general tone of the market is optimistic, and as the season advances business appears to be expanding. The ship repairers are fairly busy, but the call for shipbuilding steel is below normal. There are, however, expectations that fresh shipbuilding contracts will be placed, which would mean more work for the steel mills. Great hopes are entertained that Scottish firms will be successful in tendering for the two new vessels for the Blue Star Line. Some firms report a better inquiry on export account, but only a proportion of this has developed into actual business, and it is difficult to discern any real improvement in the demand from overseas markets. Business in re-rolled material is on the quiet side, and it is in this department the slight improvement in export business is noticeable. Conditions in Lancashire are satisfactory on the whole. Business is particularly good in alloy and special steels, and the demand which has been fair for several weeks past seems to be expanding. There is considerable irregularity in the requirements of the constructional engineers. Some of the local firms are well employed, but others, having completed contracts, are rather badly placed as regards work. An encouraging feature of recent business is that the tonnage of new orders shows a tendency to increase. On the North-West Coast a fairly good flow of business is being experienced, but, as in other districts, the rail mills are beginning to get short of work. Steel makers in the Sheffield district are more optimistic than for a long time. Business in most branches is either steady or expanding. Special steel makers are comfortably off for orders and most of the rolling mills are working full time, whilst the manufacturers of stainless steel are experiencing something in the nature of a small boom.

The Copper Market.

The electrolytic copper market has been largely under the influence of developments in the United States. No one is prepared to prophesy as to the outcome of the American Administration's latest policy of buying gold, and the resulting lack of confidence has been acutely felt in the copper market. Prices have been weaker without any definite reason beyond the uncertainty ruling in all departments of the market and the nervousness displayed by consumers. There has been a certain amount of buying by American and Continental interests as a hedge against currency depreciation, but so complete is the mystification of business men as to the outcome of the American policy that even this has not been on an important scale. The American domestic price has been held at 8½ c., but the export price which had decreased to 8 c., receded slightly to 7.90 c. to 7.95 c., although the movements of the dollar exchange have caused the sterling price to move between £37 and £37 10s. There has been less inclination on the part of American Customs smelters to press sales, and this has helped to check a break in quotations. In Europe consumers are by no means well covered, but at the same time they hesitate to buy important quantities. The German market has been rather active as a result of the German Government's public works programme, but buying from other Continental countries has been restricted to comparatively small quantities. The London standard market has a fairly healthy appearance since the break in prices last week resulted in the liquidation of some rather weak accounts. The sales, however, were easily absorbed, and the undertone of the market is sound, although in common with other metal markets prices have shown a tendency to decline. Apparently there is only a small speculative account open, and operators are displaying a strong inclination to mark time.

The Tin Market.

The event of the week in this market was the announcement by the International Tin Committee that a new agreement regulating output and exports for a further period of three years was signed on October 27th. The new agreement follows the lines which the market has anticipated for some months. The export quotas have been increased from 33⅓ per cent. to 40 per cent. of the standard tonnage, and for 1934 an additional 4 per cent. quota has been agreed to. The agreed standard tonnages are:—Bolivia, 46,490 tons; the Malay States, 71,940 tons; the Dutch East Indies, 36,330 tons; and Nigeria, 10,890 tons; whilst Siam has been given a quota of 9800 tons. The announcement had little effect upon the market, although there was some liquidation which was easily absorbed. Buying by consumers has been on a poor scale. American dealers and consumers have shown practically no interest in the market, whilst Continental buyers have been content to limit their purchases to almost retail quantities. British users, also, have bought sparingly, but the South Wales tin-plate works have continued to take their normal supplies. In the face of these rather poor trading conditions, the market has shown strong powers of resistance to depressing influences. The good statistical position is probably responsible for this, although some disappointment was occasioned by the failure of the International Tin Committee to publish details of its holdings. It was known that the Pool held 21,000 tons of tin for a considerable period, and although it is supposed that a good proportion of this was released during the summer "boom" in this market, dealers would be relieved if the present position was made clear.

Lead and Spelter.

The easier tone in the lead market this week must be attributed to the business uncertainty which has developed since President Roosevelt embarked upon his new monetary policy. There has been no fundamental change in the position, and although stocks are heavy, they are probably not increasing, and in the United States there has been a definite decrease. Buying by consumers has not been active of late, but the lead pipe and sheet makers continue to use good quantities and to provide a steady outlet for the metal. The American price has been increased as a result probably of the depreciation of the dollar, but this has had little influence upon the London market. The Continental consumption of the metal is said to be on a good scale. . . . In the spelter market also prices have reacted without any definite change in the situation to warrant the movement. Business in this metal has been quiet, and the demand from the galvanising trade, which has been light for some time, does not look like improving at the moment, since most of the galvanised sheet makers are short of orders. Probably the demand is just about sufficient to take care of the production. Notwithstanding the weakness in prices, this market seems to be in a healthy condition, and it is probable that any change in sentiment regarding the American position would be quickly reflected in higher prices.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

An Industrial Deadlock.

THE industrial situation is relieved of the menace that overshadowed it as the result of the measures incorporated in the Budget proposals, whereby the Government would have embarked definitely upon the scheme of industrial nationalisation by monopolising the manufacture of war material and firearms, and would have imposed the forty hours' week, without wages reduction, on those makers executing orders under the programme of public works, besides putting further taxes on profits and an exorbitant tax on petrol for motor cars. The Budget proposals were rejected independently of any question of industrial interest, but so violent was the opposition throughout the country to anything being done to interfere with the normal development of trade and industry that the Socialist efforts may be said to have failed beyond hope of recovery. The warnings of exporting industries that the present policy of trade restrictions will inevitably lead to industrial collapse are strengthened by the measures of retaliation adopted by some countries, notably the decree just put into operation by Brazil prohibiting the importation of goods from France except by special licence of the Minister of Finance, whose permission will also be required for a transfer of funds from Brazil to France. These measures are reprisals against restrictions imposed by the French Government on the importation of Brazilian products and against a recent financial decree instituting a system of compensation for debts between the two countries. There are also difficulties with Spain, Portugal, and other countries. The exporting industries insist that the new Government must avoid additional taxation by realising economies in the State administration and carry out immediately negotiations with foreign countries for commercial agreements which will enable them to recover some of their export trade.

The Railway Disaster.

The disaster to the fast express from Cherbourg to Paris on Tuesday morning of last week, when thirty-eight lives were lost and many persons were seriously injured, has raised the question whether the weights and speeds of trains have not reached the limit which the track will bear. The train was a heavy one, hauled by a locomotive of the "Mountain" type, the same as that in service on the Est Railway, where, it is remarked, a similar accident occurred recently, though of a much less serious character and without injury to anyone. At the place where the locomotive was derailed while travelling at 68 miles an hour, a gang had been packing ballast under sleepers in the ordinary course of track maintenance, and it had not been regarded as necessary to put up caution signals against advancing trains. The State Railways affirm that the track cannot be blamed. It is declared by witnesses that the locomotive was rocking dangerously before entering this section, and that it turned over down the shallow embankment at the moment when the brakes were applied. The rails were bent and twisted, and the three first coaches of wood which fell with the locomotive were smashed completely. There is a natural tendency to attribute the accident to a weakening of the permanent way by the operations of the gang, but the alleged behaviour of the locomotive before entering that section of the line complicates an official inquiry which is still proceeding.

Naval Construction.

Whatever economies may have to be effected in State services there is no intention to make cuts in the expenditure on the Navy. While the Estimates for the present year were reduced to aid the Budget as a temporary expedient, the late Minister of Marine declared that the programme of construction would continue normally in 1934, and the fact that the new Premier, Monsieur Sarraut, who succeeded the late Monsieur Georges Leygues, will continue his office as Minister of Marine, indicates the importance he attaches to continuity in the work of building up a strong fleet. It is rather unusual that a public statement should be made of the progress made in naval shipbuilding, and of the performances accomplished by ships recently launched. In the same communication it is affirmed that vessels to leave the stocks shortly will be the 7500-ton cruiser "La Galissonnière" at Brest and two destroyers of 2400 tons, while the cruiser "Jean-de-Vienne" will be launched at Lorient in 1934, and the three cruisers "Marseillaise," "Gloire," and "Georges Leygues," will be laid down at the end of the year. Of the twelve convoys to be built, orders have been given out for ten. Eleven torpedo-boat scouts have been completed, or are nearly ready to be delivered by private builders. These small boats are of various types, some of them in the form of very fast motor boats designed and equipped for launching torpedoes.

Trade with British Dominions.

For the first time the amount of business done with British Dominions is detailed separately in the trade returns issued for the first nine months of the year, instead of being lumped up together amongst "Other foreign countries." So far as Great Britain is concerned, the imports into France totalled 1656 million francs, as against 1821 millions in the similar period of 1932, and the export of French goods and produce to Great Britain amounted to 1191 million francs, as compared with 1486 millions. The imports into France from Canada, totalling 224 million francs, were less than one-half of those for the previous year, and French exports to Canada dropped from 131 million francs to 79 millions. The imports from Australia amounted to 511 million francs, and the French exports to that Dominion were valued at 50 millions. The exports to the Irish Free State were valued at 12,903,000f., and the imports from that country at 7,320,000f. South Africa supplied France with goods to the value of 240 million francs, and took in return French products valued at 33 million francs. The Dominions supply France with raw materials and produce and receive essentially French goods with little in the nature of engineering products.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

TURBINE MACHINERY.

398,432. March 22nd, 1933.—SHAFT PACKINGS, *The British Thomson-Houston Company, Ltd., Crown House, Aldwych, London, W.C.2.*

In this packing the graphite blocks A are held up, each in their separate chambers, to the shaft by the springs B bearing against the metal backing pieces C. The blocks and their backings are cut at an angle, as is shown at D, so that there is a bias for the blocks to bear against the side walls of the chambers and thus ensure an effective seal. A drain is provided at E.—*September 14th*, 1933.

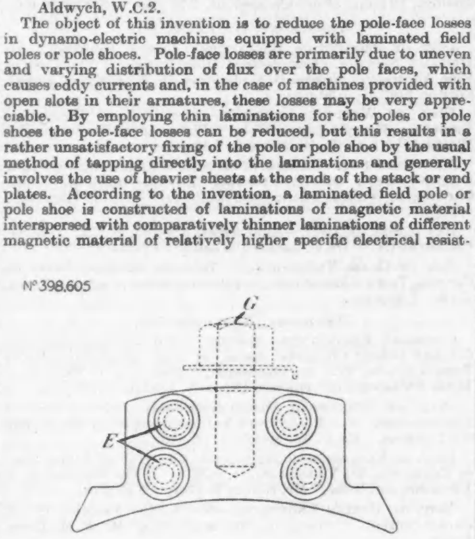
DYNAMOS AND MOTORS.

398,605. May 30th, 1932.—DYNAMO-ELECTRIC MACHINES, Arnold Tustin, of 22, Glentilt-road, Sheffield, York; and Associated Electrical Industries, Ltd., of Crown House, Aldwych, W.C.2.

The object of this invention is to reduce the pole-face losses in dynamo-electric machines equipped with laminated field poles or pole shoes. Pole-face losses are primarily due to uneven and varying distribution of flux over the pole faces, which causes eddy currents and, in the case of machines provided with open slots in their armatures, these losses may be very appreciable. By employing thin laminations for the poles or pole shoes the pole-face losses can be reduced, but this results in a rather unsatisfactory fixing of the pole or pole shoe by the usual method of tapping directly into the laminations and generally involves the use of heavier sheets at the ends of the stack or end plates. According to the invention, a laminated field pole or pole shoe is constructed of laminations of magnetic material interspersed with comparatively thinner laminations of different magnetic material of relatively higher specific electrical resistance than the first-mentioned magnetic material. The field pole illustrated is about 12in. long and 2in. deep and comprises an assembly of laminations of black sheet steel, 0·065in. thick, and laminations of what is commonly known as electric sheet steel, being a silicon steel alloy having a relatively much higher specific electrical resistance than the black sheet steel and 0·014in. thick. In the drawing the ordinary sized laminations are designated A and the special thinner laminations B. The thick and thin laminations are disposed alternately throughout practically the whole length of the field pole and at each end of the field pole there is a packet C of the ordinary laminations, 0·065in. thick, these laminations being spot welded together to serve as rigid end plates for the structure. The assembled laminated structure is longitudinally bored at D to accommodate fixing rivets. As usual, these rivets are in the form of bars, the ends of which are drilled and subsequently flared after insertion in the bores, as shown at E. The laminated structure is also provided with tapped holes F adapted to receive the studs G whereby it is fixed to the yoke of the dynamo-electric machines in which it may be employed.—*September 21st*, 1933.

Nº398,605



TRANSFORMERS AND CONVERTERS.

398,583. April 29th, 1932.—ALTERNATING-CURRENT ELECTRIC DISTRIBUTION SYSTEMS, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2.*

It is often desirable to be able to transform three-phase power with two single-phase transformers. If, for example, one of a bank of three single-phase transformers should fail, it is very advantageous to be able to continue to transform three-phase power in a satisfactory and substantially balanced manner with the remaining two transformers. Heretofore these results have been achieved to a limited extent by the use of two single-phase transformers connected in open delta or V, but the disadvantages of this scheme are well known. According to the invention, the interconnection of the two three-phase circuits is effected by two single-phase transformers, each having two identical primary and two identical secondary windings, one of the primary and one of the secondary windings of each transformer being connected individually in a phase of their respective circuits, while the remaining primary and secondary windings are connected in series in the remaining phase of their respective circuits. Let it be assumed that transformer A, Fig. 1, has failed or that it is desired to secure substantially balanced three-phase transformation by the use of transformers B and C only. Under these circumstances these two transformers are connected as shown in Fig. 2. For purposes of illustration the upper windings are shown to be equivalent star connected, while the lower windings are equivalent delta connected. It will be obvious, however, that these connections could be reversed, if desired, or they could both be equivalent star or equivalent delta connected without departing from the invention in its broad aspects.—*September 21st*, 1933.

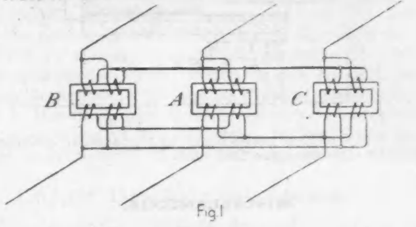

Fig 1

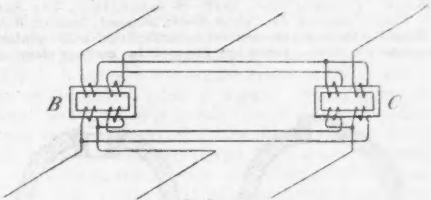

Fig 2

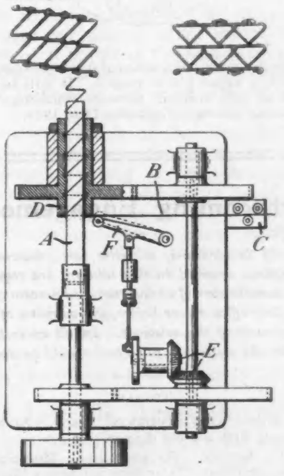
MACHINE TOOLS AND SHOP APPLIANCES.

398,781. May 23rd, 1933.—WIRE NETTING MACHINES, Maschinenfabrik Wafios A.G., and O. C. Schmid, 49, Karlstrasse, Reutlingen, Wurtemburg, Germany.

The essential parts of a machine for producing wire netting of the two types shown in the sketches are shown in the drawing. It comprises a flat rotatable mandrel A on which the wire B is wound after passing through a straightening device C. The mandrel rotates within a snugly fitting sleeve D, formed internally with two helical grooves, one of which is arranged diametrically opposite the other. In these grooves the wire convolutions are engaged at the edges of the mandrel and extended to attain the required shape. For this purpose the mandrel and sleeve are rotated in the same direction, the latter at half the speed of the former. One edge of the mandrel always coincides with one of the entrances to the grooves when it passes the feeding position of the wire. The latter is engaged in the groove and entrained thereby while it places itself across the adjacent flat side of the mandrel. When the opposite edge of the mandrel reaches the feeding position, there is no groove to receive the wire, and the latter will therefore slide along the intact edge of the sleeve during the next half revolution of the mandrel. During this half of the mandrel revolution, therefore, the wire will place itself across the mandrel at right angles to the edges thereof. Thereupon the process is repeated. The mandrel shaft and the sleeve are driven by appropriate gearing. By means of bevel gears E a crank pin reciprocates a plunger which rocks a lever F to press the wire into engagement with the grooves and thus ensure a reliable operation of the apparatus. The mandrel and sleeve may be exchanged to suit the desired wire dimensions and size of meshes.—*September 21st*, 1933.

Nº398,781



METALLURGY.

398,770. April 19th, 1932.—THE DISTILLATION OF READILY VOLATISABLE METALS, Fried. Krupp Grusonwerk Aktiengesellschaft, Magdeburg-Buckau, Germany.

It is complained in this specification that with the usual systems of distilling zinc and similar metals a proportion of the useful metal may be lost on account of its being carried away through condensation on the residue. The kiln recommended by the inventors is of the rotary type and is fed at A by means of a screw conveyor. It is also fired at this end through the supply

B. The ore passes into the annulus C, which feeds the rotating retorts D. The gaseous products, which contain the recoverable metal, go on to the condenser E, which rotates with the retorts D, while the residue passes away by the annular chamber F and outlet G.—*September 21st*, 1933.

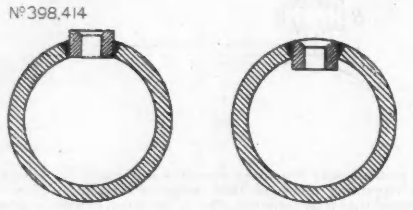
MISCELLANEOUS.

398,414. February 28th, 1933.—SUPERHEATERS, *The Superheater Company, Ltd., Bush House, Aldwych, London, W.C.2.*

Headers for superheaters are manufactured with reinforced portions where the tubes are inserted by making them of a plate bent round to form an almost complete tube, and welding, autogenously, into the gap formed between the edges of the plate a heavy bar, which is drilled for the accommodation of the tubes or any other appurtenances. The illustration needs no comment.—*September 14th*, 1933.

N°398,414



398,416. March 1st, 1933.—CRANK SHAFTS, M. Birkigt, Rue du Capitaine Guynemer, Bois-Colombes (Seine), France.

The balance weights of this crank shaft are connected with the crank webs by means of a series of inter-engaging projections through which a taper pin is passed. It will be appreciated that the pin is only subject, through centrifugal force, to a multiple shearing action.—*September 14th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

TO-DAY.

FARADAY HOUSE OLD STUDENTS' ASSOC.—At Savoy Hotel, W.C.2. Twenty-fifth annual dinner.

INST. OF BRITISH FOUNDRYMEN.—Municipal College, Ormerod-road, Burnley. "Continuous Casting Plant," Mr. F. J. Cook. 7.15 p.m.

INST. OF MARINE ENGINEERS.—Grosvenor House, Park-lane, W.1. Annual conversazione. 7 p.m.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Thomas Hawksley Lecture, "Kinematic Design in Engineering," Professor A. F. C. Pollard. 6 p.m.

INST. OF PRODUCTION ENGINEERS: LONDON SECTION.—83, Pall Mall, S.W.1. "Modern Production Acetylene," Mr. C. Helsby. 7.30 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Safety and Efficiency in Electrical Installation Work," Mr. W. F. C. Cooper. 7.30 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS.—In Literary and Philosophical Society's Lecture Theatre, Newcastle-upon-Tyne. Andrew Laing Lecture, "Recent Metallurgical Developments and their Significance for Shipbuilding and Marine Engineering," Prof. F. C. Lea. 7 p.m.

PHYSICAL SOC.—At Imperial College of Science and Technology, S. Kensington, S.W.7. Editing Committee meeting, 3.30 p.m. Council meeting, 4 p.m. Meeting, 5 p.m.

RAILWAY CLUB.—57, Fetter-lane, E.C.4. "Train Ferries: Their History and Development," Mr. S. R. Yates. 7.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. Discourse, Sir Arthur Hill. 9 p.m.

SATURDAY, NOVEMBER 4TH.

INST. OF BRITISH FOUNDRYMEN.—At Engineers' Club, Manchester. "Continuous Casting Plant," Mr. F. J. Cook. 4 p.m.

INST. OF ELECTRICAL ENGINEERS: NORTH MIDLAND STUDENTS.—Visit to the Hunslet Engine Company, Ltd., Jack-lane, Leeds. Meet at Corn Exchange, Leeds, 2.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

MONDAY, NOVEMBER 6TH.

INST. OF PRODUCTION ENGINEERS: SHEFFIELD SECTION.—Royal Victoria Hotel, Sheffield. "Payment by Results," Mr. S. Carlton Smith. 7.30 p.m.

KEIGHLEY ASSOC. OF ENGINEERS.—Visit to works of Brook Motors, Ltd., Empress Works, Huddersfield. Between 1 p.m. and 4.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. General meeting. 5 p.m.

SOC. OF CHEMICAL INDUSTRY.—At Chemical Soc., Burlington House, W.1. Jubilee Memorial Lecture, "Some Fundamental Scientific Problems of the Food Industry," Dr. L. H. Lampitt. 8 p.m.

SOC. OF ENGINEERS.—In the Rooms of the Geological Soc., Burlington House, W.1. "Nasmyth: Father and Son," Mr. John Wilkie. 6 p.m.

WOLVERHAMPTON AND DISTRICT ENGINEERING SOC.—The Co-operative Hall, Stafford-street, Wolverhampton. The Thomas Lowe Gray Lecture, "Eight Years' Salvage Work at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

TUESDAY, NOVEMBER 7TH.

INST. OF AUTOMOBILE ENGINEERS.—At Royal Soc. of Arts, John-street, Adelphi, W.C.2. "Transmission Principles," Mr L. H. Pomeroy. 7.45 p.m.

INST. OF CIVIL ENGINEERS.—Great George-street, S.W.1. Presentation of Medals awarded by Council. Presidential address, Sir H. P. Maybury, G.B.E. 6 p.m.

INST. OF ELECTRICAL ENGINEERS: LONDON STUDENTS' SECTION.—Visit to the Post Office (London) Railway. 6.40 p.m.

INST. OF ELECTRICAL ENGINEERS: S. MIDLAND STUDENTS' SECTION.—James Watt Memorial Inst., Birmingham. "The Limiting Features of the Alternating Current System of Power Transmission," Mr. H. Rissik. 7 p.m.

INST. OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.—39, Elmbank-crescent, Glasgow, C.2. "Liquid Fuels from Coal for Naval Purposes," Eng.-Capt. S. H. Dunlop, R.N. 7.30 p.m.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—In the Girls' High School, Dudley. "The Interpretation of a Photomicrograph," Mr. J. W. Jones. 7 p.m.

INST. OF PRODUCTION ENGINEERS: EASTERN COUNTIES' SECTION.—In Lecture Hall, Public Library, Ipswich. "Costing and Allocation of Overheads," Mr. K. S. Jewson. 7.30 p.m.

SHEFFIELD METALLURGICAL ASSOC.—Joint meeting with Inst. of British Foundrymen, 198, West-street, Sheffield. Discussion on First Report of the Steel Castings Committee. Introduced by Drs. H. Moore and R. N. Greaves. 7.30 p.m.

TUESDAY AND WEDNESDAY, NOVEMBER 7TH AND 8TH.

INST. OF GAS ENGINEERS.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. Fifth autumn research meeting. Morning sessions, 10 a.m.; afternoon sessions, 2.30 p.m. (See page 406.)

WEDNESDAY, NOVEMBER 8TH.

INST. OF PRODUCTION ENGINEERS: LUTON, BEDFORD, AND DISTRICT SECTION.—Castle-street Hall, Luton. "The Cost of Fine Accuracy," Messrs. B. C. Jenkins, R. Broomhead, and O. Carlton Smith. 7.30 p.m.

INST. OF WELDING ENGINEERS.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Planning for Production by Welding," Mr. G. M. Buchanan. 7.45 p.m.

NEWCOMEN SOC.—At Inst. of Structural Engineers, 10, Upper Belgrave-street, S.W.1. Annual general meeting. "Sir Christopher Wren as a Structural Engineer," Mr. S. B. Hamilton. 5.30 p.m.

ROYAL SOC. OF ARTS.—John-street, Adelphi, W.C.2. "Excavations at Ur." Dr. C. Leonard Woolley. 8 p.m.

SOC. OF GLASS TECHNOLOGY: LONDON SECTION.—Visit to Canning Town Glass Works, Stephenson-street, Canning Town, E.16. 7.30 p.m.

THURSDAY, NOVEMBER 9TH.

CHEMICAL ENGINEERING GROUP.—Joint meeting with the Oil and Colour Chemists' Assoc. at Inst. of Chemistry, 30, Russell-square, W.C.1. Discussion, "Function of Paint as a Metal Preservative." Opener, Dr. L. A. Jordan. 7.30 p.m.

INST. OF ELECTRICAL ENGINEERS.—Savoy-place, Victoria Embankment, W.C.2. "Lower Voltage Sections of the British Grid System," Mr. C. W. Marshall. 6 p.m.

INST. OF ENGINEERING INSPECTION.—In Hall of Junior Inst. of Engineers, 39, Victoria-street, S.W.1. "The Prevention of Vibration and Noise," Mr. Robert B. Gray. 5.45 p.m.

INST. OF MARINE ENGINEERS.—85–88, The Minories, E.C.3. Junior Section. "Pumps for Marine Service," Mr. F. M. Jones. 7 p.m.

INST. OF CIVIL ENGINEERS: BIRMINGHAM AND DISTRICT ASSOC.—At James Watt Memorial Inst., York House, Birmingham. "Rainfall as of Interest to Engineers," Mr. A. A. Barnes. 6 p.m.

INST. OF STRUCTURAL ENGINEERS: YORKSHIRE.—Hotel Metropole, Leeds. "Designing for Welding," Mr. C. Helsby. 7 p.m.

INST. OF METALS: LONDON LOCAL SECTION.—At Royal School of Mines, S. Kensington. "Gold—its Sources and Production," Mr. R. Annan. 8 p.m.

UNIVERSITY OF LONDON.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: iv., Injection: Processes in the Cylinder," Dr. S. J. Davies. 5.30 p.m.

FRIDAY, NOVEMBER 10TH.

INST. OF BRITISH FOUNDRYMEN.—At the Cleveland Scientific and Technical Inst., Corporation-road, Middlesbrough. "Routine Methods of Testing Green Sands," Mr. N. D. Ridsdale. 7.45 p.m.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Informal meeting. Discussion, "Financing Industry," introduced by Mr. Sydney Parkes. 7 p.m.

INST. OF ELECTRICAL ENGINEERS: LONDON STUDENTS' SECTION.—Victoria Embankment, W.C.2. "The Use of Electricity in Rural Areas," Mr. A. L. Cain. 6.15 p.m.

INST. OF METALS: SHEFFIELD LOCAL SECTION.—In Nonferrous Section of Applied Science Department of University, St. George's-square, Sheffield. "Metal Spraying," Mr. W. E. Ballard. 7.30 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. Annual general meeting. 7.30 p.m.

KEIGHLEY ASSOC. OF ENGINEERS.—Queen's Hotel, Keighley. "Petroleum: From Well to Consumer," Mr. F. L. Slee. 7.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. Discourse, Mr. N. V. Sidgwick. 9 p.m.

SATURDAY, NOVEMBER 11TH.

INST. OF BRITISH FOUNDRYMEN.—Technical College, Monks-road, Lincoln. "Use of Refractory Materials in the Foundry," Dr. J. G. A. Skerl. 7 p.m.

INST. OF MARINE ENGINEERS: JUNIOR SECTION.—85–88, The Minories, E.C.3. Social and dance. 7.30 p.m.–11.15 p.m.

INST. OF MECH. ENGINEERS: GRADUATES.—Visit to Brookman's Park Wireless Station. Particulars from Hon. Sec., Graduates' Section, 28, Essex street, Strand, W.C.2.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

MONDAY, NOVEMBER 13TH, TO SATURDAY, NOVEMBER 18TH.

PUBLIC WORKS CONGRESS AND EXHIBITION.—Agricultural Hall, Islington, N.1. Daily. (For programme see page 365).

MONDAY, NOVEMBER 13TH.

INST. OF METALS: SCOTTISH LOCAL SECTION.—At Inst. of Engineers and Shipbuilders in Scotland, 39, Elmbank-crescent, Glasgow. Discussion on papers presented at the autumn meeting of the parent Institute. 7.30 p.m.

STEPHENSON LOCOMOTIVE SOC. (SCOTLAND).—In L.M.S.R. Societies' Room, Royal Technical College, Glasgow. "The Economic Life of the Locomotive," Mr. John Scott. 7.45 p.m.

TUESDAY, NOVEMBER 14TH.

CHEMICAL ENGINEERING GROUP.—At the Public Works, Roads, and Transport Exhibition, Royal Agricultural Hall, Islington, N.1. Conference, "The Mechanical Testing of Bituminous Road Materials." Sessions 11 a.m. and 3 p.m.

INST. OF AUTOMOBILE ENGINEERS.—At King's Head Hotel, Coventry. "Transmission Principles," Mr. L. H. Pomeroy. 7.30 p.m.

INST. OF MARINE ENGINEERS.—85–88, The Minories, E.C.3. "Welding for Pressure Vessels," Mr. R. Sulzer. 6 p.m.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—In James Watt Memorial Inst., Birmingham. "Deoxidisers and Fluxes," Mr. G. L. Bailey. 7 p.m.

INST. OF METALS: N.E. COAST LOCAL SECTION.—Joint meeting with the Newcastle-upon-Tyne Branch of Soc. of Chemical Industry, in Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-upon-Tyne. "Metal Spraying," Mr. W. E. Ballard. 7.30 p.m.

INST. OF METALS: SWANSEA LOCAL SECTION.—At Y.M.C.A., Swansea. "Ageing and Age Hardening," Dr. Cecil H. Desch, F.R.S. 6.15 p.m.

SHEFFIELD METALLURGICAL ASSOC.—198, West-street, Sheffield. "Intergranular Corrosion of 18/8 Austenitic Steels," Mr. E. C. Rollason. 7.30 p.m.

WEDNESDAY, NOVEMBER 15TH.

INST. OF ELECTRICAL ENGINEERS: METER AND INSTRUMENT SECTION.—Pagani's Restaurant, 42, Gt. Portland-street, W.1. Annual dinner. 6.45 p.m. for 7 p.m.

MANCHESTER METALLURGICAL SOC.—At College of Technology, Manchester. "Hardness of Metals," Dr. H. O'Neill. 7 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS: GRADUATES.—Bolbec Hall, Newcastle-upon-Tyne. "Leaves from an Engineer's Log," Eng.-Comr. C. J. Hawkes, R.N. 7.15 p.m.

THURSDAY, NOVEMBER 16TH.

BRITISH WATERWORKS ASSOC.—Agricultural Hall, Islington, N.1. To receive and discuss the following papers:—"Pooling of Supplies by Interconnection of Water Undertakings and their Trunk Mains through Rural Areas," Mr. Alan E. L. Chorlton; "Water Pollution Research," Dr. A. Parker. 11 a.m. Afternoon session: "The Financial Management of Municipal Trading Departments," Mr. Sydney Larkin; "Water Supply and Fire Protection," Mr. John Smith; "Fire Prevention and Fire Extinguishing Apparatus," Major F. W. Jackson; "The Legal Aspect of Water Supply for Fire Protection Purposes," Mr. John Hall. 2.45 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS: TEES-SIDE BRANCH.—Cleveland Scientific and Technical Inst., Corporation-road, Middlesbrough. "Rudder Streamlining Technique," Dr. E. V. Telfer. 7.30 p.m.

UNIVERSITY OF LONDON.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: v., Ignition and Combustion Properties of Fuels," Dr. S. J. Davies. 5.30 p.m.

FRIDAY, NOVEMBER 17TH.

FINSBURY TECHNICAL COLLEGE OLD STUDENTS' ASSOC.—At Inst. of Chemistry. Sixteenth Streatfield Memorial Lecture, "Beer," Mr. H. F. E. Hulton. 8 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Recording Sound for Motion Pictures," Mr. W. Harris. 7.30 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS.—Bolbec Hall, Newcastle-upon-Tyne. "Economics in Tramp Ship Design," Mr. W. Leslie Runciman. 6 p.m.

OVERHEAD LINES ASSOCIATION.—At Georgian Restaurant, Harrods, Ltd. Annual conversazione.

MONDAY, NOVEMBER 20TH.

INST. OF ELECTRICAL ENGINEERS: WESTERN CENTRE.—At Cheltenham. Discussion on "Gale and Storm Damage." Opener, Mr. W. D. Tuck.

TUESDAY, NOVEMBER 21ST.

INST. OF AUTOMOBILE ENGINEERS.—At Victoria Hotel, Wolverhampton. "The Correlation of Metallurgical and Economic Problems in the Selection of Automobile Engineering Materials," Mr. L. B. Hunt. 7.30 p.m.

SHEFFIELD METALLURGICAL ASSOC.—198, West-street, Sheffield. Discussion, "Rolling Faults in Steel," Mr. G. M. Brown. 7.30 p.m.

WEDNESDAY, NOVEMBER 22ND.

INST. OF AUTOMOBILE ENGINEERS.—At Engineers' Club, Albert-square, Manchester. "Transmission Principles," Mr. L. H. Pomeroy. 7 p.m.

ROYAL SOC. OF ARTS.—John-street, Adelphi, W.C.2. "Radiographic Use of Radium," Dr. V. E. Pullin. 8 p.m.

THURSDAY, NOVEMBER 23RD.

ANNUAL CHEMICAL DINNER.—Wharncliffe Rooms, Hotel Great Central, Marylebone, N.W.1. Dinner, 7.30; dancing, 9.15 p.m.

SHEFFIELD METALLURGICAL ASSOC.—198, West-street, Sheffield. "Applications of X-rays to Metallurgical Investigations," Mr. J. W. Rodgers. 7.30 p.m.

UNIVERSITY OF LONDON.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: vi., Designs of Combustion Chambers—Actual Performance—Trends of Development," Dr. S. J. Davies. 5.30 p.m.

TUESDAY, NOVEMBER 28TH.

INST. OF ELECTRICAL ENGINEERS: SCOTTISH CENTRE.—Grosvenor Restaurant, Gordon-street, Glasgow, C.2. Annual dinner and ladies' evening. 6.30 p.m. for 7 p.m.

THURSDAY, NOVEMBER 30TH.

INST. OF CIVIL ENGINEERS: YORKSHIRE ASSOC.—Hotel Metropole, Leeds. Short paper by students for discussion. "Tramway Reconstruction," Mr. C. R. Warman: "An Economic Aspect of Reinforced Concrete," Mr. E. A. Dyer. 7.30 p.m.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—In James Watt Memorial Inst., Birmingham. "Symposium on Defects in Cold Working," arranged by Mr. A. L. Molineaux. 7 p.m.

A Seven-Day Journal

The "Back to Coal" Movement.

In a Journal note of August 26th, 1932, we referred to the strengthening of the "Back to Coal" movement by the co-operation of a number of coal-utilisation experts and Welsh Members of Parliament. Following up its efforts to secure the substitution of coal for oil for use on British naval vessels, the "Back to Coal" movement has again petitioned the Board of Admiralty to receive a deputation to enable the members to place their case before the Board. The communication is signed by the Lord Mayor of Cardiff, as President of the movement, and by the three hon. secretaries. The letter recalls that in July, 1931, a deputation interviewed the Lords of the Admiralty, but the late Board of Admiralty then found itself unable to accede to the deputation's request by reason of existing conditions in regard to construction and equipment, which were dictated for the most part by the necessity to ensure the greatest possible advantages while maintaining international agreements. The movement has been advised that these conditions may not necessarily continue, and that, in fact, considerable changes have already taken place. For this reason there is a strong feeling throughout South Wales that events subsequent to July, 1931, have considerably strengthened the case which was laid before the previous Board. The movement therefore desires to know whether the present Board of Admiralty will receive a second deputation. If so, it is proposed that, with the consent of the Board of Admiralty, such a deputation should be supported by coal utilisation experts.

Business Forecast.

The F.B.I. Business Forecast for the fourth quarter of the year reflects the general upward movement of industry. It is that "despite the many unfavourable factors still operating in the international field, and in particular the recent setback in the U.S.A., it is possible to view the future with optimism. The world may be said to have planted its feet so firmly on the road to recovery that it will take something more drastic that such transitory events as the instability of the French franc or the American dollar to divert it from its course. Even should there be some modification of the French gold standard, or a further appreciable flight from the dollar, there is no reason why we should not be able to retain control of our domestic situation. The same is true of many other countries." The quarterly report of the Federation notes that a large part of the recovery in the third quarter of the year was attributable to home trade, but that the recovery in our foreign trade also gathered some momentum during the quarter. Domestic exports increased from a monthly average of £21·9 millions to £23·8 millions, while retained imports rose from £11·5 millions to £13·4 millions.

G.W.R. Development Schemes.

At the end of last week the Great Western Railway Company announced a two million building programme for the coming year. The locomotive programme includes the construction of ninety engines, ten of which will be of the four-cylinder 4-6-0 "Castle" class and ten of the two-cylinder 4-6-0 "Hall" class for use on the principal express passenger trains. Another thirty engines will be for local and suburban service, and there will also be twenty-five engines of the 0-6-0 tank class and fifteen auto engines. The rolling stock programme includes 200 passenger vehicles and, on the freight side, 850 12-ton vacuum fitted vans and 1080 12-ton non-vacuum fitted vans exceeding a total of a million pounds for rolling stock for express freight services. During 1934 over 400 miles of line are to be relaid, which will involve the use of 30,000 tons of rails and 600,000 sleepers, a proportion of which will be made of steel, while 185,000 tons of ballast will be required. Over a quarter of a million pounds is to be spent on the maintenance and reconditioning of stations, buildings, and fencing.

Coal Dust Explosions.

The recent paper No. 79, recording the experiments carried out by Mr. T. N. Mason and Mr. R. V. Wheeler for the Safety in Mines Research Board, published by the Stationery Office, marks a further advance in knowledge of the means of preventing coal dust explosions. Hitherto it has been usually assumed that the nature of the incombustible dust used for the treatment of mine dusts is unimportant. This view is supported by the Home Office Explosions in Mines Committee, which in 1914 stated that the fineness of incombustible dust rather than its chemical composition afforded a measure of its probable effectiveness in preventing the ignition of the coal dust with which it was mixed. The authors above named have recently made experiments with seven different kinds of incombustible dusts, and their results are given in the paper. Compared with the shale dusts in common use, limestone and gypsum were found to be more markedly effective in rendering coal dust incapable of propagating flame. The authors, however, give a warning in which they remind possible users that when assessing the value of an incombustible dust for the treatment of coal dust the ease with which it can be dispersed as a cloud, more particularly after it has been exposed to the atmosphere of the mine for some time, must always be considered. In this respect it is pointed out that gypsum is more likely to cake than is either limestone or shale dust.

Two Noteworthy Launches.

On Thursday afternoon, November 2nd, there was launched from the Pallion Shipyard of Short Brothers, Ltd., Sunderland, the "Arcwear," the first of three Arcform steamers which are being constructed to the order of Sir Joseph W. Isherwood and Co., Ltd. The ship is of the single-deck type with a length of 360ft., an extreme breadth of 57½ft., and a moulded depth of 26ft. 9in. She will have a deadweight carrying capacity of about 7000 tons on a summer loadline of 22ft. 7in. Steam propelling machinery will be installed, and the boilers will be designed to burn coal. The results of tests show that, at a speed of 9 knots, about 11½ tons of coal will be used, at 10 knots about 16 tons, and at 11 knots about 21 tons per day. The naming ceremony was performed by Lady Isherwood. The "Arcwear" is being constructed to Lloyds highest class, and is built on the Isherwood combined system of transverse side framing with longitudinal framing in the double bottoms and erections. The second important launch during the week was the "British Coast," the largest British coastal motor liner yet built, which was launched from the Leith yard of Henry Robb, Ltd., on Saturday, November 4th, for the service of Coast Lines, Ltd. The keel plate of a sister ship, to be named the "Atlantic Coast," was immediately laid. The new coastal liner has a deadweight carrying capacity of 1400 tons on a draught of 13ft. 11in., and she is 230ft. in length with a moulded breadth of 35ft. and a depth to shelter deck of 21ft. 6in. Her twin-screw Polar type oil engines are being supplied by British Auxiliaries, Ltd., of Glasgow, and have a designed output of 1250 B.H.P. total, corresponding to a speed of about 12 knots. The official trials will be made in December.

Chelsea Bridge.

At a meeting of the London County Council, held on Tuesday, November 7th, a report of the Improvements Committee, which recommends the reconstruction and widening of Chelsea Bridge to take four lines of wheeled traffic, was adopted. As recorded in a Journal note of June 26th, 1931, the original plan was for a new suspension bridge carrying six lines of wheeled traffic, which was to be built at an approximate cost of £659,250, to the designs of the Council's architect and Sir Frederick Palmer, P.P. Inst. C.E. The scheme now approved provides for the reconstruction and widening of the existing structure at a cost of about £480,000. The Committee proposes to consult the Royal Fine Art Commission on the design to be adopted. The new bridge will have a 40ft. carriageway and two 12ft. footpaths, and the Ministry of Transport will make a grant at a rate of 60 per cent. towards the approved expenditure. The sum of money above mentioned includes the cost of a temporary bridge while the reconstruction work is proceeding. The work will be carried out to the designs and under the supervision of Messrs. Rendel, Palmer and Tritton, of Westminster.

Improved Employment Figures.

Early in the week the Ministry of Labour announced that on October 23rd there were 44,000 more persons in employment than there were a month ago, and 537,000 more than a year ago. The estimated number of insured persons in employment last month was 9,925,000. As in the case of last month, for which the employment particulars up to that date were given in our Journal note of October 13th, the largest reduction was in coal-mining, over 13,000 more miners being employed. Reduction in unemployment continued also in the metal industries other than the manufacture of iron and steel. Thus the following decreases were noted :—General engineering, 6600; motor vehicles, &c., 5000; and metal goods manufacture, nearly 7000. In the iron and steel industry, on the other hand, unemployment increased by nearly 2800 persons, and there were also small increases in occupations affected by seasonal influences, including the following :—Building, 1000; public works contracting, 1000; road transport, 1450; shipping, 5000; and distributive trades, 4000. In all trades, however, there were remarkable decreases in unemployment compared with the returns for October last year.

Technical Education and the Future.

In an address given on Friday, November 3rd, in connection with the prize distribution at the Wolverhampton and Staffordshire Technical College, Professor E. W. Marchant, of the University of Liverpool, paid a tribute to the work the College was doing in the interests of the economic development of higher technical education. An interesting part of his address was devoted to the future development of such education. Professor Marchant suggested that owing to the mechanisation of industry the number of people employed in manufacturing work during the next decade would almost certainly diminish. It seemed to him very uncertain as to whether the standard of living, or, rather, he said, the standard of need for additional amenities, would have then advanced sufficiently to enable all those who were so displaced to enter the new factories designed to supply the new needs. For the present, at any rate, there was no doubt of a surplus of labour. Suggestions had been made for the raising of the school-leaving age in order to prevent so many young people leaving school from becoming unemployed. Could we not, he said, take a similar action in respect to evening class instruction ? If evening class instruction were to be replaced by instruction in the daytime, it would mean a great improvement in the training of the student.

Copper Development Association.

The Copper Development Association, which now occupies offices at Thames House, Millbank, S.W.1, has been recently formed in order to promote the use of copper and copper-containing materials. For the present it is proposed to concentrate on the development of extended uses of copper rather than on research work, since it is felt that such development has not kept pace with the very rapid progress which research has made during the past few years. Contact has been established with the Copper and Brass Research Association in America, and with the Copper Institute of Germany, with a view to the interchange of information. The Association has unrivalled opportunities for the collection and dissemination of information, and the hope is expressed that engineers will avail themselves of the facilities it offers. The honorary Presidents of the Association are Sir Auckland Geddes, Mr. A. Chester Beatty, and Sir Harry D. McGowan; and it is directed by a Council, of which Mr. D. Owen Evans is Chairman and Lieut.-Colonel Preston Vice-chairman. The conduct of detailed business is vested in a Management Committee, of which Mr. A. D. Storke is the Chairman, and on which most of the important copper interests, including trade associations, are represented. The Vice-chairman of the Management Committee is Mr. S. S. Taylor, and other members are Mr. W. R. Barclay, Mr. Thomas Bolton, Mr. J. C. Budd, Mr. G. W. Mullins, Mr. E. Pam, Mr. C. H. Schneider, and Mr. A. J. G. Smout. Mr. D. P. C. Neave is the general manager of the Association, and Mr. G. W. Preston, A.M.I.E.E., has been appointed its electrical engineer.

The Dowlais Steel Works Project.

Plans for the erection of the new Dowlais works at Cardiff by the British (Guest, Keen and Baldwins) Iron and Steel Company, Ltd., are being pushed forward. The site is now being cleared, and, more important still, negotiations with the local authorities are making satisfactory progress. The scheme provides for the manufacture of 300,000 tons of billets and sheet bars per annum with provision for an increased output if required, the cost being estimated at £2,000,000. A further step in the negotiations was made on November 7th, when a deputation from the Cardiff County Council, headed by the Lord Mayor, met the directors of the company at their London office. It is understood that the discussion concerned details relating to local administration, such as rates, electricity, and water supply, which, naturally, are of considerable importance to the company. Whilst progress is being made in this direction the company will be faced later on with the problem referred to by Sir John Beale, the chairman, in his letter to the Cardiff Corporation, in which he pointed out that the protective duties on which the scheme is based have barely a year to run, whilst the capital expenditure could not be justified by a plan based on a shorter outlook than "twenty years or so."

The Late Mr. Adam Hunter.

Bridge engineers will learn with great regret of the death of Mr. Adam Hunter, late chief engineer of Sir William Arrol and Co., Ltd., which took place at his home in Rutherglen on Thursday, November 2nd. Mr. Hunter joined the firm as a young man, and some of his early work was connected with the building of the Forth Bridge. He was a Telford Medallist, and showed marked talent for design, so that he was sent to London as chief designer. About twenty years ago he returned to Glasgow as chief engineer and director of his firm, and only retired last year. He was personally responsible for the design and building of many notable bridges, both in this country and abroad. We well recall the interest he showed in the putting into position of the large span of the temporary Waterloo Bridge. Adam Hunter was an honoured member of the Institution of Civil Engineers, and contributed to its "Proceedings." He was also President of the Students' Section in Glasgow, and a President of the Glasgow University Engineering Society. His outstanding abilities as a bridge builder were widely recognised, and younger engineers owed much to his kindly advice and help, which was often sought and was never refused. His death will be widely regretted by his late colleagues, and the many engineers who from time to time consulted him in connection with bridge construction schemes.

Recent Hydro-Electric Power Plants in Sweden.

No. I.

AMONG the many hydro-electric power stations in Sweden which were visited by the members of the International Congress on Large Dams in July last are three of special interest, which we propose to describe in a short series of illustrated articles, of which this is the first. These installations are at Krangede, and at Sillre in Lower Norrland, and at Vargön near the outlet of the great lake Vänern; novel features of design and construction are exhibited in each of them. The works at Krangede are under construction and will not be in operation until 1935 or 1936; at Sillre some work was still in progress on the dam when it was visited by the members of the Congress in July, although the plant had been brought into use in April last. The first section of the Vargön works, in some respects the most interesting of the three, is now nearing completion and is expected to be in operation early in 1934. We shall also make brief reference to the older power stations, which are or will be linked with these new installations and operated in conjunction with them.

FIG. 5—STATE POWER STATIONS AND MAIN TRANSMISSION LINES IN SWEDEN

I.—THE HYDRO-ELECTRIC POWER PLANTS OF THE GOTA RIVER.

The Swedish Government Department responsible for the administration of State-owned electric power plants is the Royal Board of Waterfalls (Kungl. Vattenfallsstyrelsen), a body which also controls all waterfalls, developed or undeveloped, and canals belonging to the State. The Board supplies electric energy to three separate areas, viz., the Central Block, the Norrfors, and the Porjus areas—Fig. 5. The Central Block area comprises parts of Central and Southern Sweden, and the Norrfors and Porjus areas are in Upper Norrland, a large part of the latter area being within the Arctic Circle.

The bulk of the energy distributed by the State in the Central Block area is derived from hydro-electric installations on the Götaälv (Göta River), which, from the point of view of flow, is the largest river in Sweden. The first of these stations, that at Trollhättan, was brought into operation in 1910 and is the largest power plant in Sweden. The river is the outlet of Lake Vänern to the sea at Göteborg and has a total fall of about 44·3 m. in 90 kiloms. The flow of water is very even in character, thanks to the effect of the lake, whose water area is 5550 square kilometres, and is the largest in Sweden and the third largest in Europe. The new power station at Vargön, to be brought into use early in 1934, will make use of the difference in level between Lake Vänern and Trollhättan, which, when the regulation of the lake is in operation, will be, on the average, about 4·3 m. The falls at Trollhättan provide the head of 32 m. utilised at that power station and the plant at Lilla Edet, between Trollhättan and the sea, utilises the fall between the lowest level at Trollhättan and sea level, 6·5 m. Thus, on the completion of the Vargön works, the whole of the available head between Lake Vänern and the sea will be utilised.

Particulars of the Götaälv installations are given in the table above.

Plant.	In operation since.	Drainage area, kiloms.².	Kiloms. from Lake Vänern.	Flow, m.³/sec.			Utilised head. m.	Number and type of turbines.	Total installed machine capacity, kW.	Available output, kW.	Average energy available, millions kWh.	Energy produced in 1932 (net), millions kWh.	Maximum load, 1932, kW.
				Min.	Mean.	Max.							
Vargön (under construction)	(1934)	46,750	1·5	295	500	830	Min. 3·0. Max. after regulation about 5·0	2 Kaplan	About 20,000	About 20,000	115	—	
Trollhättan	1910	46,920	11	295	500	830	32·0	13 Francis	140,000	127,000	1050	812	
Lilla Edet	1926	47,470	31	300	505	835	6·5	2 vertical (fixed blades), 1 Kaplan	26,000	26,000	190	161	
Totals: Götaälv Stations ..	—	—	—	—	—	—	43·0	—	186,000	173,000	1355	973	
Totals for Central Block, including two other hydraulic stations and Västeras steam station ..							—	—	400,000	350,000	—	1288	225,900

The Trollhättan station cannot at present produce more than 127,000 kW owing to the restricted dimensions of the intake canal. When this is enlarged the full capacity of the existing plant, 140,000 kW, can be developed.

The State hydro-electric plants now in operation in the Central Block area—Fig. 6—totalling about 250,000 kW installed capacity, represent about 20 per cent. of Sweden's total developed water power. The plants are interconnected with one another and with the Västeras auxiliary steam power plant of 110,000 kW. The latter forms an energy reserve at periods of low water and a general reserve in case of emergency, and is otherwise run either as a peak load station or as a synchronous motor station to regulate the tension of the transmission system. The steam plant of the city of Göteborg (21,000 kW) also acts as a standby plant to the Central Block system.

FIG. 8—GENERAL PLAN OF REGULATING BARRAGE AND VARGON POWER STATION

The future network of State transmission lines, intended to connect Southern and Central Sweden with Southern Norrland, will operate under a pressure of 220,000 volts, and therefore the towers of the western trunk line Trollhättan-Västeras were designed to admit of this voltage, but at present the line is operated at 132,000 volts.

In 1929 the power demand approached the upper limit of the capacity of the Central Block plants. It was then decided to develop the water power at Vargön, near the outlet of Lake Vänern, and at Malfors on the Motala Ström. At each of the proposed stations it was possible to install turbines of over 20,000 kW capacity. The construction work at Vargön is now nearly completed, but the Malfors plant is not expected to be in use before 1935 or 1936.

The Regulation of Lake Vänern.—Regulation of the water supply from Lake Vänern became possible on the completion of the barrage at Vargön. Weekly regulation was brought into operation this year, but it is probable that yearly regulation of the lake will not be possible for several years—probably five years—as the scheme of regulation prepared by the Royal Board of Waterfalls is subject to decisions of the courts respecting the rights of landowners and others which will be affected. The possibilities of regulation of Lake Vänern are exceptionally good because of its great area. The height of regulation proposed by the Board is 1·7 m.; this storage capacity is equivalent to not less than 850 million kWh—that is, about 60 per cent. of the total quantity of energy which can be produced in a year of normal flow by making full use of the Götaälv. A change in water level of 1 cm. corresponds to about 5 million kWh.

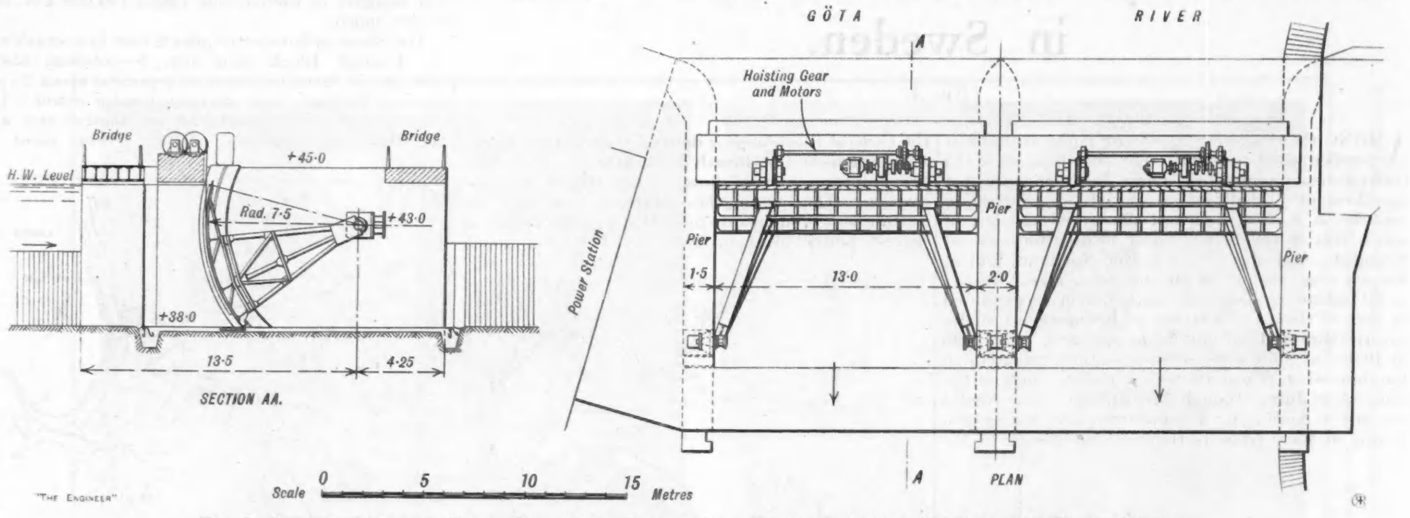

FIG. 9—SECTOR GATES IN MAIN OUTLET OF REGULATING BARRAGE—CROSS-SECTION AND PLAN—VARGON

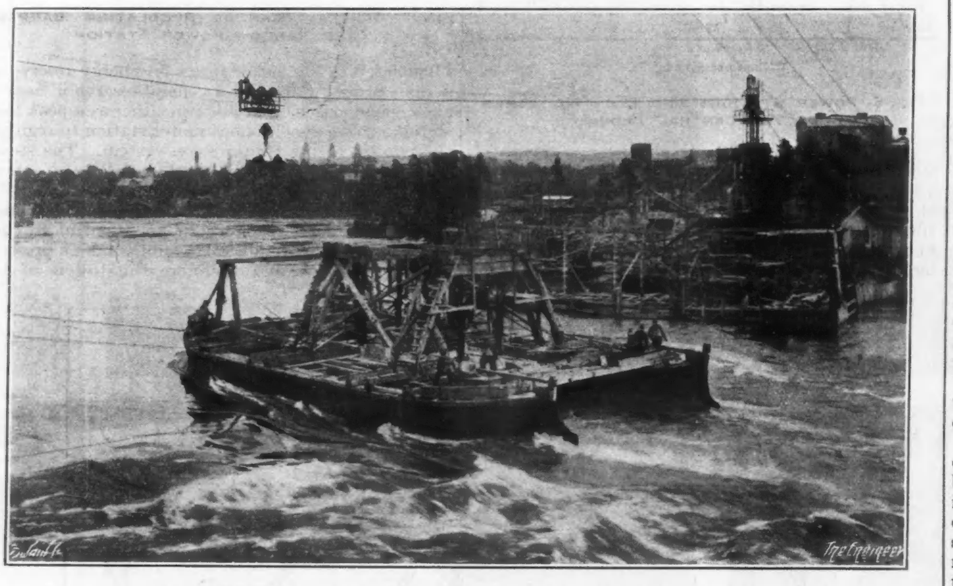

FIG. 10—SINKING A CAISSON IN THE VARGON RAPIDS—MAY, 1930

There will be a surplus of reservoir capacity available for equalisation over several years; thus advantage can be taken during low water years of savings effected during times of high water. Calculations have shown that, thanks to the great Vänern reservoir, it will be possible, by means of the Götaälv power stations, to furnish so much surplus energy to the State power systems in Central Sweden, including those to be erected in the Indalsälven in Lower Norrland, that only an insignificant supplement will be required from the steam plant during times of low water for the whole of the Board's network of power stations.

To enable the Götaälv plants to perform this duty it is proposed to enlarge them to deal with a flow up to 900 m.^{3} per second. In the future these installations will work as base load plants during the six winter months when the other State plants have at disposal only a reduced flow of water. During the six summer months their normal function will be to work as peak load plants. Tapping of Lake Vänern will only be resorted to in those years when the power plants of other systems have a low flow of water. As an example of the importance of the Vänern reservoir it may be stated that by tapping 0·25 m. of the reservoir capacity it is possible to obtain the power to produce as much electrical energy as would require about 100,000 tons of coal to produce by steam power.

The weekly regulation of Lake Vänern can be carried out without affecting the shores, provided it is possible to measure and regulate very accurately the discharge at any time. Before and during the construction of the barrage at Vargön (1929–31) an elaborate series of model experiments was carried out in the Hydraulic Structures Laboratory of the Royal Technical University at Stockholm in order to obtain accurate data upon which the discharge could be calculated under varying conditions. Measurements made from October to December, 1932, at the barrage of the actual flow were found to give results which correspond very closely with those obtained from the model experiments.*

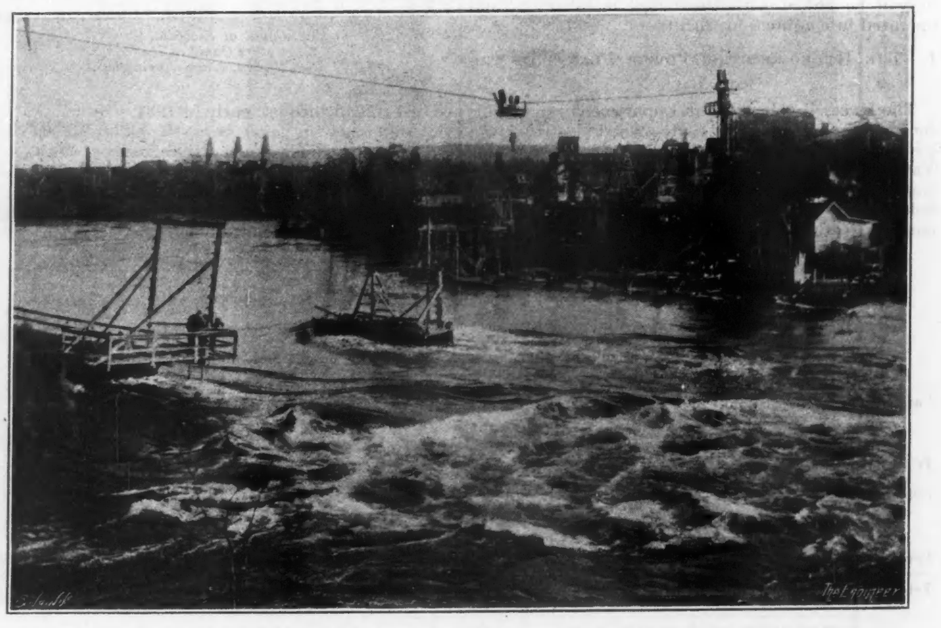

FIG. 11—THE MIDDLE CAISSON FOR THE POWER STATION FOUNDATIONS IN POSITION IN THE RAPIDS—JANUARY, 1930

After the complete regulation of Lake Vänern, the net head utilised at the Vargön power plant will have an average value of 4·3 m. and a maximum of about 5·0 m. Until then the average figure will be about 3·3 m. The available energy at this head will be about 85 million kWh. With a head of 4·3 m. 115 million kWh will be available.

THE VARGON HYDRO-ELECTRIC POWER STATION.

The plant now being installed at Vargön is remarkable in several respects and is of much technical interest. The Kaplan turbines, having runners of 8 m. diameter, the largest yet constructed, are designed for an exceptionally small head—3·0 m. to 5·0 m.—and are placed above the upstream water level; consequently the water supply to the turbines will rely on syphonic action. There is no powerhouse superstructure, the generators being housed in removable steel covers, a novelty in Swedish practice.

The regulating barrage and power station are constructed in the main channel of the Götaälv, which, at the site of the works, 1·5 kiloms. below the outlet of Lake Vänern, is about 200 m. wide, but was obstructed by several small, rocky islets—see plan, Fig. 7. Before the barrage was built—1929–31—the river formed swift rapids over the rock bed between Vargön Island and Onafors. Water traffic between the lake and the Göta River passes by way of a locked canal about 2 kiloms. west of Vargön Island.

Regulating Barrage.—The whole of the barrage, containing four outlet channels closed by gates, was built before the construction of the power station itself was begun—Fig. 8. The river flow was concentrated in the deep channel, where now the power station is being built, while the several parts of the regulating barrage were constructed in the dry within timber cofferdams founded on the rock bed of the relatively shallow side channels. Conversely, while the building of the power station has been in progress the river has discharged through the openings in the regulating barrage. Three of these openings in the barrage are provided with sector gates and the fourth is closed by a sliding gate. All these have been designed with a view to accurate measurement of the water discharge. The sector gate, 13 m. wide, at the Svarta Halan on the east side is designed for discharge

---

[*] "Researches Concerning the Discharge Conditions at the Vargön Regulation Weir," by W. Fellenius and E. Lindquist. R. Tech. Univ., Stockholm; Publication No. 7, 1933.

under the gate as well as for use as an overflow weir. The two sector gates in the main outlet adjoining the power station on its east side are each 13 m. wide and are designed for discharge under the gate—Fig. 9. The Lilholm outlet has a 10 m. wide roller sluice gate.

In order to improve the flow of the river in that part which constitutes the head-race, and to minimise hydraulic losses, an artificial channel has been excavated in the rock at Sjöboda—Fig. 7. The river has also been widened and deepened along another section at Nyebro. Before the full regulation of Lake Vänern is in operation another artificial channel will be excavated in the rock at the Huvudnäs rapids—Fig. 7.

The Power Station Cofferdam.—The construction of a cofferdam, forming a rectangle of about 50 m. each way on a hard rock bottom in a river whose current flows at a rate never less than 2·5 m. per second and is sometimes as high as 3·5 m. per second, presented many difficulties. Swedish hydraulic engineers have in recent years developed a special technique in such construction. Nearly all the dams and regulating weirs or barrages that have been built in connection with hydro-electric power plants in Sweden since the early years of the present century have been in swift-flowing rivers having a rocky bed and often in the midst of turbulent rapids. Much ingenuity and skill have been shown in overcoming the difficulties of construction in such conditions, and the Vargön cofferdam is an outstanding and instructive example of this class of under-water work. It was, of course, impossible for divers to work under water except within the cofferdam or a caisson or under the lee of the upstream face of the cofferdam after that had been put in position. It was decided to make use of certain parts of the concrete structure of the power station on the upstream side as supports for the upstream face of the steel cofferdam. Portions of the concrete foundations were therefore constructed by means of three caissons. These were formed in plan so as to be suitable for incorporation in the side walls of the intakes in the permanent work. The caissons were constructed on shore and, when ready, each was suspended from staging between two barges coupled together—Fig. 10. The barges were towed upstream through the rapids and moored in the correct position for sinking the caisson. After the caisson had been sunk, Fig. 11, close junction with the rock bottom was secured by means of short sheet piles attached to the bottom edges of the caisson walls. Divers were then able to descend and carry out preparatory work on the rock bottom inside the caisson before concrete was deposited. After the three caissons had been filled with concrete placed under water, the upstream part of the concrete roof over the intakes was built upon the concrete in the caissons so as to make the latter stable against the pressure from the cofferdam wall in front of the intakes. This part of the cofferdam consists of broad flange rolled steel joists, 380 m. deep, resting on the rock bottom, as shown in Fig. 12, and spaced from 0·65 m. to 0·75 m. apart, with a grillage of flat-bottomed rails placed horizontally between the joists and the outer face of interlocked steel sheet piles. All this steel work had to be placed in position without the assistance of divers. Each of the inclined rolled steel joists was secured to the granite rock by a dowel bar of drill steel bearing against a flange of the joist and drilled into the rock from above water. These dowels are shown in the section Fig. 12 and in the view Fig. 13, where workmen are seen clipping a bar to the joist before beginning to drill by compressed air. Fig. 1 on page 448 is a view of the inclined joists of the cofferdam being placed in position in front of the intake openings. At the back of the inclined joists are two heavy horizontal built-up steel girders, 2·50 m. deep, extending across the intake openings, which were placed in position before the cofferdam face was constructed. These are shown in Fig. 12, and that in the western intake is seen in the view—Fig. 3—taken from inside the cofferdam. The steel struts at the back of the horizontal beam were put in place and the subaqueous concrete supports were cast as soon as smooth water conditions had been secured by the placing of the upstream sheet piling. The view—Fig. 2—shows the cofferdam seen from the west directly after it had been pumped out in January, 1932. On the left of the view are seen the concrete piers which had been built inside the caissons and, supported by them, the upstream portion of the roof of the intakes. A view of the timber shuttering used for the construction of this part of the roof and the steel arches supporting it is reproduced in Fig. 4.

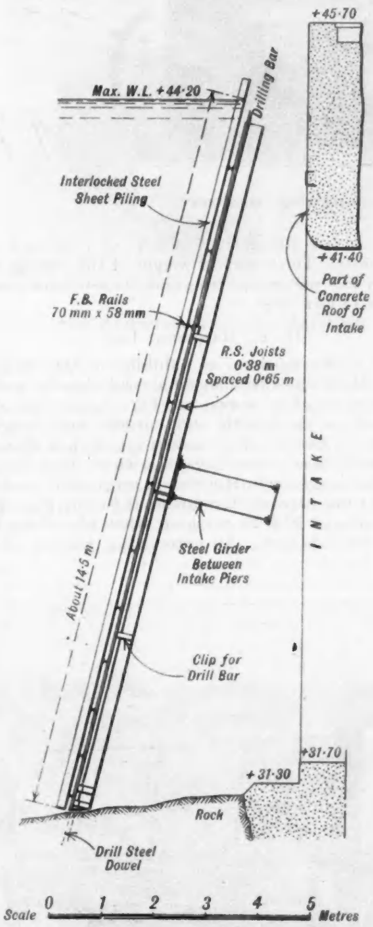

Fig. 12—Section of Upstream Cofferdam

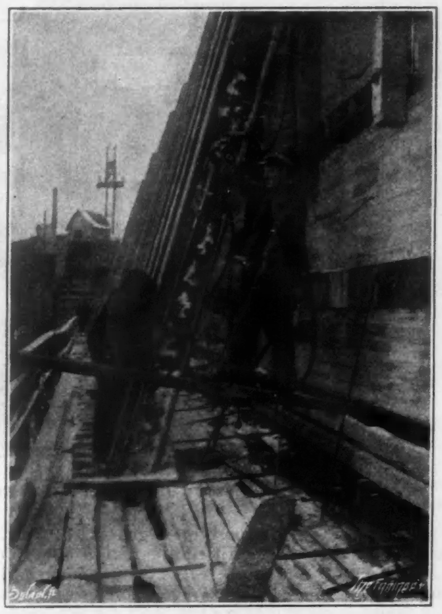

Fig. 13—Upstream Cofferdam. Drilling in Rock for Anchor Dowels—May, 1931

On the downstream side the cofferdam was built of heavy bents or trestles of rolled steel sections, spaced from 6·75 m. to 8·0 m. apart, which were lowered on to the rock bed and afterwards secured in position by concrete deposited under and around the feet of the frames. The trestles support horizontal rolled steel joists against which the interlocked steel sheet piling rests. This part of the cofferdam—Fig. 14—has a maximum height of 17 m. and was to a great extent built in still water under the lee of the previously constructed upstream cofferdam. The other cofferdams used on the works, including most of the east and west walls of the power station cofferdam, are built of timber. The advantage of the steel construction used for the upstream and downstream cofferdams is mainly that it allows the steel sheet piling to be set very close to the permanent structure of the power station where the water is comparatively shallow, as will be seen by reference to the contours shown in the plan—Fig. 8. The building of the power station cofferdam was begun in January, 1930, and completed in January, 1932.

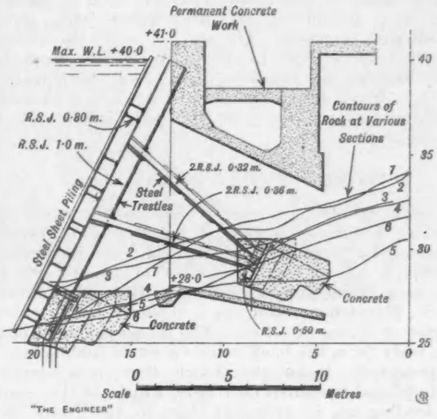

Fig. 14—Downstream Cofferdam—Typical Cross-Section

(*To be continued.*)

The Public Works, Roads, and Transport Exhibition.

No. I.

The Public Works, Roads, and Transport Exhibition, which opens in the Royal Agricultural Hall, Islington, on Monday, November 13th, for six days, until the 18th, promises to be one of the best ever held. The list of exhibitors is, we believe, longer than that for past Shows, and our preliminary investigation of the machinery and plant which they propose to exhibit suggests unusual interest. There may not be many very radical changes or novelties, but there is evidence of distinct improvement in designs and types. We start below our descriptions of some of the more prominent exhibits.

Karrier Motors, Ltd.

There will be three vehicles on the stand of Karrier Motors, Ltd., of Huddersfield, two refuse collectors, and the street sweeper illustrated by Fig. 1. The refuse collectors are both driven by 10/30 H.P. petrol engines, and have bodies equipped with sliding steel covers, of 5 cubic yards and 6 yards capacity respectively.

The sweeper, which we illustrate, is driven by a 26 horse-power, four-cylinder petrol engine, and has a body capacity of 90 cubic feet, while the water tank at the back will hold 150 gallons. It will sweep a width of 7ft., and when working travels at from 3 to 6 miles per hour, but can run at 12 miles per hour in getting to its work.

The road brush, which is 2ft. in diameter, is of a special curved type—curved, that is, in plan, but straight so far as road contact is concerned—which not only prevents the "trail" which is formed when an angular-set straight brush is employed, but also improves the sweeping generally. The brush shaft consists of seven hexagon steel tubes mounted on a non-revolving steel shaft, bent to give the required curvature. Each tube, mounted on roller bearings, is geared to its fellow so that transmission may be maintained throughout the entire length, and the whole assembly forms a compact unit which allows the changing of brushes to be carried out in a similar manner as with a straight broom, each brush centre having a hexagon core. The brush centres are fitted with "cup and ball" ends, by means of which a varying alignment is obtained without leaving a gap between the individual brush sections. The brush, which is put into action by means of a foot-operated dog clutch, is driven by totally enclosed bevel gearing, power being transmitted from the front of the gear-box by means of a worm and wheel. A hand lever situated alongside the driver enables

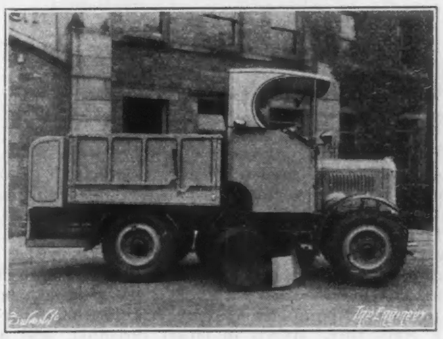

Fig. 1—Street Sweeper—Karrier

the brush to be raised or lowered at will, whilst its pressure against the road is regulated as required by means of small hand wheels. A spring-loaded balance gear gives an independent balance to each end of the brush, and so ensures freedom of movement when operating upon roads of various camber.

At the end of the road brush, on the off-side, is a quick-lifting pan arrangement, hinged to a casing and operated by cam gear. The casing contains three rotors placed one over the other, and each embodies three vanes of rubber. The intermediate rotor revolves in the opposite direction to the other two, refuse being carried from each rotor in turn to the body of the machine. On being caught by the bottom rotor, refuse is carried from this to the middle and then to the top rotor, which finally throws it into the body. Centrifugal force causes the refuse to shoot with considerable force to the extreme rear, thus preventing the discharge opening from becoming clogged. It also greatly facilitates the distribution of the load. When the body is fully loaded, the brush is raised and the machine is then driven off to the dump. After withdrawing the draw-bolts of the door, the body is side-tipped by the driver.

Walker Brothers (Wigan), Ltd.

There will be only one vehicle on the stand of Walker Brothers (Wigan), Ltd., Pagefield Works, Wigan, the household refuse collector illustrated by Fig. 2. It is one of a fleet of twenty which are now being supplied to the Borough Council of St. Marylebone, and has a capacity for 15 cubic yards, or 3 tons of refuse. The refuse is loaded into the body from the back, where a set of folding steps is provided. Inside the vehicle there is a barrier, or bulkhead, mounted on rollers, which, at the start of loading up, is arranged close to the front end of the body and is gradually drawn back as the body is filled with refuse in front of the bulkhead. This gives the men a clear floor to work on while they pile up the refuse to the maximum height. The carrying capacity is thus used to the utmost, while the dustbins are emptied under cover and their contents are not spilled about the road. An effective system of ventilation is provided by the clerestory roof. The chassis is designed to carry a total load of 5 tons, and is driven by an engine of 20–46 horse-power. The clutch is of the single dry-plate type, and the gear-box gives four speeds forward and a reverse. The engine, gear-box, and change-speed gear are all built up as one unit, and the back axle is of the Kirkstall worm-driven type. There are four-wheel brakes of the Lockheed hydraulic type, which are both hand and foot-operated, and the Woodhead springs have leaves each grooved for separate lubrication. The tires are 27in. by 6in.

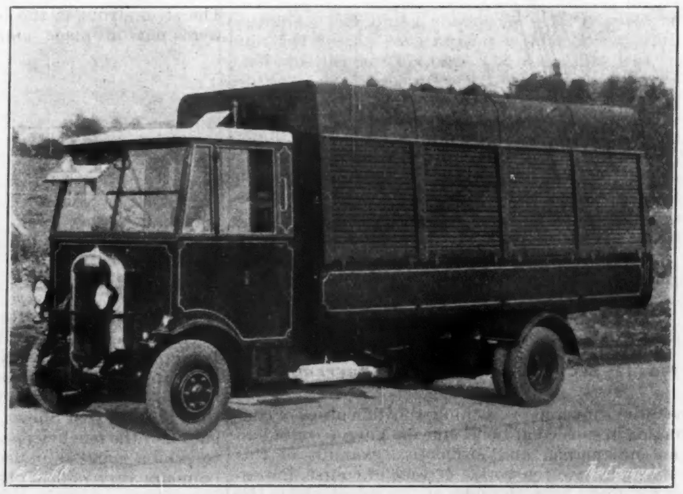

Fig. 4—12 Cubic Yard Refuse Collector—Thornycroft

Ruston and Hornsby, Ltd.

A variety of contractors' plant, ranging from a crude oil locomotive to small petrol engines, will be displayed by Ruston and Hornsby, Ltd., of Lincoln.

The locomotive, which we illustrate in Fig. 3, has a two-cylinder Lister fuel oil engine of 16–20 H.P., and will be demonstrated working on a short length of track, so that the ease with which the gears can be changed may be appreciated by visitors. The gear-box gives three speeds in either direction, and is operated by one lever in conjunction with a clutch. The final drive is taken to the two axles by means of chains, and radius rods are provided to maintain the tension in the chains regardless of the rise and fall of the axles in the horn plates.

There will also be a roller for grass work—aerodromes, sports fields, &c.—of 2½ tons normal weight, driven by a crude oil engine, and giving a rolling width of either 4ft. 1in. or 6ft., according to the placing of the rear rolls on their axles. This machine has four travelling speeds in either direction and has a double clutch, which gives immediate reversal without it being necessary to disengage any of the gears.

The pumping equipment shown will include a 4in. diaphragm pump driven by a Ruston petrol-paraffin engine through a roller chain and spur gearing, a portable 4½ H.P. oil engine centrifugal set, and some hand pumps.

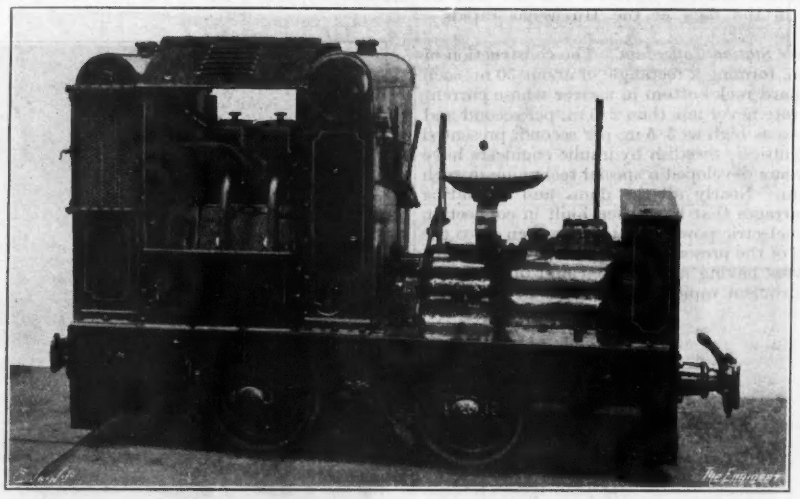

Fig. 3—16/20 H.P. Oil Engine Locomotive—Ruston

Plain straightforward oil engines will be exemplified in a 3 B.H.P. set, which is made in sizes ranging from 1½ up to 6¼ H.P.; a transportable engine of 64 B.H.P., mounted on skids so that it can be moved about on rough ground; and a 17 B.H.P. stationary horizontal engine, running at 350 revolutions per minute. This engine is capable of running on very low grades of fuel oil and its internal arrangements are to be demonstrated by a sectionalised scale model. There will also be an example of the makers' form of vertical tubular boiler for working pressures up to 120 lb. per square inch, with a looking glass arranged in the fire-box, so that the disposition of the heating surface can be easily seen.

J. I. Thornycroft and Co., Ltd.

The trend towards the more hygienic collection of household refuse will be well exemplified on the stand of J. I. Thornycroft and Co., Ltd., Smith-square, Westminster, where the main exhibit is to be the 12 cubic yard refuse collection vehicle, illustrated by Fig. 4.

This machine is composed of a standard Thornycroft 2-ton chassis fitted with Eagle bodywork, and a movable floor by the Transport Engineering Company. The floor is interesting in that it is more or less in the form of a conveyor to which there is attached a bulkhead. The idea is that the refuse should be tipped into the body with the bulkhead at the front end and the floor then drawn back, so as to squeeze the refuse against the tailboard. Such a process may be repeated several times, and then, finally, at the dump the tailboard is let down and the movable floor and bulkhead carry the load out at the back, without it being necessary to tip the body. The floor is built up of hinged steel slats and is operated by power taken from the gear-box, so that the refuse is subjected to a good squeeze by the bulkhead and the capacity of the body thus used to the utmost. The floor slats are attached to roller chains, which are driven by chain sprockets on a countershaft. The body, which is made of steel throughout, is 15ft. long by 6ft. 6in. wide, with a roof 5ft. above the floor level. The tailboard is hinged at the top and has a ratchet device which retains it in the open position during the discharge of the contents.

The chassis, as we have said, is a standard 2-ton Thornycroft, and has a wheel base of 13ft. 4¼in., while the track is 5ft. 4⅞in. The engine, of 38 H.P., has four cylinders, 3¾in. in diameter by 5in. stroke, and works in conjunction with a four-speed gear-box. The standard ratio from engine to back wheels is 6·25 to 1, but alternatives of 5·75 or 7·75 to 1 may be adopted. The standard weight of the chassis with 27in. by 6in. pneumatic tires and the usual accessories is 1 ton 18 cwt. 2 qr.

H. R. Marsden, Ltd.

One of the most novel exhibits on the stand of H. R. Marsden, Ltd., Meadow-road, Leeds, will be the stone-breaker shown in Fig. 5. It has been designed to deal with the hardest and toughest materials. One of these machines, with a 24in. by 5in. mouth, was recently tested with an exceptionally hard and tough rock, Hornfelsed greenstone, and was proved to be capable of reducing it to ¾in. and under at the rate of 10 tons per hour when absorbing 13·5 brake horse-power. An interesting feature of the frame of this machine is the method of ribbing which is arranged and proportioned to offer adequate resistance to all bending and shearing stresses, and to the sudden shocks this type of machinery is subjected to. The trouble sometimes caused by small fragments of stone lodging between the jawstock and frame is also provided against. The fixed jaws are positively locked, and a false back behind the fixed jaw prevents any possibility of ridges being formed on the frame by the jaw at this point. The excentric shaft is a solid forging, turned and ground, and revolves in four self-aligning heavy-type roller bearings. An elaborate system of labyrinth seals affords protection from dust. A power saving of approximately 60 per cent. in starting and 10 per cent. when under load is said to be effected by these anti-friction bearings as compared with bearings of white metal. Stability and the absence of vibration are noticeable qualities of the machine, and the low, "squat" appearance, palpable in our illustration, gives an impression of latent strength.

Although the Mitchell electric vibrating screen, which is to be shown on this stand, has a generally smaller screening area than several other types, the capacity is said to be greater than any other vibrating screen of equal size. It is peculiar inasmuch as it does not depend upon belts, cams, levers, chains, or any unrelated moving parts for operation. The vibrator consists of a motor enclosed in a dust and water-tight housing. A ball is located in a special cage at each end of the rotor shaft, the balls being placed at an angle of 180 deg. in relation to each other. The rotor shaft revolves at 3600 r.p.m., and the unbalanced load of the balls against hardened steel races in the housing, combined with the gyroscopic action of the rotor, imparts an extraordinary rotary action by which the material is almost fed back on itself.

A clamp around each end of the vibrator housing holds the side plates which carry the screen cloth. Live rubber absorbers are used to damp out vibration from the frame carrying the vibrator, and such is their efficiency that a pencil may be placed upright on the supporting framework and remain steady. The vibrator is designed for 220, 440, or 550 volts, two or three phase, 50 or 60 cycles A.C., and the power absorbed is slightly under 0·75 B.H.P.

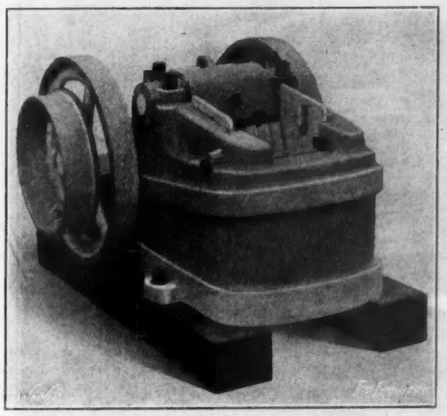

FIG. 5—STONE-BREAKER—MARSDEN

An example of each of two types of stone-breakers is also to be shown. The "X" type is operated by a single toggle and an underslung lever, the coupling to the crank shaft being made by a built-up connecting-rod. The arrangement permits of an exceptionally low centre of gravity with resultant steadiness of motion. The lever is pivoted on a machined cast steel gudgeon, its action being similar to a roller bearing. The "H" type is a modernised version of the original "Blake" stone-breaker, first produced in Europe by this firm over seventy years ago. It has the usual straightforward double-toggle mechanism actuated by an excentric shaft through a pitman, and the number of working parts is kept at a minimum.

JOHN ALLEN AND SONS (OXFORD), LTD.

There will be two stands under the name of John Allen and Sons (Oxford), Ltd., a firm with works at Cowley, near Oxford. On one in the main hall of the Exhibition there will be shown the new trench-excavating machine illustrated by Figs. 6 and 7, and some other light road-making machinery there, whilst a grader and a scraper will be exhibited in the gallery.

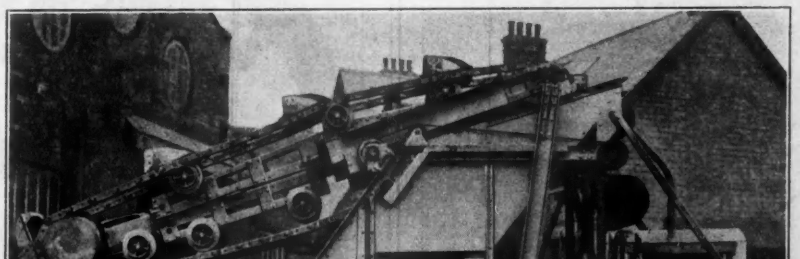

FIG. 6—TRENCH EXCAVATOR—ALLEN

The excavator, it will be seen, is mounted on chain tracks, and is capable of digging trenches from $15\frac{1}{2}$in. up to 42in. wide, and to a depth of 14ft. On the main frame there is mounted a boom carrying the excavating chain. This boom is telescopic and can be extended in steps of $12\frac{1}{2}$in. It can also be moved transversely across the main frame so that the trench is dug in the centre or on either side. The boom is raised and lowered by cables, which are operated by worm gearing that locks it in the working position and holds the buckets up to their work. The buckets, which are cast in alloy steel, are attached to two flat-link chains, and pass a cleaning device on their upward travel, so that all the soil they bring up is discharged and falls on to a transverse belt conveyor, which dumps to either side. This conveyor can be quickly shifted to clear any obstruction as the machine progresses. The machine is driven by a four-cylinder petrol engine of 36 horse-power, and has a travelling speed of 1·66 miles per hour. The digging speeds range from 11in. to 139in. per minute. The changes in speed are effected by means of a gear-box controlled by one bank of levers, which are all under the hand of the driver, so that he can adapt the running of the machine to the immediate conditions of the soil being trenched. These gears are all totally enclosed and run in an oil bath.

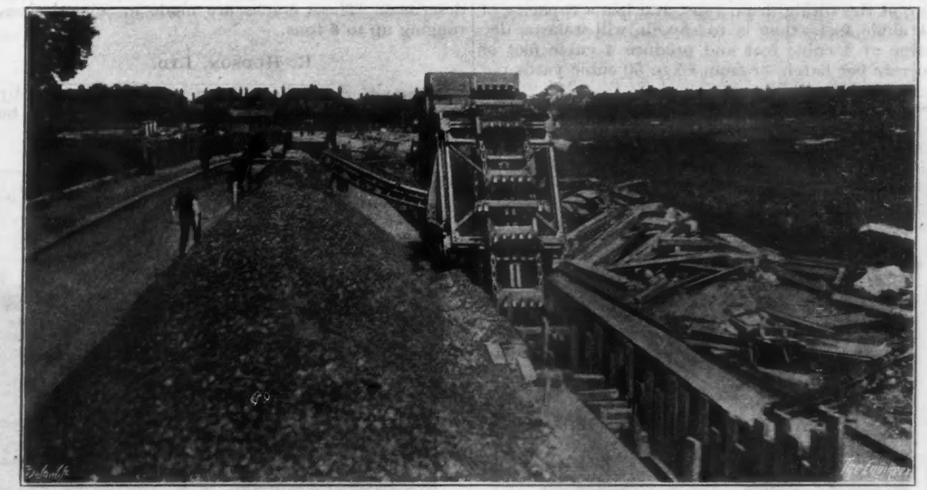

FIG. 7—TRENCH EXCAVATOR AT WORK—ALLEN

There is to be at the Exhibition a smaller machine of the same type, which will make trenches from 6in. to 12in. wide and 4ft. deep, a light roller driven by a new type of water-cooled engine, and a motor scythe.

WALLIS AND STEVENS, LTD.

Several road rollers will be exhibited on the stand of Wallis and Stevens, Ltd., Basingstoke, and will include that shown in the engraving, Fig. 8, which is driven by a compression ignition oil engine. Other exhibits comprise an 8-ton steam roller with the automatic cambering rear axle which we have described in the past; two lighter rollers, driven by oil engines; a road scarifier; a cold emulsion sprayer; and a chipping distributor.

The roller shown in Fig. 8 is equipped with a three-cylinder compression ignition engine, giving 28 B.H.P. when running at 1050 revolutions per minute. It has cylinders $4\frac{1}{8}$in. bore by 6in. stroke, and has a cylinder head and exhaust valve lifter which enable it to be started easily from cold without ignition or preheating devices. The atomisers or fuel jets are of the self-cleaning type, and the fuel pump has a separate plunger for each atomiser. The transmission from the engine is taken through a clutch to a four-speed gear-box, and thence through two reversing clutches and a reducing gear to a differential shaft. From this shaft the final drive is by spur gears direct on to both hind rolls. The differential gear can be locked from the driving position, while the roller is in motion. The road speeds, with the engine running normally, are 4, $2\frac{1}{4}$, $1\frac{1}{3}$, and $\frac{7}{8}$ m.p.h. respectively in both directions. The engine and gear-box are built as one unit, and can be readily taken out of the main frame, for which purpose large doors are provided in the side, as shown in Fig. 9. The rear axle is of the automatic cambering type, and the front roll has an underslung carriage, so that it can easily adapt itself to the contour of the road surface. The rolling width is 6ft. 4in., the hind rolls are 4ft. 6in. in diameter by 2ft. 1in. wide, and the front roll 3ft. 9in. by 3ft. The wheel base is 10ft., and the turning circle of 15ft. outside radius.

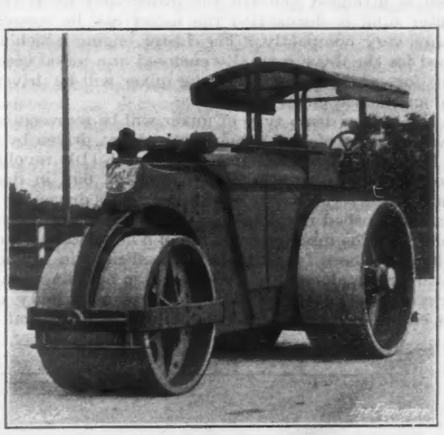

FIG. 8—$10\frac{3}{4}$-TON OIL ENGINE-DRIVEN ROLLER—WALLIS

One of the lighter rollers to be exhibited on this stand weighs $2\frac{1}{2}$ tons, and is equipped with $14\frac{1}{2}$ B.H.P. four-cylinder, side-valve, petrol engine, running at 1150 revolutions per minute. The transmission is through a four-speed gear-box, giving road speeds from 1 up to 4 m.p.h., and can be arranged to include a differential gear. The final transmission is through spur gearing. The rolling width can be varied from 3ft. $6\frac{1}{2}$in. to 4ft. $2\frac{1}{2}$in., by reversing the hind rolls on the axle.

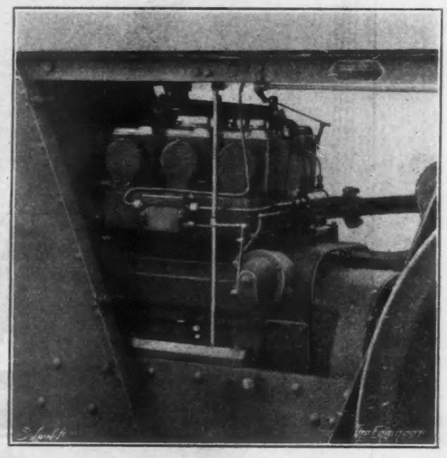

FIG. 9—ENGINE OF $10\frac{3}{4}$-TON ROLLER—WALLIS

RANSOMES AND RAPIER, LTD.

There will be an extensive display of contractors' machinery on the stand of Ransomes and Rapier, Ltd., Ipswich, including four concrete mixers, one of which we illustrate in Fig. 10, a builder's hoist, a mobile crane (see Fig. 11), and a 20 horse-power oil engine locomotive. There will also be available for inspection a 3-ton Ransomes-Rapier-Thornycroft lorry crane, capable of lifting 3 tons at a radius of 9ft. 6in., or 1¼ ton at 18ft., and able to travel at speeds up to 20 miles per hour, and a 6-ton lorry crane of much the same type.

The concrete mixer which we illustrate is, it will be seen, of the tilting drum type, and has a capacity of 6/4 cubic feet—that is to say, it will take a dry charge of 6 cubic feet and produce 4 cubic feet of concrete per batch, or from 45 to 50 cubic yards per eight hours' shift. It weighs just over a ton. All the gear is arranged beneath the drum, and when the water tank is dismantled the mixer can be stowed away very compactly. The Lister engine which is used for the drive is totally enclosed in a metal case, but for exhibition purposes the mixer will be driven by an electric motor.

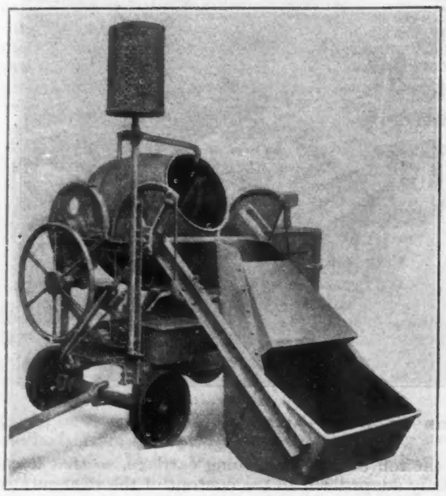

FIG. 10—TILTING DRUM CONCRETE MIXER —RANSOMES

The rotary drum type of mixer will be represented by a machine of 10/7 cubic feet capacity, driven by a 9 H.P. Lister petrol engine, running at 1100 revolutions per minute. It has a drum 4ft. 6in. in diameter, which runs on two raceways and is driven by a central toothed ring at a speed of 16 revolutions per minute. The mixing blades are of a new lattice type, which has been found to be very efficient in mixing both large and small aggregate, and in handling semi-dry or wet mixtures. The skip has a capacity of 14 cubic feet, and is lifted by means of ropes and a Spanish windlass type of hoist operated by the engine. Water is supplied to the mix by an automatic tank of a type which we have described in the past. The machine weighs 46 cwt., and has overall dimensions of 8ft. 11in. long by about 8ft. 4in. high, and a width, when travelling with the skip up, of 7ft. 6½in.

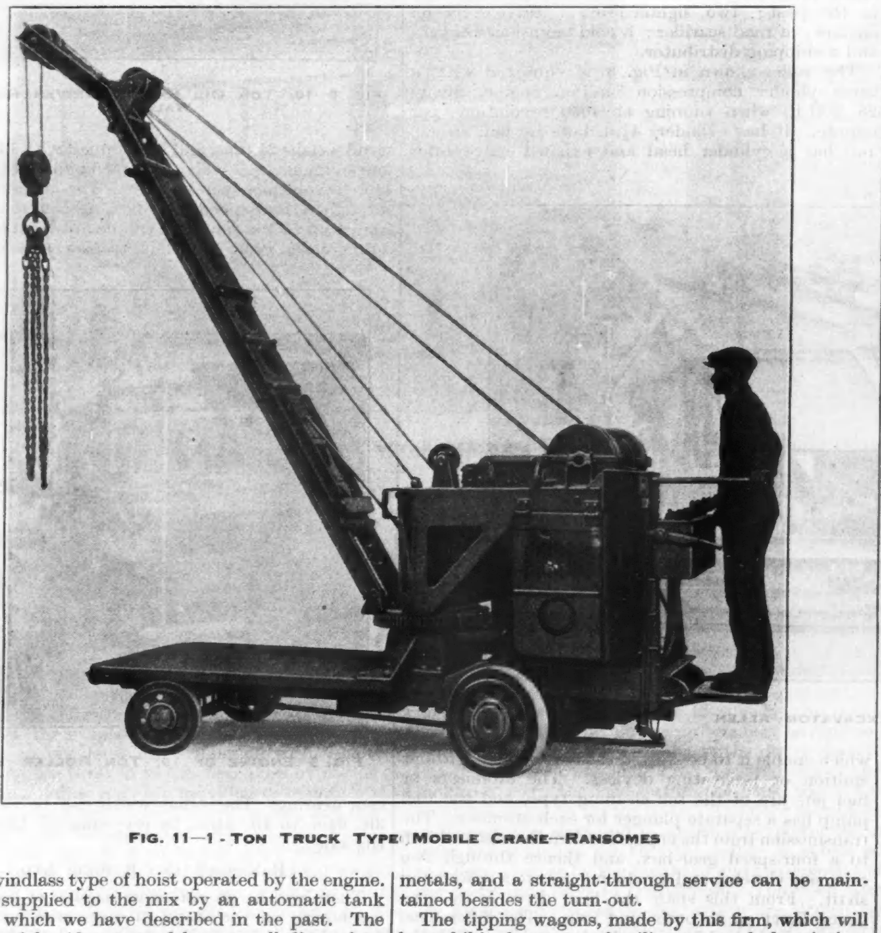

FIG. 11—1-TON TRUCK TYPE MOBILE CRANE—RANSOMES

The builder's hoist is a light steel framework, which can be either a stationary unit or mounted on wheels, up which a skip is hoisted by a 5 H.P. Lister engine. It is capable of lifting 10 cwt., at a speed of 85ft. per minute. The mobile crane, which we illustrate in Fig. 11, is of 1 ton capacity, and is operated on the petrol-electric principle, which we have already described. These cranes are made in several sizes, ranging up to 6 tons.

R. HUDSON, LTD.

Although the light railway equipment made by R. Hudson, Ltd., 28A, Bond-street, Leeds, must be familiar to most civil engineers, we think that the portable switch seen in the foreground of Fig. 12 is worthy of attention. It is, as will be gathered from the illustration, built up of a few pressings made of mild steel plate, and, literally, requires no more installation than to be put down on the metals where a turn-out is required. By turning it end for end, it can be used for a turn either to the right or the left, and the maximum lift it imposes on the rolling stock as it passes over is only 1in. It is obvious that there is no necessity to cut the railway metals, and a straight-through service can be maintained besides the turn-out.

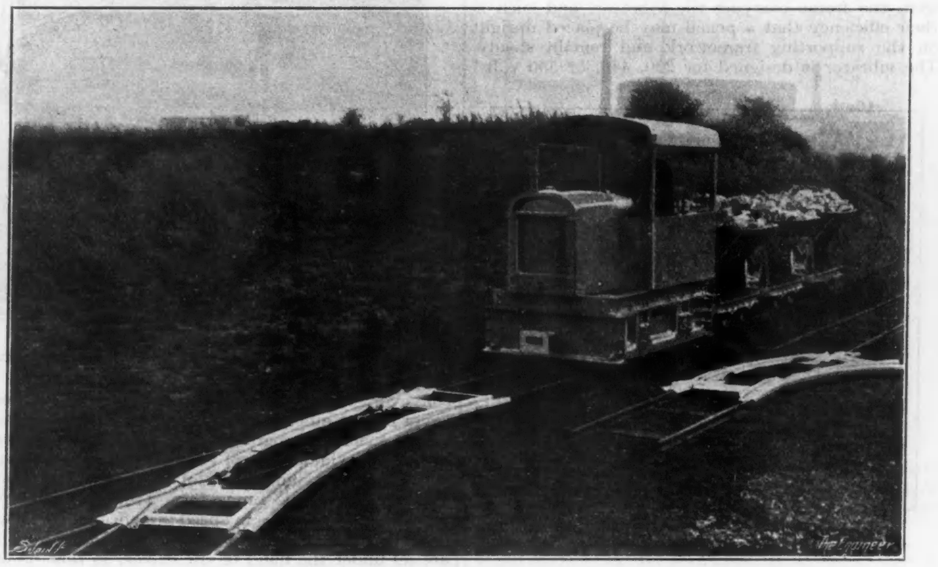

FIG. 12—LIGHT RAILWAY SWITCH AND LOCOMOTIVE—HUDSON

The tipping wagons, made by this firm, which will be exhibited are too familiar to need description, as, also, is the oil engine locomotive. In conjunction with R. H. Neal, Ltd., this firm is showing a ⅓ cubic yard concrete pouring skip.

THE GENERAL ELECTRIC COMPANY, LTD.

Among the novelties to be exhibited by the General Electric Company, Ltd., of Magnet House, Kingsway, Westminster, there will be the so-called "bollard" for traffic direction purposes, which is illustrated by the sketch, Fig. 13. It is essentially a post, with a cast iron foundation, a stalk of wrought steel tube, and a cast iron cap. One side of the tubular stalk—that facing the traffic—is cut away, and in the space so provided there is arranged a series of white enamelled reflectors, which are illuminated by a lamp just under the cap. This lamp also shows a light behind a coloured window at the top, which may be red or amber according to the exigencies of the local affairs. The exhibit will also include a typical standard lamp for street lighting, and some examples of Osira flood-lighting. This system

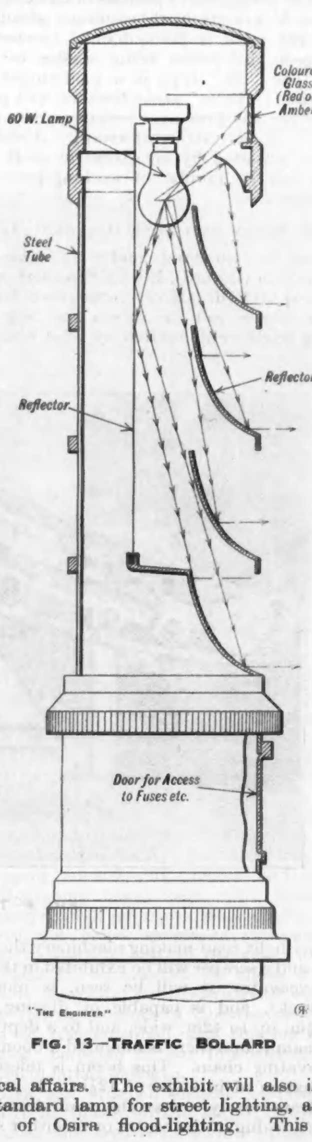

FIG. 13—TRAFFIC BOLLARD

of lighting is notable on account of the fact that it gives a very good illumination in the direction in which traffic is proceeding, while oncoming vehicles are not incommoded by glare.

R. A. Lister and Co., Ltd.

The firm of R. A. Lister and Co., Ltd., Dursley, Gloucester, will, we believe, have the distinction of staging the smallest powered compression-ignition oil engine yet made on a commercial scale. It is illustrated by Fig. 15, is of only 3 horse-power, and is, naturally, of the single-cylinder type. It runs at a speed of 600 revolutions per minute, and is said to have a fuel consumption, on full load, of less than 1½ pints of oil per hour. Among the other engines to be exhibited there will be the two-cylinder 14 H.P. set that was described and illustrated in The Engineer of October 27th, of which the outstanding feature is the ability to change the compression ratio at starting to get a good firing temperature, and then reduce it for normal running. A third engine of much the same type has three cylinders and develops 27 horse-power when running at 1000 revolutions per minute, or 31 horse-power at 1200 r.p.m.

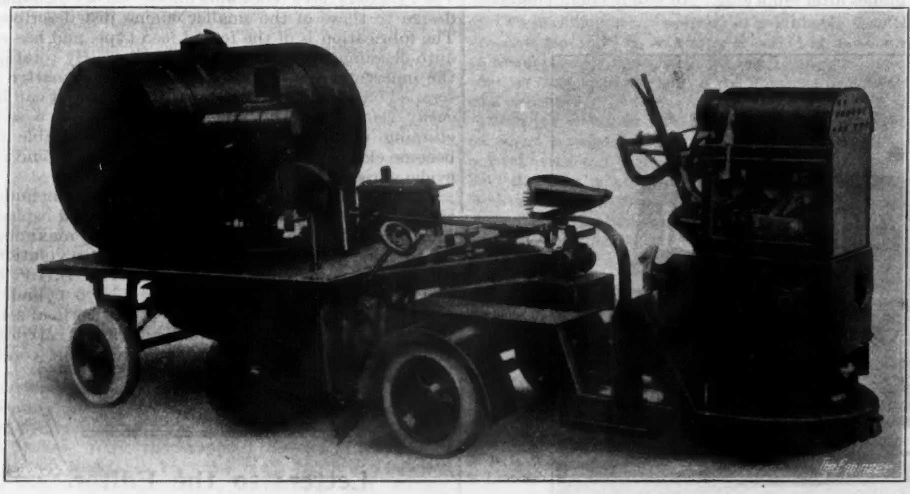

Fig. 14—Auto-Truck Cleansing Equipment—Lister

There will be also on this stand several petrol engines ranging upwards from 4 horse-power to 12 horse-power. The latter engine is arranged in a sheet metal casing, and is of that type which will be found in several parts of the Exhibition for driving contractors' machinery.

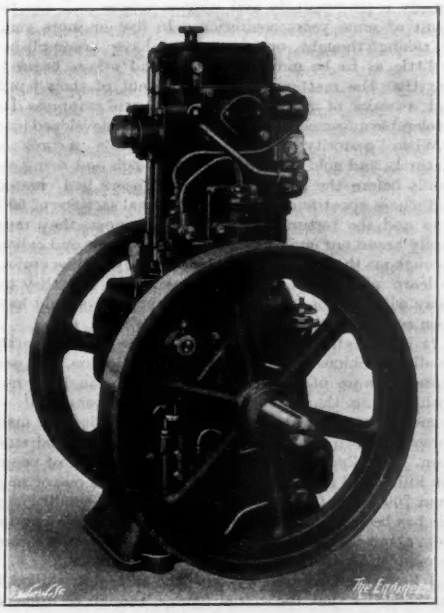

Fig. 15—3 H.P. C.I. Oil Engine—Lister

There will also be shown an adaptation of the Lister truck for working a street cleansing equipment, which is illustrated by Fig. 14. In this case, it will be seen, the truck is used to haul a trailer that comprises a road sweeper and sprinkler. The broom of the sweeper is driven by a separate 1½ horse-power engine, which also drives a pump to feed the sprinkler. The tank has a capacity of 145 gallons, and the width of the ground swept is 5ft. The equipment is capable of working up a gradient of 1 in 15. The truck is also applicable to the hauling of a refuse collecting trailer consisting of a 7 cubic yard capacity end-tipping body constructed of timber reinforced with steel angle pieces and mounted on a steel channel stepped-up frame. Sliding metal covers are fitted in two sections on each side. The loading height is 4ft., the tipping angle is 45 deg., and the body is tipped by a robust 2½in. diameter telescopic tipping gear with winding mechanism which ensures easy tipping.

Marshall, Sons and Co., Ltd.

The principal exhibits on the stand of Marshall, Sons and Co., Ltd., Gainsborough, will be two road rollers, both driven by oil engines, of 4 tons and 10 tons weight respectively. The latter is illustrated by our Fig. 16.

With the first of these machines we dealt in connection with the Royal Agricultural Show, in our issue of July 1st, 1932, and its characteristics are consequently familiar to our readers. The 10-ton roller, which we illustrate, is driven by a three-cylinder Blackstone compression-ignition engine of 30 B.H.P., which, it is claimed, will effect a saving as regards fuel cost of from 75 to 85 per cent. compared with a petrol engine. The engine is fitted with a decompression device, with the help of which it can be easily started from cold by hand without the use of ignition cartridges or electric hot-wire plugs. From the engine the power is transmitted through two Ferodo-lined clutches that give a forward and reverse effect by means of bevel gears. Thence there is an arrangement of three-speed gears, giving road speeds of 1·25, 1·75 and 3·3 miles per hour. A differential gear is incorporated in the final shaft of the gear-box, which is totally enclosed and filled with oil. The final drive to the road rolls is by a spur gear pinion and an internal gear ring bolted directly to each hind roll. There is a locking arrangement to put the differential gear out of action which can be operated from the driver's station. A foot-operated brake is provided on one of the intermediate shafts, and is so arranged that it does not go out of action while the speed gears are being changed. There is another brake, of the hand screw-down type, acting on the back rolls. Steering is effected by an inclined hand wheel coupled by means of bevel gears to a worm operating a segment connected directly with the steering head. The main frame, it will be seen, takes the form of deep steel plate girders, which are strongly braced together. Between the frames at the back there is a built-in tank, which may be used either for water for spraying purposes, or as an extra fuel tank. The main fuel tank is on the dashboard. The machine is equipped with a scarifier of the Allen type, which can be traversed across the back so as to attack the whole width of the road without it being necessary to turn round the roller. The diameter of the hind rolls is 5ft., and their width 20in. The front rolls are 3ft. 9in. in diameter by 4ft. wide.

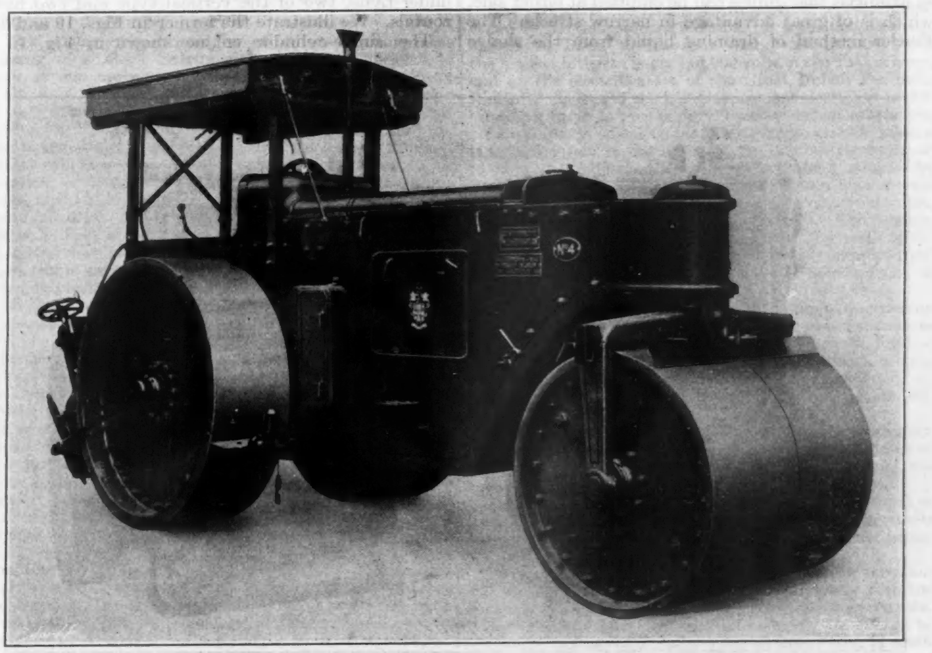

Fig. 16—10-Ton Oil Engine-Driven Road Roller—Marshall

The Lead Wool Company, Ltd.

The name of the Lead Wool Company, with offices and works at Snodland, in Kent, is generally associated with various forms of material for caulking the joints of cast iron pipes, and its stand will have a considerable display of this kind, but such materials are too familiar to engineers to need further description. The air-compressing set illustrated by Fig. 17 is, however, somewhat novel, and is, naturally, associated with the laying of main pipe lines.

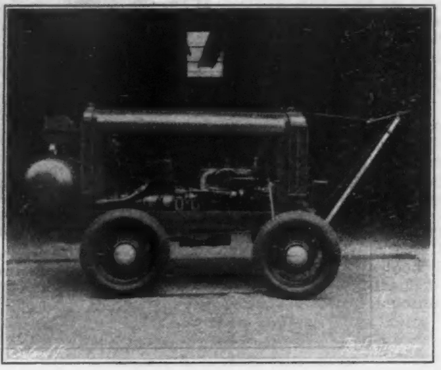

Fig. 17—Portable Compressor—Lead Wool

It comprises two Ford units, one being a four-cylinder engine, with cylinders 3⅞in. diameter by 4¼in. stroke, and the other, to which it is directly connected, a corresponding Ford engine with a special cylinder head which embodies plate valves for the inlet and discharge of the air. This cylinder head is practically the only deviation from standard Ford practice, and, as a consequence, the maintenance of spares for replacement purposes is minimised.

The compressor is capable of delivering 115 cubic feet of free air per minute against a pressure of 100 lb. per square inch, and is separated, as regards the cooling system, from the engine. Each unit has its own cooling system, and so can be worked to the best advantage. The coil ignition system has been dispensed with and a magneto impulse starter fitted for getting easily under way. The engine is equipped with a governor which controls the speed within narrow limits from no load to full load. The complete equipment weighs only 22 cwt., and measures 8ft. 9in. long by 4ft. 6in. high, and has a width, over the wheels, of 4ft.

John Fowler and Co. (Leeds), Ltd.

On the stand of John Fowler and Co. (Leeds), Ltd., will be exhibited an oil-engined road roller and a motor gully emptier, the latter of which is similar to that shown in Fig. 18.

The roller weighs 8 tons and is of an entirely new design. The engine fitted in it is a new Fowler 33 H.P. three-cylinder engine, in which the fuel pump, governor, and, in fact, the entire fuel injection system, is totally enclosed, thus excluding grit and dirt, and thereby reducing wear and tear and liability to stoppages. This system of totally enclosing the important working parts is desirable under any conditions, but particularly in connection with road rollers where dust and grit are present to an exceptional degree. At the same time the method adopted does not interfere with the accessibility. The engine is started by hand, and a special device is fitted for decompression, which operates automatically. The roller is equipped with four road speeds, direct overhead steerage, quick reverse, foot and hand brakes, &c. Both front and rear wheels have steel rims, which assist the roller on gradients and give longer life. Differential gear is fitted, and can be locked from the driver's footplate when there is any tendency to slip. All the controls for the roller are so arranged that they can be operated by the driver from his seat, and special attention has been paid to the driver having a clear view of the road, both from the point of view of the work to be done and passing traffic and pedestrians.

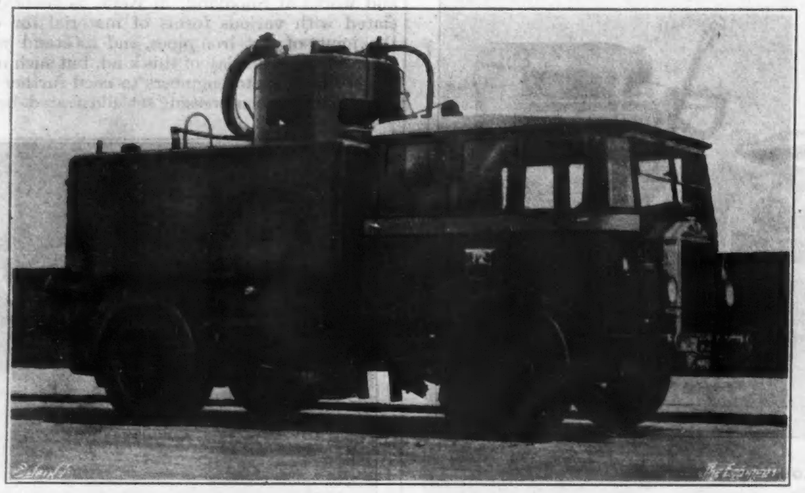

FIG. 18—MOTOR GULLY EMPTIER—FOWLER

The motor gully emptier—see Fig. 18—has been built to the order of the Wakefield Corporation, and is fitted on an "Albion" chassis. It is equipped for gully emptying, street watering, street washing, kerb washing, channel damping, and sewer flushing. It is so arranged that gullies can be emptied at either side, which is of great advantage in narrow streets. The Fowler method of draining liquid from the sludge tank enables a greater number of gullies to be emptied before it is necessary to discharge the refuse, and owing to the large capacity of the tanks, every gully emptied can be sealed with clean water.

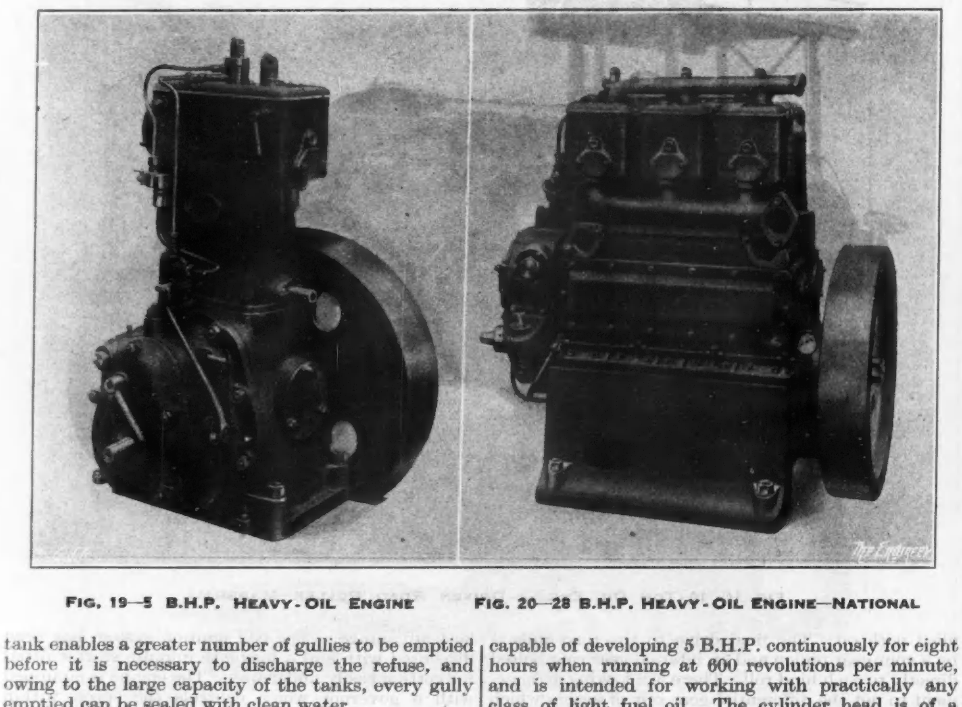

FIG. 19—5 B.H.P. HEAVY-OIL ENGINE FIG. 20—28 B.H.P. HEAVY-OIL ENGINE—NATIONAL

The main tank is totally enclosed, with separate sections for the sludge and resealing water, and is fitted with baffle plates to prevent surging of the water. A vacuum chamber is mounted above the sludge tank, the necessary vacuum being obtained by means of an exhauster driven from the engine gear-box, and controlled from the driver's cab. The contents of the vacuum tank are transferred to the main sludge tank by the opening of an air-tight door operated by a lever from the driver's cab. A vacuum gauge is fitted in a suitable position. The central portion of the main tank forms the sludge tank, and has a floor slope of about 30 deg. towards the rear, where a substantial door is fitted, giving an opening area of 9 square feet. When closed the door is held in position by four clamps. The door is raised by means of a small hand winch and steel wire rope, allowing the refuse to discharge itself by the action of gravity. The clean water tank extends along each side of and under the front end of the sludge tank, providing an adequate supply of water for resealing the gullies after emptying. An independent chamber, separated from the clean water tank, is provided, into which liquid from the sludge tank can overflow through a perforated plate, and be run off as required into the main sewers. To the vacuum tank is attached the suction pipe of armoured hose, with a bore of 4½in. This pipe is supported by a jib crane, balance weights being provided to give easy handling. The suction valve is of a special quick-acting type, giving a full opening of 4½in., and a steel pipe of a length suitable for the gullies in any particular district is fitted to the underside of this valve. The capacity of the sludge tank is 705 gallons, and that of the resealing tank 850 gallons. The engine is of 35–55 horse-power.

THE NATIONAL GAS AND OIL ENGINE COMPANY, LTD.

There will be four oil engines on the stand of the National Gas and Oil Engine Company, Ltd., Ashton-under-Lyne, two of the vertical type and two horizontals. We illustrate the former in Figs. 19 and 20.

The single-cylinder engine shown in Fig. 19 is capable of developing 5 B.H.P. continuously for eight hours when running at 600 revolutions per minute, and is intended for working with practically any class of light fuel oil. The cylinder head is of a special chrome-alloy cast iron and includes a combustion chamber designed to give a maximum turbulence to the incoming charge. This, together with the thorough way in which the fuel is atomised, enables the engine to be started directly from cold without the assistance of preheating devices or compressed air. There is an exhaust valve lifter to ease the effort necessary to turn over the engine at starting. The valves are of the horizontal type, and can be removed without breaking any of the cylinder or pipe joints. Lubrication is effected on the splash principle, and requires about 1 pint of oil for every 40 hours of running. The fuel consumption at full load is 1 gallon per 3¾ hours. The weight of the engine without its fly-wheel is 4 cwt.

The larger vertical engine—see Fig. 20—is of the three-cylinder type, and is capable of developing from 22½ to 28 B.H.P. at speeds of from 800 to 1000 revolutions per minute. It can, however, be run at even higher speeds, with a corresponding increase of output, if it is equipped with special alloy pistons. The cylinders have renewable liners, and are of similar design to those of the smaller engine just described. The lubrication is of the forced feed type, and has an auto-cleaning strainer in the oil service. By rotating the inner member of this strainer, foreign matter is scraped off and falls into a sump, from which it can be easily removed. The fuel atomisers are of a self-cleaning type, and have no small holes liable to become clogged. The engine weighs 14½ cwt., and its cyclic variation is said to be 1 in 120.

Both the horizontal engines are of the single-cylinder type, with enclosed connecting-rods and splash lubrication. One of them will develop 26½ maximum brake horse-power when running at 320 revolutions per minute, and the other from 10 to 11 B.H.P. at 600 revolutions per minute. They have cylinders similar in general design to those of the vertical sets, but the smaller engine is equipped with a cartridge arrangement, so that it can be started in conditions of extreme cold.

(To be continued.)

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

ROAD ACCIDENTS.

SIR,—The leading article in the issue of October 27th on "Road Accidents" will, I believe, be regarded by many as somewhat inadequate to the urgency of the problem. It is said that time has not yet been given for the provisions of the Road Act to take full effect, or for those effects to be measurable, notwithstanding that the figures for the fatalities and injuries are still much the same as previous to the Act. In the four years ending 1932, no less than 26,659 have been killed and 707,371 injured on the roads. This fifth year will possibly bring the totals to 34,000, and a little short of a million respectively. Stupendous figures, utterly incredible twenty years ago.

Your readers are warned to avoid the risk of action which may prove too drastic. The 1930 Act sought to remedy a progressively evil state of affairs and was the result of some years cogitation. In five or more years of taking thought our statesmen have accomplished so little as to be indiscernible. I and others begin to fear that the matter may be taken out of their hands and a wave of ruthless indignation will suppress the intolerable nuisance which motor traffic has developed into.

When posterity reads in imperishable records of platinum and gold that we could only sigh and wring our hands before the monster which engineers had created, and whose appetite demanded the annual sacrifice of 6000 lives and the torture of some 200,000 more, they must surely brand our civilisation as the most futile and callous throughout the ages. It may be that they will be curious to learn what happened to the engineers; did they get away with it scot-free, or did they get what should have been coming to them?

It is an extraordinary fact that those who drive the deadly machines and the general public too, are still quite unaware of the magnitude of the slaughter, notwithstanding the amount of publicity given to it. I found this statement on a prolonged investigation made personally two years ago, and frequently checked since then. It is known in a general sense that a lot of people are killed and injured, but the highest guess out of more than 200 taken from people in all sorts and conditions of life has been 1200 killed, 9000 injured. The usual guesses were about 800 and 1700 respectively. The correct figures were given by two persons only, one an engineer.

I have been assured by one who is highly skilled in mathematics that the actual figures, though so immense and possibly because of their immensity, convey no specific impress to his imagination. This may explain why they have little or no effect upon the generality.

My investigations led to a very definite conclusion that excessive speed is the primary cause of the trouble. The limitations of a pedestrian's ability to observe, to estimate distance, and the impossibility of estimating the speed of an approaching vehicle are secondary causes which are nevertheless of primary importance, because they are limitations imposed by Nature and unchangeable.

A subconscious sense of superior force or invulnerability, combined with a hurrying and impatient optimism is the foundation of the desire for high speed. It is not a matter of necessity.

When I drive I find that I readily succumb to temptation and take chances which would be difficult to justify. But everybody keeps clear of a Scammell lorry, as a driver of one smilingly assured me, and all progress after the manner of Agag when passing a drove of cattle or a bunch of horses.

Engineers have put into the hands of the wholly and incorrigibly ignorant a machine every bit as dangerous as a loaded gun at full cock, and they have assured them that it can be controlled to a degree and in a manner which violate fundamental laws and are impossible.

Having raised this terrible demon, it seems to be up to engineers to provide its efficient control, and to inform Government in no uncertain voice that they can do so provided that a very small minority of the population are made to forego some of the pleasure and profit which has been acquired by an unfair and appallingly cruel exploitation of the generous tolerance of their fellow-countrymen. R. J. N. Willcox.

Wimborne, November 1st.

[We fear our correspondent has missed the real point of our article. It was that full details and statistics of accidents should be collected by some authority and be carefully analysed. When that had been done, we should be in a better position to formulate new legislation if it were called for. It is now understood that the Ministry of Transport is analysing the road accident returns.—Ed. The E.]

PREVENTABLE WASTE IN BUSINESS.

Sir,—A recent striking address on "Waste in Manufacture" directed attention to losses of a spectacular extent, losses which, to remedy, call for something like revolution. But what of the smaller leakages, unobserved because inconspicuous, yet throughout the year creating a very formidable total ? Here is a brief survey of small-looking, every-day things which may well repay consideration.

Commencing with administration and the board of directors, when a business expands and combinations are effected, there is an ever-present danger that directors get preoccupied with the general to the neglect of the particular. When that happens, decisions in their own firms may be delayed, or, worse, made hastily and followed by bad results, perhaps widespreading and lasting. Additional burdens cannot be taken on efficiently unless arrangements are made to keep the old duties well maintained.

Lack of financial budgeting for the approaching year may cause very serious loss, and, at times, consternation. Departmental budgets, although necessarily elastic, are a real protection against financial trouble. Indefinite responsibility gives rise to carelessness or indifference, with the natural consequences. On the contrary, when localised, and reasonable freedom is allowed, initiative is encouraged and efficiency increased. An inefficient or over-pressed department is sometimes answerable for a running loss, continuing until its reorganisation. This particularly affects the cost system, which, if inaccurate, inadequate, or dilatory, places the firm in constant danger.

In the offices—assuming them organised for the firm's requirements—there are possible leakages which, being cumulative, make up an objectionable total. Collection of statistics may be interesting, but are they all used ? It is not even enough that they are useful. All knowledge has potential value, but is only of real value when used. Then what a slack time the typists generally have in the earlier hours, a corrective being special duties or a dictating machine where circumstances—and the dictator—are suitable. Again, verbose and unnecessary correspondence. It has been said that no business letter costs less than a shilling. A large proportion of matters from some departments can be printed on post cards, or, if desired, in facsimile typing.

Small illnesses, colds and headaches, play their adverse part, and are often attributable to office conditions such as poor ventilation, bad lighting, and unclean telephones. It is not unreasonable, but certainly not general, for telephones to be disinfected every morning.

In still another direction are losses possible in unpunctual payment of monthly accounts, meaning discounts forfeited, credit impaired, and service from suppliers without enthusiasm.

It is, however, in the works that there are numberless rivulets which carry off money at an alarming rate unless constantly watched. Defective working conditions, bad lighting, poor heating, draughty shops, avoidable overtime, change or turnover of labour (it always costs something to train even a skilled man into a fresh job), excessive or insufficient machining allowance on details, want of precision in orders, verbal orders, lack of planning and of a monthly or weekly programme, absence of team work between dependent departments, inadequate internal transport facilities and different floor levels, power shortage, belting improperly attended to or used in too short drives, insufficient or inadequate tools for maintenance and outdoor staffs (whose wages and expenses are high and should be reduced by good labour-saving appliances), supplies not in stores when wanted, uncalled-for stock in stores representing dead money and probably quite usable if the right steps are taken about it.

Any of these things can, of course, happen occasionally in the most carefully managed works, but it is wise to see that they are not repeated often enough to become habitual. Robert True.

Bedford, November 6th.

COAL–OIL–GAS.

Sir,—In the controversy raging between the partizans of coal and oil, are we not "missing the wood for the trees" ? That our fleet and our fast liners must burn oil under their boilers is a question of expediency and is certainly not economical ; that sufficient oil for the fleet should be, if possible, synthetically prepared from home sources is, therefore, sound ; but that either hydrogenation or other process is warranted for the supply of a national and general purpose liquid fuel, its cost alone denies.

The importance of restoring our coal industry is, however, paramount, and if the report is true that Rotherham is hoping to put gas with a thermal value of 500 B.Th.U. on the market at 10d. per 1000 cubic feet, it means that gas power is available at practically the same cost as oil power, and gas is a direct and simple product from coal—in fact, it is the essence of coal power.

One understands, further, that the experiments in the use of compressed gas for road vehicles in place of petrol are proving highly successful, and, given a sufficient demand and the erection of gasworks at the pithead of collieries supplying suitable coals, and eventually a gas grid to feed important centres, it is probable that high-pressure gas could be sold after a period of development at a competitive figure with imported heavy oil, and far cheaper than synthetic oil, to the immense benefit of our coal industry.

Such gas would be suitable for road and rail traction, for short voyage aeroplane services, cross-Channel and coastal cargo and passenger ships fitted with gas engines, land drainage and water supplies, and for bringing the facilities of light, heat and power to outlying districts and villages not touched by the "grid," a storage shed for the containers and a weekly lorry service being all that would be required.

It is held that public works are not economically sound, though it is hard to understand this argument, where such works would save the dole and ensure the indigenous fuel resources of the country being efficiently developed. With our locked-up wealth and our millions needing work—in a nutshell, why not a National Gas Scheme ? It is our natural and modern form of indigenous power as surely as water power is that of Italy or Switzerland. And its full development would do much to put the country back to work and to restore our basic industries.

London, S.W.7, November 1st. S. P. Christie.

WATER LOWERING IN QUICKSANDS.

Sir,—Mr. Reed Cooper deserves thanks for drawing attention to the unwarranted claim of novelty made by foreign interests for a system of lowering underground water by pumping from a bore-hole. That this claim, so easily believed, apparently, by the Southern Railway authorities, should have been accepted as an adequate reason for the importation of foreign machinery is a matter difficult to understand.

Where there is so much professional knowledge idle at present, it seems a pity that civil engineers should not call in specialist opinion of British nationality when difficulties occur out of their experience. At least they would get disinterested advice and thus avoid any questioning of their desire to help home industries.

Waterworks Engineer.

November 7th.

The Little Salkeld Collision.

The incorrect performance of a simple duty—the turning of a block instrument switch from *through* to *open* at one movement instead of first to the midway position of *intermediate*—was the cause of the collision of July 10th at Little Salkeld, on the Settle and Carlisle section of the London, Midland and Scottish Railway. Many signal-boxes are closed at night or on Sunday, whilst others are open only when vehicles have to be attached or detached. Little Salkeld is one of the latter class, and, except under the conditions named, block communication is between Lazonby, 3 miles north of Little Salkeld and Langwathby, 1⅝ miles to its south. In order that vehicles may be attached to or detached from trains as may be required, the points in the main line have suitably to be moved, and that has, of course, to be done under the protection of the main line signals. Those signals stand at "clear" when the box is closed, and the interlocking compels them to be placed to the "danger" condition before the points are moved.

Porter-signalman Hannah at Little Salkeld went to his dinner at 12.30 noon and got back to the station at 12.55. At 1.8 a down freight train arrived which had a wagon of coal to detach, and to be placed in the siding on the up side. That necessitated setting back the engine and three wagons through the crossover-road from the down main to the up main line, previously to which the signals had to be put to "danger." Hannah should first have turned the switching-out instrument from *through* to *intermediate*, and had he done so his up line block instrument from Lazonby would have changed from *line blocked* to *train on line*, and he would have known that a train—the 12.44 express from Carlisle—was in the section. Instead of that, he moved the switch right over to *open*, put the signals to "danger," and opened the points. The driver of the freight train at once began to set back. Unfortunately, the express was so near that it had already passed the distant signal. That signal was 745 yards from the home signal, and its aspect was such as to intimate to the driver that he had a clear road through the station, and he approached at a speed of about 60 m.p.h., preparatory to climbing the 30 miles to Ais Gill summit, with a view of only 360 yards of the home signal. The results of the collision were less serious than might have been expected, as the only fatality was to the unfortunate driver of the freight train. The accident was inquired into by Lieut.-Colonel Mount, whose report was published on November 3rd. That document is dated August 18th, but its issue has, in accordance with the usual practice, been delayed until the criminal proceedings brought against the man were over ; otherwise, Colonel Mount's opinions might have been used in evidence against the man. Those opinions are that the man failed, in the first place, to telephone, in accordance with the regulations, to ascertain what trains, if any, were in the section. In the second place, he failed to notice the condition of his block instrument to Langwathby. On turning the switch at one operation to *open* his Lazonby instrument would at once go to *line blocked*, but, as the indications on block instruments can only be changed by the man in advance, that on his up line Langwathby instrument would not be affected, and it would continue to show *train on line*. Hannah's duty in that case, if, as he thought, the express had passed, would have been to wait until Langwathby had sent the train-out-of-section block signal. Such irregularities prompt inquiries as to the training of the man for his duties. In that relation mention must be made of the practice—introduced long before the war—of making a station-master responsible for more than one station. Little Salkeld, thus, came under the control of the man at Langwathby. It becomes increasingly necessary, therefore, Colonel Mount observes, to employ, particularly on main lines, only men of character who can be implicitly relied upon. Hannah was not really fitted for main line operation, and certainly proved that he was not competent to hold the position which he occupied.

In concluding his report, Colonel Mount says : "It speaks well for the extreme care which is generally exercised by signalmen, and the fact that this isolated failure, on the part of one man, who seems to have lost his head, has taken place, in no way suggests that there is any laxity or weakening in discipline with which the company cannot adequately deal." Equally gratifying is the earlier remark of the inspecting officer that he has no recommendations to make. That means that no changes in signalling are advised.

Another aspect of the accident must be noticed, particularly as it is of a complimentary character. We refer to the behaviour of rolling stock. The second coach on the express was an all-steel eight-wheeled bogie corridor third brake. Colonel Mount says of this vehicle that, although it was badly ripped on the off-side and its front end was thus crumpled, it clearly illustrated the strength of all-steel construction. Generally, it may be said that the stock throughout the train withstood the impact well, as all the six bogie vehicles, except the fifth—which was a London and North-Western composite—were fitted with shock-absorbing buffers.

Mandi Hydro-Electric Project.

A description of this project was given in The Engineer of Friday, March 3rd, 1933.

The possibility of the Uhl River, a tributary of the Bear, as a source of hydro-electric power, was first envisaged by Mr. J. W. Meares, C.I.E., some time Electric Adviser to the Government of India, and was later confirmed by Mr. R. N. Aylward in his hydro-electric survey of the Panjab. The bold vision of Sir Malcolm Hailey, Governor of the Panjab, brought the scheme within the region of practical possibility, and it remained for the energy and resourcefulness of Colonel Battye to carry this great project through.

It was Colonel Battye's unswerving faith and his indefatigable advocacy which helped to maintain the scheme in the days of carping criticism, when public feeling had been unnerved by the immensity of the venture and the cost of the undertaking.

Colonel Battye died, the result of a motor accident, at the verge of the fulfilment of his labours.

The project is the largest hydro-electric scheme undertaken by the Government of India. It is the first electrical system in India to transmit energy at 132,000 volts, the highest hitherto being 110,000 volts in the Tata scheme, and on the electrification of the Great Indian Peninsula Railway. It is also the first Government electricity undertaking in India to give supply direct to urban consumers.

The primary object of the Mandi hydro-electric scheme is to give effect to the desire of the Panjab Government to help the industrial development of the provinces by providing a plentiful supply of cheap power, over a wide area. The Panjab possesses no coal of commercial value, and coal has to be imported from Bengal. The scheme, when fully completed, will not only meet the needs of the industrial and urban consumers, but will supply rural areas, with particular reference to the development of agriculture.

The scheme includes a double circuit trunk transmission line operating at 132,000 volts from the power station at Jogendenagar to Lahore, 173 miles, and branch lines to important towns. In as many as thirteen towns, a complete system of local distribution is being provided, by which a direct retail supply will be given, which will eventually be extended to other towns.

A bulk supply to the Kapurthala State is under negotiation, and supply will eventually extend to the States of Faridkot, Malerkotla, and Nabha. Under terms of the agreement, a supply will be given to the Mandi State.

The supply of electricity will be eventually extended to rural areas for pumping water for irrigation in tracts outside canal influence ; for the relief of water-logged areas, and possibly for farming operations.

The supply for industries and agricultural purposes will be offered on a tariff that will vary inversely with the demand. The greater the consumption, the lower the rate.

For domestic purposes an "all-in tariff" is offered to encourage the use of electricity for all home uses, in addition to light and fans. That is a single set of wiring and one meter will only be necessary in each house.

The year ending on December 31st, 1933, is the period laid down by Parliament for the admission of architects to the Statutory Register created by the Act of 1931. It is already clear that the movement has been a great success. It has been an immense task to deal in so short a period with thousands of applications, every one of which had to be carefully scrutinised by an expert committee and approved by the Registration Council. The great majority of the members of the R.I.B.A. have already applied and the names on the Register are a striking indication of the way in which the leading men in the profession are supporting the movement.

Kinematic Design in Engineering.*

By Professor A. F. C. POLLARD.

PERHAPS the most fundamental and yet simplest of conceptions in engineering is that of the kinematic chain. It took shape in men's minds after much laboured thought and was first clearly enunciated by Reuleaux as the kinematic chain of mechanism with one link fixed, but later it was generalised by Koenig as an assembly of mutually coupled resistant bodies.

The kinematic chain therefore is to be regarded as composed of two distinct parts, the links and the couplings which connect the links together. The design of the links involves the greater part of machine design, and has received much attention, but the design of the couplings has in a sense been neglected, and it is my intention to discuss this side of design in the light of an important kinematical theorem.

A coupling between any two links will either fix the links or permit them to move relative to one another. In mechanism the majority of the couplings consist of the three simple and lower closed pairs: the turning pair, the sliding pair, and the screw pair, the latter being a generalised form from which the two former are derived. The elements of these lower pairs envelop one another, the brasses, for example, envelop the journal or the nut envelops the screw spindle, and these elements are integral with the connected links.

In this way the elements possess large mating or functional surfaces capable of resisting heavy pressures, and under certain circumstances they can be made air or steam-tight. In addition to resisting heavy pressures, an equally important consideration is that the enveloping elements can be designed to hold films of oil, thereby reducing the friction and wear to a minimum during relative motion.

Apart from the advantage of holding oil, however, the elements of a pair must have a certain small clearance between them in order that relative motion may be possible. This clearance cannot be reduced below certain practical limits if the elements are to move relative to one another without undue friction, since it is only possible to make surfaces within certain limits of perfection of geometrical form and to within certain limits of mating dimensions.

This imperfection of fit between the elements of the lower pairs introduces aberrations in the relative movement of the two links, and the relative motion of the first and last links of a chain will suffer from the algebraic sum of these aberrations. Although these aberrations are too small to matter for heavy-duty mechanisms, such as machines, whose function is to transmit power rather than geometrically exact motion, they introduce into light-duty mechanisms, such as scientific indicating instruments, serious imperfections of the instrument readings and other troubles which disturb their behaviour in an unsuspected manner.

A number of factors contribute to the imperfection of geometrical form during manufacture. In planing and turning operations, the spring of the tool and of the machine itself causes irregularities on the machined surface when the tool encounters a variation of surface hardness in the metal, and unless great care is taken the feed of the tool invariably produces extremely shallow grooves. These grooves can be very easily seen on an arbor which has been subjected to long use, and in some arbors a kind of spiral arrangement of surface irregularities is visible, which is due to a complicated state of vibration set up between the tool and work.

In grinding operations other irregularities make their appearance, and in plane as well as cylindrical works these take the form of a number of small flats, regularly arranged and mostly perpendicular to the travel of the wheel's surface. These flats sometimes produce remarkable patterns, and whatever may be the theory of their production, their regularity suggests vibration, produced in some way, as the cause.

All such irregularities of the surface can be reduced by lapping and polishing processes, but these processes will not eliminate and frequently enhance the production of pseudo-cylindrical and pseudo-spherical forms. In these the diameters are constant, but they depart from geometrically circular and spherical figures. This departure from true geometrical form cannot be detected by measurement between the parallel anvils of a measuring machine, which merely indicates the length of a diameter.

The manufacture of truly flat surfaces is not so difficult. The well-known method of producing fairly good flat surfaces was originally devised by Sir Joseph Whitworth, and consists in taking three surfaces and lapping them together in consecutive pairs. To produce flat surfaces which are optically perfect, however, requires special skill and is a costly process. To produce optically flat parallel surfaces is very much more difficult.

The truth of a plane lapped and polished surface can at once be checked by placing upon it a glass proof plane which is a true optical flat and which itself has been shown to be truly flat by checking against two other flats in consecutive pairing. When light falls upon the two opposed surfaces, interference bands are seen if the surfaces form a very small angle with one another, and any divergence of the metal surface from flatness is shown by a want of straightness and parallelism of the interference bands. In this way the actual divergence of a flat surface from an optical flat can be measured in terms of the wavelength of light. There is no such simple way of measuring the truth of circular form in cylinders or the spherical form in spheres, without the costly construction of special cylindrical or spherical proof plates in glass for each diameter manufactured. It requires elaborate interferometric arrangements to carry out such measurements for all diameters.

The most difficult surfaces of the lower pairs to produce are undoubtedly the helicoidal surfaces of screw threads. No systematic method has yet been developed which will produce an optically perfect screw spindle, and no method of checking the perfection of the helicoidal surfaces, which are ruled surfaces, similar to the methods used for cylinders and spheres, has yet been devised.

In instrument and other precision mechanisms the aberrations of the link motions due to these constructional imperfections of the couplings can be fully revealed by setting them in action slowly forwards and backwards over their complete range of movement.

For example, suppose that an indicating comparator, a voltmeter, or a weighing machine, is taken aperiodically in one direction through the range of its indications which are observed at intervals against the measured quantity, and the same operation is repeated in the opposite direction through the range of indications back to the initial value, great care being taken that the indicator never moves momentarily backwards. Then it will be found that if the indications are plotted against the measured quantity the two curves thus obtained will never coincide, but in general will form a loop, which is termed the hysteresis loop of the mechanism. The hysteresis loop, having force and displacement co-ordinates, has the characteristics of a work diagram and represents in fact a loss of energy which is localised at the couplings of the links or members constituting the kinematic chain of the instrument mechanism, and in the imperfect elastic deformation of spring members. Generally speaking, this energy is converted into heat and dissipated by radiation, and more often than is suspected, part of it may appear as electric potential.

Since the greater part of the variance in precision light-duty mechanisms is traceable to the clearances between the functional surfaces of the couplings, evidently the object of improved design is to eliminate these clearances. But, as previously indicated, on account of the increasing difficulties of manufacture as perfection of form in the functional surfaces is approached, there is a practical lower limit to the amount of clearance between functional surfaces which envelop one another.

We are therefore led to inquire how much of the enveloping surface of a coupling may be removed without interfering with its restraint upon the other element of the paired links. The restraint in all cases is equivalent to a system of forces acting in place of the enveloping surface upon the other element of the coupling, and this system of forces prevent all motions of the one link relative to the other except that particular motion permitted by the coupling.

Imagine one link fixed in space and the other not connected to it in any way but free to move in any manner. Let three mutually perpendicular axes x, y, z be drawn through any point of the fixed link. Then any motion whatever of the movable link may be resolved into a rotation about an axis and a translation about that axis much in the same way as a nut moves on a screw spindle, and this mode of constructing the displacement is called a "screw." This "screw" can now be resolved into three component translations parallel to the axes x, y, z, and three component rotations about them.

It is evident then that the movable link can have six different ways of moving relatively to the fixed link; that is to say, it has six degrees of freedom. We are thus led to the important kinematical theorem that "a rigid body has six degrees of freedom," and we shall see that the correct application of this theorem to the design of couplings presents remarkable advantages that can be gained in no other way, the most important of which, from the constructional point of view, being the entire elimination of manufacturing limits. To fix the moving link relative to the fixed link, these possible motions about the axes must be prevented by the system of forces properly applied between the elements of the links.

It must now be obvious that if the movable link makes contact with a surface of the fixed link at a point, say, with the surface $x=0$, a translation parallel to x is prevented and the movable link is robbed of one degree of freedom. It is easy to see that every additional and properly chosen constraint, produced by contact of a point of the movable link with a surface of the fixed link, will reduce the relative motion of the two links by one degree of freedom. It will thus require five constraints properly chosen to give the single degree of freedom of the lower pairs and six constraints to fix one link relative to the other.

A proposition of the greatest importance to the design of instrument mechanisms and, indeed, to the design of any mechanism whatever, immediately follows from the kinematical theorem. It is this: If the constraints between two members exceed six, the members will suffer unnecessary elastic deformation. For if the two members are relatively fixed by six constraints, it will require forcible contact or the most exacting workmanship at a given temperature to enable a seventh constraint to be introduced.

The application of this almost self-evident kinematical theorem to the design of couplings in instrument mechanisms was insisted upon by Kelvin and advocated by Clerk Maxwell. A number of beautifully simple examples are to be seen in Kelvin's instruments, but though he states that he was taught these principles by the eminent mechanician Professor Robert Willis, no earlier applications of the theorem of any importance are to be found. It is, indeed, strange that only within recent years has kinematical design found its way into instrument manufacture, and this advance is chiefly due to the insight of the late Sir Horace Darwin, M.I. Mech. E., who was head of the Cambridge Instrument Company.

Couplings with No Degrees of Freedom.[1]—These comprise "fixtures" or "clamps" in which it is intended that the two members shall be securely locked together without unnecessary elastic deformation. The commonest example may be found in the theodolite. In this instrument the levelling screws of the tribrach terminate in balls which rest on or are forced into contact with, by means of a locking plate, the six surfaces of three right-angled grooves cut in the base at 120 deg. with one another. Frequently, however, this design is misapplied and the feet fit cylindrical grooves which partly envelop the ball. By splitting the metal and drawing the two halves of the groove together with a clamping screw the ball feet can be held. To level the instrument the feet must be unclamped, and then the ball of each foot has only one indeterminate contact on the bottom of its mating groove. The instrument, in consequence, has at least, if not more than, three degrees of minute freedom; it has no definite position relative to the base, and the act of clamping the feet may throw it out of level. These inconveniences can only be minimised by careful fitting, and it is the chief characteristic of correct kinematical design that careful fitting is not required. The American system of using four levelling screws for theodolites is definitely wrong, kinematically and in practice. If the screws are tightened up too much it is possible to distort the main socket of the centres, and numbers of instruments are damaged in this way every year. The base of Casella's railway transit theodolite has Kelvin's hole, slot, and plane seatings for the spherically ended feet, and this arrangement of the surfaces in the coupling element has an important advantage over the three grooves spaced at 120 deg.

In the lower element of the Kelvin coupling a trihedral hollow is cut with three plane orthogonal surfaces. In line with the hollow a right-angled groove with two plane surfaces is formed. The sixth surface is the horizontal plane surface of the element. The three spherical surfaces of the mating element make contact with the surfaces of the hollow, the groove, and the plane respectively at different levels. The advantage of this form is that it is impossible to put any but the proper foot into the hole without detecting the mistake.

A trihedral hollow can be easily punched in the softer metals, but cannot be so formed in cast iron. It is a simpler matter to cut a conical recess, and this modification of the hollow is frequently used. But the use of a conical hole may lead to a possible violation of the kinematical principle.

The possibility of designing a coupling so that two members may be relatively fixed without undue elastic deformation should appeal to engineers, and it is interesting to note that the practice of fixing the engine and gear-box unit, in motor car construction, to the unavoidably flexible chassis by three or four points of support is increasing. In some well-known makes of car the engine is mounted at one point on either side in front and the third point is situated at the rear of the gear-box casing. The significant point about these methods of supporting the engine unit is that motor car engineers are realising that the old method of bolting the engine unit to the frame at any number of points is unsatisfactory. The unevenness of the road causes variable elastic deformation of the frame, and it is bad practice to mount the engine unit so that it tends to resist the frame shifts. Moreover, though the design of the engine aims at as perfect a balance of reciprocating parts as possible, the design of the mountings strives to secure smooth running by permitting the engine unit to rock slightly relative to the frame, in a controlled manner.

Couplings with One Degree of Freedom: (1) *Trans-*

---

* The Institution of Mechanical Engineers; the twentieth Thomas Hawksley Lecture.—Abstract.

[1] Under this and each subsequent similar heading Professor Pollard described and illustrated specific examples, drawn from practice, of the types of coupling mentioned.—Ed. The E.

lational Couplings or Slides.—The manufacture of precision dovetail slides or, indeed, any other form such as tongue slides, is notoriously costly, since not only must the limits on the elementary functional surfaces be checked by limit gauges during manufacture, but the possible want of parallelism of the surfaces which may develop during manufacture must be checked by functional gauges. Moreover, in the design of the usual heavy engineering slide, it is difficult to generate planes of precision without constructing the female member of several pieces. These pieces have to be assembled by screws, the tightening of which may very easily distort the plane surfaces.

As the clearances are diminished the friction is increased, which completely upsets the performance of some delicate mechanisms. The friction, for example, in the fine adjustment slide of microscopes introduces marked variance into the micrometrical movement. To overcome these imperfections in the fine adjustment mechanism of their microscopes, Messrs. Leitz have introduced a kinematic ball-bearing slide with very satisfactory results. One of the simplest forms of kinematical slide is a cylinder sliding on the four surfaces of two "V's" with an arm integral with the cylinder ending in a point which makes contact with a plane parallel to the axis of the cylinder. This latter constraint prevents rotation of the cylinder upon its V supports; if the plane is inclined to the axis of the cylinder the motion will not be a translation, but a screw. The geometrical perfection of the motion, therefore, will depend upon the correct setting of this plane, its truth as to flatness, and the geometrical perfection of the cylinder. It is a simpler matter to fulfil these conditions than to make an equally perfect sliding pair with enveloping surfaces. In kinematical couplings the geometrical perfection of the relative motions depends only upon the perfection of the geometrical forms of the guiding surface, and not upon their dimensions or closeness of fit with other surfaces, and this is an advantage of the greatest importance to economic manufacture.

In mechanisms which require the sliding friction to be a minimum, the five necessary constraints can be replaced by rolling balls, and the first design of this kind was made by Mr. William Taylor in 1915, when he devised a screw gauge measuring machine for the Screw Gauge Department of the Ministry of Munitions. The micrometer holder slides kinematically on an intermediate member—the carriage—which also slides kinematically on the frame, the two slides being at right angles to one another and similar in design. In the cast iron frame two right-angled parallel grooves are cut, and in the carriage there is a similar groove and a flat at the bottom of a groove. Two balls rest in one groove in the frame and a third ball in the other. When the carriage is placed on these, the two balls make contact with the two surfaces of the V-groove and the third ball with the flat. So the carriage has four contacts with the two balls and one with the third ball, constituting the five necessary constraints, and is therefore restrained to move parallel to the two opposed grooves, whereas the flat permits the ball in its opposing groove to take up a position of repose.

In measuring machines requiring greater accuracy, the plane surfaces of the grooves may be replaced by the surfaces of accurately ground hardened cylinders suitably supported, so as not to bend under load and placed side by side in pairs, so that the tangent planes at the points of contact with the balls form an angle of 90 deg. Such a design of a ball-bearing slide is well shown in the universal gauge measuring machine made by Messrs. A. C. Wickman, of Coventry.

The strict application of the kinematical theorem to the design of the ball-bearing slide permits the use of three balls only, two in the groove giving four constraints, and one on the flat giving the fifth. If the number of balls is increased, then the theorem is violated, and, as in the fit of functional surfaces, precise workmanship becomes necessary and the sizes of the balls must be the same within very small limits. Otherwise, as in the construction of ball bearings, only those balls required by the theorem will take the load and the others might as well be absent.

When the moving member has to travel long distances along the slideways, balls are inconvenient, since they travel with less speed than the moving member, and may become sufficiently displaced in a long run to cause instability of the moving member. In such cases the ball constraints may very conveniently be replaced by rotary ball bearings fitted to the moving member. When ordinary rotary ball bearings are used in this way they must be carefully fitted if their outside cylindrical surfaces are to make line contact with the plane surface of the ways. But such practice is contrary to the principles of kinematic design, one of the chief characteristics of which is that functional fitting between the elements of the couplings is not necessary. The conditions of the theorem, however, can be satisfied and all exact fittings of the rollers eliminated by grinding the outside cylindrical surface of the ball bearings to a spherical form of large radius, or, if line contact is desired, by using bearings, which, having ball races of spherical form, will make line contact automatically.

(2) *Rotary Couplings.*—In certain optical instruments the accuracy of their readings depends upon the accuracy with which a member rotates with reference to a divided circle. If the axis of rotation of the member, which carries an indicator, such as a vernier, does not exactly coincide with the centre of the divided circle, errors of excentricity are introduced into the readings. Though such errors of excentricity can be eliminated by taking the mean readings at the two ends of a diameter, this cannot be done when the divided scale is not a whole circle, such as in sextants. In such instruments the greatest care must be taken in constructing the axes.

These axes are generally constructed as complete journals which are liable to introduce indeterminate errors of reading, apart from excentricity errors, due to the necessary clearances between the functional surfaces. In theodolites, for example, the greatest care is taken to reduce these clearances to a minimum and yet at the same time permit smooth movement, by constructing the axes as slightly tapered cones with end restraint. Though many manufacturers lap the two components of these axes together, this cannot be done with precision, since a conical surface has variable curvature along its length. Apart from the danger of producing rings on the lapped surfaces, there is the greater danger of driving the abrasive into the surfaces, which will subsequently damage the bearing during use. A simple manner in which these objections and constructional difficulties may be met is suggested by the design of a rotary coupling for the grating table of a 21ft. grating spectrograph at present being designed and constructed at the Imperial College of Science and Technology, South Kensington. A shallow steel cylinder of large diameter is lapped on its upper surface, the central portion being removed by recessing, into a precision plane and its cylindrical surface is ground and lapped to as true a cylinder as possible, its exact diameter being of no consequence. The grating table is coupled to this cylinder by three plugs of gun-metal 120 deg. apart fitted to the table with a gentle force fit and making contact with the plane surface of the cylinder, whilst two plugs tapped with a fine thread into the table are in contact with the cylindrical surface of the cylinder, also at 120 deg. apart. On the opposite side of these two plugs and bisecting the angle between them, a spring-controlled plug is fitted with an easy sliding fit to the table. The spring is sufficiently powerful always to maintain contact between the constraints provided by the two plugs and the cylindrical surface of the cylinder. The necessary clearance in the sliding fit of the spring-controlled plug cannot be detrimental to the precise movement of the coupling, since the only function of this plug is that of force closure. Contact at the three constraints on the plane surface of the cylinder is secured by the pull of a central screw acting on a spring washer and thrust ball bearing.

As with slides, the sliding constraints in rotary couplings can be replaced with steel balls in order to reduce the friction. The ordinary ball bearing in which the balls make contact with grooves, the radius of which is a little greater than that of the balls, is a coupling of four degrees of freedom. Kinematically, the function of the bearing is not changed in any way if all the balls are removed except three set 120 deg. apart. Two of these act as the kinematic constraints, whilst the third introduces the necessary pressure to maintain these constraints. So the bearing is equivalent to a coupling with two constraints. Each ball makes contact at one point in the grooves, but on account of the depth of the grooves the possible rotations about axes perpendicular to the axis of their common plane are very small and the end movement is very slight, but nevertheless it is not strictly constrained. These three slight degrees of freedom together with the intended rotation make up the four degrees of freedom. In order, therefore, to ensure that an axle shall have strictly one degree of rotation it is necessary to mount it in two ball bearings and to prevent the minute end-play with a thrust bearing.

(3) *Screw Couplings.*—The degree of freedom to perform screw motion is of the most general character, for it consists of motion parallel to an axis compounded with a rotation about the axis in fixed proportion to the axial translation, leaving every other motion free. The helicoidal surfaces of practice form the screw thread which is generally complicated by the unnecessary contact of root and crest radii. The helicoidal surface is the most difficult elementary surface in mechanism to generate, and the screw couplings of instruments should be stripped of unnecessary complications which, however, may be necessary in heavy engineering to transmit heavy loads or pressures. The construction of the precision screw coupling should be concentrated upon the production of precision helicoidal surfaces only, and the radii of crest and root should clear. In practice the five constraints for screw spindles with V threads can best be secured by the functional contact of four suitably located portions of the fixed nut.

The seating of a screw spindle designed in this manner, which was first pointed out by R. S. Whipple, is constructed by casting white metal around the accurate screw spindle and then splitting it in half. The lower portion fixed to the framework of the instrument has the thread cleared away except at four parts, corresponding to the four constraining surfaces of a rotary coupling. The upper half of the seating has the thread cleared away except at the two top central areas directly opposite the two lower portions. When the two halves of the seating are pressed together with the screw spindle between them, the four lower portions of the female thread in contact constrain the spindle with a pressure which may be varied within wide limits. Screws formed in this way have practically no clearance and suffer from practically no backlash.[2]

* * * * * *

It must now be abundantly clear that the outstanding advantages of kinematic design are that:—

(1) It reduces elastic strains in the coupled links to a minimum.

(2) It eliminates many of the troublesome and costly limits on functional surfaces which would otherwise be necessary, and substitutes guiding surfaces of precision in relation to form, but not in relation to size.

(3) Adjustments are readily provided, both for functional operation and wear.

(4) Localisation of the forces facilitates design for exacting conditions of equilibrium.

The only serious objection to kinematic design is that, if rigidly applied, the load at any constraint, taking the form of a spherical surface in contact with a plane, cannot be permitted to take too high a value. Surprisingly high values of the load do not, however, appear to damage the surfaces if they are sufficiently hard and polished. In an appended note[3] a *résumé* of Hertz's theory of localised contact between deformable bodies has been sketched, and it is there seen how the safe load depends upon the elastic constants of the materials used as well as upon the maximum stress p at the centre of the area of elastic contact. The magnitude of p may safely reach values far in excess of the limit of proportionality, but at present we are ignorant of these values for the various materials of construction. This stress falls off rapidly as the boundaries of the pressure area are approached, as well as towards the interior of the solids in contact. It is therefore confined more or less to the skin of the solids making contact, and in order that the safe loading may be increased, possibly the most effective method of hardening steel constraints is by nitriding or by Edward G. Herbert's "Cloudburst" method. There can be no doubt that hardness as measured by Brinell's method is the kind of hardness which greatly influences the safe loading, so that although steel balls suitably fixed to a component form ideal points of contact, the safe loading may be increased by forming the contacts on small accessory parts, such as plugs, force-fitted to the components, and constructed of such hard materials as the cutting alloys "Ardoloy," "Cutanit," or "Wimet." As science progresses with further refinements in measurement, it is conceivable that instruments of the highest precision in the future will have the kinematic constraints constructed of such highly polished hard materials and even of sapphire or diamond.

An objection to the use of steel constraints is that relative movement in the absence of moisture causes corrosion and deposition of rust. This remarkable phenomenon, which takes place even when one of the contacts is sapphire, has been described by Tomlinson.[4] Such deposition of rust seriously interfered with the running of the ingenious friction variable-speed mechanism of Kennok Gears until it was discovered that the difficulty could be entirely overcome by lubricating the ball contacts with oil mixed with 50 per cent. of zinc oxide.[5] A film of metallic zinc of molecular thickness forms on the steel surfaces and not only prevents the corrosion, but is too thin to interfere with the manufacturing limits.

The advantages of kinematic design weigh heavily in favour of its consideration in relation to heavy-duty mechanisms and structures such as the clamps used in tubular steel scaffolding. Since the constraints are definitely located, the system of forces acting on the coupling can be calculated and the "point contacts" can be expanded into functional surfaces sufficiently extended to take the loads safely. Such procedure, however, violates the principle and careful fitting becomes necessary at the constraints, but the advantage gained in these cases is that no more constraints are designed than are necessary. The forces are definitely localised, and unnecessary strains are minimised.

Lubricated surfaces moving with relatively high velocities present an entirely different problem. The oil in such couplings is the source of hydro-dynamical pressures set up by the motion, and the present designs cannot be interfered with. They may, however, be improved in many cases as instanced by Professor J. E. Sweet, in his fascinating little book[6] entitled "Things That are Usually Wrong."

THE Southern Railway Company's station at Tonbridge is to be enlarged and improved at a cost of £95,000. The junction between the Redhill and Sevenoaks lines is to be rearranged so as to increase the speed limit of 30 m.p.h. to 40 m.p.h.

---

[2] The lecturer then proceeded to consider couplings with two, three, four, and five degrees of freedom and compound couplings.—ED. THE E.

The Institution of Civil Engineers.

At the opening meeting of the session on November 7th, 1933, the President, Sir Henry Percy Maybury, delivered an address to the members, of which the following is an abstract.

After expressing his appreciation of the honour which the members of the Institution had conferred upon him, the President said he proposed to take for the subject of his address phases and aspects of engineering associated with local and central government administration, in which the greater part of his life had been spent.

Upwards of forty years ago he received his first chief appointment in the local government service, and in 1913 he entered the Government service, from which he retired in 1928. He was sure it would be conceded that he had thus lived through a period of unparalleled improvement and vast changes in local and central government administration.

Prior to the date of his first appointment, county and local engineers and surveyors were often part-time officers only, but after the constitution of County Councils, and Rural and Urban District Councils, full-time officers were appointed to supervise all engineering services connected with public health, and often those of gas, water, public lighting, and highways.

After referring to the passing of the Locomotives on Highways Act, 1896, which, by permitting a speed of 12 miles an hour upon the highways, gave great impetus to the construction of the motor car, the President drew attention to the great strain which such vehicles placed upon the roads, which had never been designed or constructed to support such traffic, and which had received little or no attention since the commencement of the railway era, local authorities being seriously embarrassed by the necessity for considerable extra expenditure upon maintenance.

The motor car was becoming increasingly popular, and as a result of insistent demands, the Motor Car Act, 1903, was passed, which allowed increased speed and greater freedom to the motor vehicle, but gave no relief to highway authorities and their officers.

Eventually, in 1909, a horse-power tax was imposed upon pleasure motor vehicles and a duty upon petrol. Under the Development and Road Improvement Funds Act, 1909, the Road Board was established, primarily to receive the moneys derived from this taxation, and to allocate them to local authorities for road improvement works. It soon became obvious, however, that direct State assistance could not be confined to improvement works alone, and, in 1913, a scheme providing for the payment of grants towards the maintenance of certain classified roads was recommended by a Departmental Committee. The work of classifying the roads was put in hand, and was well advanced when war broke out in 1914.

After describing the road work carried out in France by an organisation composed principally of men drawn from the road service in this country, the President referred to the great arrears of maintenance which at the cessation of hostilities had accumulated in connection with all means of transport at home, and to the establishment in 1919 of a Ministry of Transport, under whose control all forms of transport were brought. The President was appointed Director-General of Roads in that Ministry, and held that position until his retirement from the service nine years later.

The classification of roads scheme was resumed and completed, and in 1920 the passing of the Roads Act made it possible for contributions from the Exchequer to be made to local authorities towards the cost of the maintenance and minor improvement of the roads so classified, further sums being made available for necessary road and bridge construction and for major improvements. Under the provisions of the Local Government Act, 1929, the original scheme was revised, but contributions were still made to local authorities in respect of the 42,995 miles of classified roads, representing 24·3 per cent. of the total road mileage of the country. The President then explained the organisation set up for dealing with roads under the Ministry of Transport, and referred to the power of the Minister to pay half the salary and establishment expenses of the Engineer and Surveyor in charge of highways.

After giving particulars of the road works which, soon after demobilisation, were put in hand in and around London to relieve unemployment, he referred to the many road and bridge works which had been carried out all over the country since the war, and, in connection with the construction of the Mersey Tunnel, said he was sure that all members present would desire to express their sympathy with Sir Basil Mott (whose name would always be associated with that great work), and to wish him a speedy recovery.

The President then referred to the debt of gratitude which the nation owed to the civil engineering profession for splendid services in carrying out the vast programme of new roads, and said it was unfortunate that such great engineering works should be the subject of controversy. The works described, however, were instrumental in providing a large amount of employment, during a difficult industrial period, and much of what had been done was bound to prove of inestimable value to the community as a whole. The great improvement of roads during post-war years would be reflected in reduced costs hereafter.

He expressed the opinion that engineers employed on highways need not be apprehensive that their duties would suffer diminution, and referred to the necessity for devising means for reducing the alarming number of accidents on the highways of the country. That problem should receive quite specialised attention, and he suggested that chief engineers should seriously consider the advisability of including in their organisations traffic branches, whose sole function should be the study of this grave problem. He also referred to the work of the Traffic Signs Committee, which reported in May last, but feared that when everything humanly possible had been done, there would always be a large number of inefficient and careless drivers, whose incapacity and want of thought would endanger the lives of others.

In connection with the development of the love of travel in post-war years, he said that whilst each person in Greater London travelled on an average 283 times on one or other of the rail and road services in 1912, in 1932 the number of journeys per person had risen to 482, and it was only to be expected that this love of movement would continue.

He drew attention to the development of air transport, to the grouping of the railways under the provisions of the Railways Act, 1921, to the great work carried out by the Electricity Commission and the Central Electricity Board, and referred to the great problem of London traffic, and the establishment of the London Passenger Transport Board under the provisions of the London Passenger Transport Act of the present year.

Travel over the highways having long since lost all local colour, the President wondered how long it would be before the control and management of the highways outside big centres of population would be entrusted to some public board or authority.

He referred to the necessity for taking a wide view in dealing with transportation matters, and for providing for the adequate lay-out of highways on sound transport lines in all regional town planning schemes.

In dealing with local government he had, not unnaturally, given prominence to engineering related to highways and bridges, and the traffic thereon, but he had by no means forgotten the other great and important engineering works entrusted to local authorities, many of which he enumerated.

He stated that there were on the roll of the Institution nearly 11,000 members resident in all parts of the world, and drew attention to the increasing number of municipal and county engineers in that membership.

The outlook for civil engineers (he continued) is somewhat depressing, and it is a source of grief to the older members that so many of the younger professional men should be out of employment; but there is clearly an improvement manifesting itself. Our basic industries have at last made a move forward, resulting in increased employment for our workpeople, whilst the traffics recorded weekly on our transport services show gratifying increases. The figures which have been made available to us in the national revenue returns are also very encouraging, and although it may take some time to reach the end of the depression, be sure the tide is coming in.

A hundred years ago, under not dissimilar world conditions, that great essayist, Lord Macaulay, wrote :—" History is full of the signs of the natural progress of society. We see in almost every part of the annals of mankind how the industry of individuals, struggling up against wars, taxes, famines, conflagrations, mischievous prohibitions and more mischievous protections, creates faster than governments can squander, and repairs whatever invaders can destroy. . . . The present moment is one of great distress. But how small will that distress appear when we think over the history of the last forty years —a war, compared with which all other wars sink into insignificance—taxation, such as the most heavily taxed people of former times could not have conceived; a debt larger than all the public debts that ever existed in the world added together; the food of the people studiously rendered dear; the currency imprudently debased, and imprudently restored. Yet is the country poorer than in 1790? We firmly believe that, in spite of all the misgovernment of her rulers she has been almost constantly becoming richer and richer. Now and then there has been a stoppage, now and then a short retrogression; but as to the general tendency there can be no doubt. A single breaker may recede; but the tide is evidently coming in. . . . On what principle is it, that when we see nothing but improvement behind us, we are to expect nothing but deterioration before us?"

That history will repeat itself, and that, once again, members of the civil engineering profession will be fully employed I have little doubt. There are, however, a few home truths which I would like to submit before closing my address. I would like to ask this question: How many of our younger members are fitting themselves for the great responsibilities to which they should eventually succeed? I was reading the other day that most charming and instructive address which was given to this Institution by our great and revered leader, Sir Benjamin Baker, in 1895. Dealing with the education of engineers at that time, he said :—" If anything more remains to be said on the subject, it must therefore be of the nature of a warning, that technical education is of little value unless accompanied by the practical experience, sound judgment, and bold initiative which, rather than book knowledge, characterised the famous members of this Institution in the past. Education will do much, but it will not endow a man with common sense, nor will it make his opinion on a multitude of important subjects worth more than that of a naturally observant person." Later, Sir Benjamin said :—" . . . blind acceptance of authoritative statements in books, without due regard to the sufficiency of the data upon which those statements were founded, obviously warped their judgment. There are not wanting contractors and manufacturers who contend that some of the highly trained young engineers of the present day are not wholly free from faults of the latter kind. It may be well, therefore, for all engineers to remember that most of their elaborate calculations involve some assumption which is more convenient than true."

Those words, delivered from this chair thirty-eight years ago, are very largely applicable to present-day conditions, and I would commend to all, old and young, the very sound advice which was tendered by one who was not only eminent in his profession, but a great leader of men.

SIXTY YEARS AGO.

Of the two leading articles in our issue of November 14th, 1873, one was devoted to the fate which had overtaken Inigo Jones' water gate at the foot of Buckingham-street, near Charing Cross. The other, by way of contrast, discussed railway construction in Ashantee. The construction of the Thames Embankment had left the water gate, the last remaining vestige of old York House, far inland from the margin of the river. It stood, and still stands to-day, on the Strand side of the gardens which the Metropolitan Board of Works—the forerunner of the London County Council—laid out on the reclaimed land between the old and the new river line. We were grieved at the fact that the level of the garden ground was higher than that of the water gate, and that it had been found necessary to raise the ground round the old structure, until it appeared to be sinking like a stage ghost through a trap door. Some question of divided ownership apparently prevented the Board from dismantling the structure and re-erecting it on a higher level. To-day the old gate, an object of much interest to London visitors, still stands in the pit created for it when the Embankment Gardens were planned. . . . With railways in Ashantee we were concerned because of the approaching campaign under Sir Garnet Wolsely, for which the final preparations were then being made. On a previous occasion we had criticised the choice of artillery material which Sir Garnet had made for the expedition. Now we took exception to his plan, under which 10,000 tons of railway material were to be shipped to Africa to facilitate the progress of our forces from Cape Coast Castle to Coomassie. We maintained that the country was not suitable for the construction of a railway, and that if one were built it would cost more lives to defend than it would save. Appealing to history, we turned back to the times of Napier and Havelock, even to those of Wellington, and showed that in India and in the Peninsula they had relied on the primitive means of transport provided by the country rather than upon more highly developed systems which they might have imported. We were not blind to the use which the Germans had made of the railways in the Franco-Prussian War, nor to the inestimable services which the railway constructed by us in the Crimea had rendered. But in Ashantee, so we argued, the latest developments of mechanical science would be out of place and might well prove an embarrassing over-refinement which would seriously affect the success of the campaign. That fate, before now, had, we urged, befallen more than one highly disciplined force in the face of a savage or inferior foe. The history of the campaign, as we now know it, seems to justify our criticism of the mechanical equipment prepared for it.

The annual census of motor traffic taken by the Automobile Association at more than 100 spots in England, Wales, and Scotland, during a week in September, shows that there was an increase of 42 per cent. as compared with 1932. Private cars increased by 19 per cent., heavy motors by 12 per cent., and motor cycles by 12 per cent. As compared with the corresponding week of 1928, the increases were 49 per cent. for private cars and 63 per cent. for heavy motors. There was a decrease of 8 per cent. in motor cycles. The census of this year included 3,252,050 vehicles.

A new photo flash lamp that gives more light for its size than any source in existence to-day, and designed especially for amateur use, where it is expected to open new picture-taking possibilities, has been developed by the Incandescent Lamp Department of General Electric Company, of New York, at Nela Park, Cleveland. The bulb of the new lamp contains a quantity of extremely fine aluminium foil crumpled around a 1·5-volt filament. The remainder of the bulb interior is filled with pure oxygen, and it is the rapid oxidation of the foil which causes the tremendous light output. One lamp is usually sufficient for photographing subjects up to a distance of 12ft. with any type of camera when fast amateur film is used. The noiseless, smokeless flash emitted occupies one-fiftieth of a second.

Railway and Road Matters.

The report by Lieut.-Colonel Mount on the fatal collision of July 10th at Little Salkeld was issued on November 3rd. A summary is printed on another page of this issue.

Modernisation schemes which include the provision of large mechanical coaling plants are to be carried out by the L.M.S. Railway Company at the locomotive running depôts at Ashton (Birmingham) and Rugby.

The L.M.S. Railway Company has decided to exhibit the full name of Llanfair Station. It is Llanfairpwllgwyngyllgogercychwyrndroblllllandysiliogogogoch, and signifies "the Church of St. Mary in a hollow of white hazel near to a rapid whirlpool and to St. Tysilio's Church, near to a red cave."

There is now under construction in Germany a 4-4-4 oil locomotive of 1000 B.H.P., which is fitted with direct drive—only the third example of this principle in twenty years. It is powered by a four-stroke engine, and will thus be somewhat more flexible than the previous direct-drive locomotives, which had two-stroke engines.

The new station of the L.M.S. at Leigh-on-Sea, with a large goods yard adjacent, is situated a short distance to the west of the present station, which is inadequate for the growing traffic and will be closed as soon as the new one is opened on January 1st. Another new station at Chalkwell, on the Southend side of Leigh-on-Sea, was recently opened, thus providing the district with two stations instead of one.

The Ministry of Transport railway statistics for July show that, when compared with the corresponding month of 1932, there was an increase of 2·8 per cent. in the number of passenger journeys, but a decrease of 7·0 per cent. in the receipts from passengers. The tonnage of freight carried increased by 2·0 per cent., and the freight traffic receipts by 1·4 per cent. Freight train-miles rose by 1·8 per cent.; the average train load from 114¼ tons to 116; and the net ton-miles per engine-hour from 430¼ to 439¼.

The opening of the new service between Cockfosters and Uxbridge has led to the London correspondent of a North-country paper giving a few interesting items on the electrification of the Underground. Therein it was observed that steam-worked goods trains can still occasionally be seen on their way to Smithfield Market. Those, we would remark, are those of the Great Western Company. Additionally, there may be added the Midland—now the L.M.S.—coal trains from the North and South-Western Junction Railway at Acton, through Hammersmith and Earls' Court to West Kensington and back.

Work has been started in Germany on the construction of three Transcontinental motor roads in combination with the railway system which, like the Italian motor roads, will be reserved for motor traffic only. They will total 6500 kiloms. in length. The tonnage of constructional steel required will amount to over 200,000 tons, and the building of the roads is to extend over twelve years. The Government is to guarantee the interest on the money spent, but the scheme will receive the financial support of the banks, the motor industry, the steel and heavy machine industries, and foreign capitalists. One of the most important roads will be that from Lübeck-Hamburg to Frankfort and Basle, in Switzerland.

A very interesting railway case was recently before the Court of Appeal, which implies that the farmer must share with the dairy companies and the railway companies the economies that result from the bulk conveyance of milk. The contract between the farmer and the dairy company provided that the former was to be paid a specified amount "less a sum equal to the railway carriage of the milk to London." As a result of the milk being conveyed in 3000-gallon tank wagons, the railway gave the dairy company a rebate of 30 per cent., and the judgment of the lower court, now confirmed by the Court of Appeal, was that the defendants were not entitled to deduct a sum in excess of that actually paid.

In view of the retirement on December 31st next of Mr. A. C. Stamer, assistant chief mechanical engineer, London and North-Eastern Railway, there are to be a southern area and a north-eastern area mechanical engineer. Mr. R. A. Thom, now mechanical engineer, Doncaster, takes the former position, and Mr. E. Thompson, mechanical engineer, Stratford, takes the north-eastern area. Mr. A. H. Peppercorn, carriage and wagon works manager, York, becomes assistant mechanical engineer, Stratford; Mr. W. H. Brown, carriage and wagon works manager, Doncaster, succeeds Mr. Peppercorn; and Mr. D. R. Edge, carriage and wagon works manager, Dukinfield, goes to Doncaster to follow Mr. Brown.

At a luncheon at Olympia on November 2nd, in connection with the Commercial Motor Transport Exhibition, Mr. Oliver Stanley, the Minister of Transport, spoke of his hopes of the Traffic Advisory Council, which is to be set up under the Road and Rail Traffic Bill. He said that it would be "a tremendous advantage if they could get some system that would give a fair chance to all the varying forms of transport. If, as a result of the Traffic Advisory Council, they could come to some arrangement with all the branches of the transport industry, it would be to the advantage not only of the country, but of the industry itself. It would be worth their while to make this Council a live body, and that depended on the people whom they put on it and the support they gave them."

The announcement made herein on August 11th as to a co-ordination between the four grouped companies and the cartage firms of Carter, Paterson and Co. and Pickfords, may now be followed by the intimation that the railways have purchased, as from October 31st, in equal proportions, the whole of the ordinary capital in the cartage companies, and the boards of the latter have been re-arranged to suit. As we have seen this described as a purchase of rival interests, we would say that that is hardly so, except in the London area; most of the traffic collected by the cartage firms eventually found its way on to the railway. A direction to which we would like to see the railway companies turn their attention is the hundreds of thousands of pounds they pay out yearly in what is termed in the Railway Returns as Passenger Ticket Agents' Commission. That amount last year was £240,340, but in such a normal year as 1928 it was £325,408.

Notes and Memoranda.

It is only within the last few years, says a report on the Influence of Temperature upon the Strength Development of Concrete, recently issued by the D.S.I.R. (Building Research), that it has been realised that the expansion due to heat hydration of the cement, followed by contraction on subsequent cooling, has been largely responsible for the detrimental cracks that have been observed in large concrete masses.

It is reported that Professor Swaardemaker has constructed an absolutely non-resonant studio in Utrecht. Between each of the walls a complete vacuum has been achieved. Each wall has a composition of paper, wood, cork, seaweed, human hair, and a special sort of stone, and the internal wall is hung with a "variety of tissues." It is not stated whether the studio is intended for broadcasting or as a refuge from it.

Writing in *Cheap Steam*, the house journal of Ed. Bennis and Co., Mr. E. Ingham says that experience shows that when a change is made from oil-firing back to coal firing, there is a certain amount of risk of flue explosions when the boilers are started up again. If the oil-firing has not been efficient, partially consumed oil may have settled on the inside surfaces of the flues, and given off vapour, which, mixing with air in the right proportions, will form an explosive mixture. When the boilers are started up, sparks from the furnaces may then ignite the mixture. It will be realised that to enter the flues of an idle oil-fired boiler with a naked light is a somewhat risky proceeding; the flues should always be ventilated first.

The national grid, the problem of distribution, and the development of sales formed the subject of Mr. G. G. L. Preece's inaugural address as Chairman of the North-Western Centre of the Institution of Electrical Engineers on October 24th at Manchester. The "grid," he said, was based on estimates of consumption that proved to be unduly optimistic, but who could have foreseen the great trade depression? The Central Electricity Board was undoubtedly anxious and recognised that great efforts must be made to ensure the grid being a financial as well as a technical success. Hence the reorganisation of the E.D.A. and the proposed reorganisation of distribution. The one guiding principle should be trusteeship, and the time was not far distant when the running of electricity undertakings for any other purpose than the benefit of the consumers would not be tolerated. National public control would come eventually, if not immediately.

In addition to their use for high-speed cutting, the tungsten-carbide alloys find numerous applications where their resistance to wear is of value. Thus, in one plant having a large number of hydraulic presses, ranging in capacity from 25 to 2000 tons, four men, says *Machinery*, were formerly kept busy replacing worn stems and seats. Since this concern adopted the practice of tipping the stems and seats with tungsten carbide, the part-time service of one man only is required for this work. The work blades of centreless grinders are subject to such severe wear in many operations that frequent redressing is necessary. In order to reduce maintenance costs in a gear-manufacturing plant it was decided to provide the work blades of the centreless grinding machines with tungsten-carbide inserts. As a result, 10,000 pieces per grind of the blades are now obtained regularly, as compared with 1600 pieces formerly. In one instance 574,000 pieces were obtained per grind of the tungsten-carbide blades, as compared with less than 2000 with blades made from other materials.

The High Pressure Committee of the Department of Scientific and Industrial Research has, according to Professor G. T. Morgan, sanctioned the use of much higher pressures for autoclave work and has approved of Mr. Tongue's design of plant sufficiently strong to withstand a pressure of 3000 atmospheres. This apparatus, which has now been constructed entirely in the laboratory workshop, has been employed in a few preliminary experiments. This super-pressure plant consists essentially of a screw compression pump and an autoclave. It is housed within a steel enclosure, and all the controls are operated from outside. The pump, which has a capacity of 30 c.c. and a plunger diameter of 12·7 mm., is capable of raising the pressure of liquids or gases to the desired extent—*i.e.*, 3000 atmospheres. The cylindrical autoclave is 20·5in. long, with a ⅞in. bore; it has an outside diameter of 11in. and its capacity is 110 c.c. Heating, effected by means of an oil tank, raises the temperature to about 140 deg. Cent. The forgings for the apparatus were made by Hadfields, of Sheffield, and all the pressure-resisting parts are made of nickel-chromium-molybdenum heat-treated steel.

Glowing filaments of broken electric lamp bulbs are capable of igniting fire-damp, and in a paper entitled "The Ignition of Fire-damp by the Filaments of Broken Electric Lamp Bulbs," by G. Allsop and T. S. E. Thomas, of the Safety in Mines Research Board, an account is given of experiments which have been made to determine the limits of the efficacy of the current-interrupting devices sometimes used with a view to preventing such ignition. The assumption upon which these devices are designed is that no danger of ignition of fire-damp can exist so long as the filament, if accidentally exposed, does not continue to carry a current. In fact, however, although the temperature of the filament begins to fall immediately the current is interrupted, the filament does not cool instantaneously because of the heat stored in its mass, and for an appreciable time it may remain incandescent at a temperature above the minimum temperature necessary for the ignition of fire-damp. The rate of cooling of the filament of a lamp bulb is, therefore, one of the principal factors which determine whether the filament can ignite fire-damp, and details are given of the cooling rate of filaments and of the relationship between the rating of a bulb and the time of cooling of its filament. The results of the experiments indicate that no current-interrupting device, unless it can cut off the current before the glass of the bulb is broken, can be effective for any lamps the filament current of which exceeds about 2 ampères. With smaller currents at voltages up to 6, the device may be successful, particularly with gas-filled bulbs. The paper may be obtained from H.M. Stationary Office, price 6d.

Miscellanea.

The new mines rescue station for Lancashire and Cheshire, at Boothstown, is to be formally opened on Saturday, the 11th inst.

The British Columbia Electric Railway Company, of Vancouver, proposes to construct a power plant of 4600 horse-power in the town of Bridge River. The cost is estimated at 300,000 dollars.

The construction of a coal carbonisation and natural gas plant in Regina, Alberta, at a cost ranging from 250,000 dollars to 400,000 dollars, is contemplated by a company launched by Edmonton business men.

A Swedish firm has, according to *Indian Engineering*, secured the contract for the construction of a railway across Persia from the Caspian Sea to the Gulf of Basra. The new line will be about 1000 miles long, and will take five years to build.

It is said that the paper-making machine which is being made by Walmsleys (Bury), Ltd., for the Kemsley mill of Edward Lloyd, Ltd., will be the largest in the world. It is to have a width of 320in., and will have an output of 1000 tons of newsprint a week.

A sodium sulphate refining plant is to be put up at Inglebright Lake, 40 miles north of Maple Creek, Saskatchewan, by Metallics and Non-Metallics, of Toronto. The initial expenditure is to be 150,000 dollars, but the plant will probably be extended at a cost of 1,000,000 dollars.

It is expected that coal drawing at the Cowpen Company's new pit at Blyth, which is close to the loading staiths, will be commenced early in December. At the outset a yield of about 500 tons per day is expected. It will be a progressively increasing addition to the trade of the port.

The Lords Commissioners of the Treasury have approved a scheme submitted to them by the Import Duties Advisory Committee for the allowance of a drawback at the rate of 6s. 2d. a ton in respect of the duty paid on solid coal tar pitch used in the manufacture of coal briquettes.

It is reported that the firm of Siemens-Schuckert, of Berlin, has, through its subsidiary, Siemens-Schuckert (Ireland), been awarded the major portion of the contract for the erection and equipment of the three new sugar beet factories at Thurles, Tuam and Mallow. The value of the contract is stated to be about £1,500,000.

During the tunnelling operations for the condensing water for the King's Dock power station, Swansea, an accident occurred on the 4th inst. One man was killed and six others injured by an explosion, the cause of which has not yet been determined. The tunnels are about a mile long and have passed through several coal seams.

The effect of the tariff on steel was shown at the meeting of the Tees Conservancy at Middlesbrough on the 6th inst., when it was stated that during the twelve months ending October 31st only 14,664 tons of steel were imported, against 126,759 tons in the corresponding period last year. The iron and steel works on the North-East Coast are busier than they have been for several years.

A fuel research survey paper dealing with an investigation into the accuracy of routine analytical determinations on coal and coke has been published by the Department of Scientific and Industrial Research. Most of the results were obtained from investigations carried out jointly at Newcastle by the staff of the Department's coal survey laboratory and the staff of the Northern Coke Research Committee.

Work is to be started immediately on the new £527,000 bridge over the Forth at Kincardine. The erection of the bridge is anticipated to take two years. The bridge is to be half a mile in length, with twelve 50ft. spans and two central spans of 150ft., which will be pivoted to permit the passage of shipping. The bridge roadway will be 30ft. above high-water level. The steelwork is to be supplied by the Cleveland Bridge and Engineering Company.

In the course of his Andrew Laing Lecture, before the North-East Coast Institution of Engineers and Shipbuilders, in Newcastle, Professor F. C. Lea said that much had already been done by well-directed research by metallurgists to meet the pressing needs of the mechanical and structural engineer. It remained with engineers to make the best use possible of the materials available, to investigate fully their properties, and to use them with knowledge and courage when, by doing so, greater efficiency and real progress could be attained.

A new hydro-electric power station has recently been completed at Alloz by the Sociedad Fuerzas Electricas de Navarra, of Pamplona. The station is situated at the foot of a dam on the river Salada in the province of Navarra. The water stored in the reservoir formed by the dam is used only during the summer periods, primarily for irrigation purposes, and partly for power generation. The plant, which works under a head varying between 105ft. and 210ft., comprises two 6000 horse-power Francis-type turbines, coupled direct to Oerlikon 4200 kVA, 5000-V A.C. generators (375 r.p.m.). The power is stepped-up for transmission purposes to 60,000 V by two Oerlikon transformers.

Speaking at an informal meeting of the Institution of Electrical Engineers, held on October 30th, the new President, Mr. P. V. Hunter, said the case for underground cable transmission in rural areas had not received adequate consideration, and except for the opinions expressed by Dr. Ekstrom a year or two ago, the overhead transmission line had hardly been challenged. Too often comparisons of cost were made of areas and conditions very different in soil and climate, but Holland, with 11,000-volt transmission, almost entirely underground, and Switzerland with overhead lines, both found supply to rural areas a paying proposition. The Dutch system used cables of two sizes, but he believed Dutch engineers had found the larger more practical, and he suggested for rural England the adoption of a standard three-phase cable, 0·05 square in., 11 kV lead-covered, taped and compounded, thereby eliminating all variation of size and shape, and allowing for very ample supply.

KINEMATICAL DESIGN.

The general study of the motion of bodies is divisible into two parts. Kinematics, the geometry of motion, is concerned with the displacement, velocity, and acceleration of bodies. Under kinetics, or dynamics, we study the causes of motion—that is to say, the forces and resistances in action restraining a body to a specified path, and giving it its specified velocity and acceleration along that path. Briefly, kinematics deals with the movement of bodies, and kinetics with the cause of that movement. This division of the study of motion into two parts is familiar to all readers of physical text-books. For the most part, however, the division is largely of academic interest, and in practical work is speedily forgotten. Every physical problem has its kinematic and its kinetic aspect, but the conscious recognition of that fact does not materially assist us to arrive at a solution. The geometrical motion of a body, the kinematic aspect, may be specified, and from it we may be required to deduce the forces which must be in action, the kinetic aspect. Conversely, we may know the forces in action, and the problem may be to deduce therefrom the geometrical motion which will result. Kinetics is founded on Newton's laws of motion, and of universal gravitation, upon Hooke's law of elasticity, upon Boyle's and Charles' laws and upon other formalised expressions concerning the effect of force on matter. Kinematics is a branch of geometry, and excludes force and mass from its consideration. A study of the displacement, velocity, and acceleration of the piston of a reciprocating engine presents purely kinematical problems. When we pass on to investigate the stresses in the piston-rod and the connecting-rod, the reaction on the crank pin, and so forth, we enter the field of kinetics. This distinction between kinematics and kinetics may appear to be, and, in many respects, undoubtedly is, something of a refinement. It is, however, necessary to understand it if we would gather the full implications of Professor Pollard's lecture delivered last Friday before the Institution of Mechanical Engineers. His subject was "Kinematic Design in Engineering." It was a fascinating subject, ably presented, and the audience which the lecture attracted displayed marked absorption in it. The lecture had but one fault. It failed almost completely to fulfil the promise of its title. Very nearly the whole of it was devoted to a discussion of kinematic design in instrument-making. Scarcely anything was said concerning kinematic design in what, in contrast with instrument-making, and following Professor Pollard's example, may be called heavy-duty engineering. The explanation is not difficult to find. Kinematic design is in general not directly applicable to heavy-duty engineering.

As Professor of Instrument Design at the Imperial College of Science and Technology, Professor Pollard had a good personal reason for confining himself in his lecture almost wholly to examples of kinematic design in the production of instruments. Beyond this personal one, however, there was a fundamental reason why the field of the lecture should be restricted in this manner. Instrument making is a branch of mechanical production in which geometrical motion, or absence of motion, is the prime consideration. In what we have called heavy-duty engineering, the production, transmission, or resistance of force is a major factor with which accuracy of geometrical motion may or may not be combined. In other words, instrument-making is primarily kinematical in its outlook; engineering, as distinct from instrument-making, is essentially kinetic. In the light of the definitions of these two conceptions, it seems to be almost a contradiction in terms to associate the word kinematic with engineering design. It can be granted that the border between instrument-making and heavy-duty engineering is very indistinctly defined. A large astronomical telescope, or an 18ft. measuring bench, such as that at the National Physical Laboratory, although instrumental in its function, is a product which comes well within the field of heavy-duty engineering in so far that its own massiveness imposes on the designer the necessity for considering questions of force and stress. Again, certain small high-precision machine tools —such as the Hilger lathe, which we described in our issue of December 17th, 1926—closely approach the category of instruments, since the great accuracy of motion which is required dominates the provisions made to enable the machine to fulfil its duty as a cutting device. A lens-grinding machine perhaps provides the most striking example of an appliance which, although its primary duty is the exertion of force, is essentially an instrument as judged from the aspect of geometrical motion. Apart, however, from this field, within which the two categories overlap, the distinction between the kinematical instrument and the kinetic machine is fundamental not only on what may be deemed academical grounds, but for reasons which are thoroughly practical. The case of a shaft mounted to rotate in ball bearings provides a good illustration. Kinematically, the shaft may be supported in two bearings, each containing three balls set at 120 deg. apart. If the bearings are in excess of two, or if the number of balls in each exceeds three, redundancy will be introduced into the support of the shaft and ambiguity will exist concerning the axis of rotation. In this connection it may be noted that the use of rollers instead of balls is kinematically equivalent to the use of more than two ball bearings. For instrumental purposes two three-ball bearings might be used to support a shaft which is to be free to rotate. If, however, the shaft has to transmit not merely motion but force, and if its own mass is sufficiently great to introduce secondary forces which are not negligible—in a word, if the shaft is part of a kinetic machine and not of an instrument—then its support on two three-ball bearings may be ruled out as impracticable. It is impracticable because of the intensity of the pressure which would be thrown upon the areas of contact between the shaft and the balls or the balls and their races, and because it fails to provide the mechanical surfaces necessary for the establishment and maintenance of hydro-dynamical lubrication. To reduce the bearing pressure, and to provide the means for hydro-dynamical lubrication, it is necessary to introduce redundant constraints; in other words, to depart from the principles of kinematic design. We have, in fact, to multiply the number of points of support until they reach the infinite number provided by a plain journal bearing. To take another illustration, let us suppose that we have to devise a table constrained to slide horizontally in a straight line. Kinematically, the constraints will be completely provided by six balls, three between the table and its bed, two between one edge of the table and the edge of the bed, and one between the edges on the opposite side. A seventh ball or bearing point introduced anywhere would be redundant, and would create the possibility of a small degree of freedom additional to that which alone is desired. For instrumental purposes, a six-ball supporting system would be satisfactory, since geometrical motion and not force and mass is the prime consideration. If, however, the table is the table of a planing machine, the six-point system of support becomes impracticable, because, with the introduction of forces and masses as prime factors in the problem, we are compelled, as before, to consider bearing pressures and lubrication. In addition, in this case, the practical possibility of the sagging of the table, under its own weight and the load upon it, is a factor militating against the adoption of the kinematically ideal system of support.

The general principles of kinematic design are not new. They were taught and practised to a considerable extent by Lord Kelvin, who, apart from being a great natural philosopher, was, significantly, an instrument maker rather than an engineer. Professor Pollard has done a very great deal to systematise the principles of kinematic design, and to secure its adoption among instrument makers. Although he maintains that "the advantages of kinematic design weigh heavily in favour of its consideration in relation to heavy-duty mechanisms and structures," it is, we think, symptomatic that in the whole course of his printed address he mentions only two instances in which the principles of kinematic design have been applied to engineering outside the field of instrument making, the three-point system of supporting motor car engines and clamps for tubular steel scaffolding. We would not, however, have it thought that, in our opinion, the lecture, addressed as it was to a body of engineers rather than of instrument makers, was without practical importance. On the contrary, we are convinced that it will, or can be made to, serve a most useful end. Engineering, it may be definitely asserted, depends for its progress in a most intimate manner upon the instrument maker and the instrument user. It is sufficient in this connection to recall the vital services rendered during the war by the National Physical Laboratory to the engineering industry, struggling to adapt itself to the new and in many cases exacting conditions which it was called upon in the country's interests to face. The engineer, if he is not an instrument user himself, depends upon the services of those who are. Many engineers are users of instruments, and not a few are called upon at times to make and occasionally to design instruments for the use of others or for their own special needs. It is therefore desirable in these circumstances that the engineer should have a proper and full understanding of sound principles of instrument design, and in that respect there can be no doubt whatsoever that the kinematical methods expounded by Professor Pollard provide the only true guidance. Furthermore, a knowledge of the principles of kinematic design is of value to the designer of heavy-duty engineering products. He may never or rarely be able to apply them fully and unmodified in practice. A knowledge of them will, however, go far to clarify his mind when he is faced with complicated conditions, and will enable him to discriminate wisely between the merits of two or more alternative plans.

Continental Industrial Plans.

The signs of recovery in the British engineering industries are generally taken as indicating a gradual return to normal conditions, and there is no reason for supposing that manufacturers will not get back a fair share of foreign trade in the future. If they succeed in doing so it can only be by adapting themselves to circumstances which have entirely changed the conditions under which business can be transacted with some foreign markets, notably those that have developed industries and are narrowing down the possibilities of trade for manufacturers in other countries. It is curious, therefore, to observe the tendency in France, where a definite plan to revive trade by international collaboration was revealed in the message which Monsieur Sarraut read to the Chamber of Deputies last week when presenting the main lines of the new Government's programme.

Whatever may be the fate of Governments, the plan will doubtless remain. It was prepared after consultation with industrial interests, and reflects ideas that have been crystallising for a long while. Monsieur Sarraut has had an extensive experience of the Far East, and he falls in with the view that Eastern markets are being lost to European manufacturers, who, he says, are reduced to the necessity of competing amongst themselves under conditions of monetary chaos. So far as engineering products are concerned, there appears to be no reason for supposing that countries in the Far East will be able to dispense with, say, Western machinery, even though Japan should extend considerably her manufacturing equipment, and the belief entertained abroad that Russia is looking more particularly to Asiatic markets is not likely to disturb unduly British engineers. Nevertheless, Monsieur Sarraut is of the opinion that Europe is "unconscious of the perils" surrounding it, and the plan of his Government is to consolidate the industrial and commercial situation of his country and to be ready at an opportune moment to collaborate with other nations for a general economic reconstruction. Temporary measures for stimulating activity, such as the programme of national public works, are retained in the plan, the chief feature of which is the use to be made of import quotas as a means of promoting exchanges with other countries. The quotas had a disastrous effect upon the French export trade so long as they were applied indiscriminately without system, but they are now recognised as offering the only practical means, under present circumstances, of negotiating commercial agreements. They obviously imply limitations, for the more a country seeks to supply its own needs the less it is able to take in exchange for the sale of its goods and produce. Some foreign markets will presumably have to be sacrificed for the country's good. This plan is to be built up in a solid foundation of colonial development. A great deal of work has been accomplished in Africa with a view to the production of raw materials, and for a long time to come this work will continue to provide an outlet for engineering activity. The belief that France can become largely self-supporting with an African market for home manufactured products capable of almost unlimited expansion is not entertained by those who know the colonies best. A sparse population over a vast territory has little need of European goods, or the means to buy them. A colonial development on the scale contemplated by the French can only be effected by Europeans with the aid of machinery in the laying out and cultivation of plantations. All attempts to do this so far have failed financially. The native contribution is comparatively small and is limited to natural products requiring little labour. At the best, colonial development is a slow process depending upon the world prices of raw material. It is doubtful, therefore, whether, apart from North Africa, the idea of a dependence on colonial resources can influence appreciably the French policy in the way of commercial arrangements with other countries. Essentially French products must find an outlet to foreign markets, and now that the French realise their dependence upon foreign trade they are prepared, and anxious, to collaborate in any plan for a return to international trading activity on the basis of a reciprocal exchange of goods and produce.

Perhaps the most striking evolution of trade policy is that observable in Belgium, where industries are essentially exporting, and the country has therefore always pursued a liberal trade policy as necessary to its national prosperity. It has striven to maintain that policy and endeavoured to extend it by means of the Ouchy Convention, whereby the Belgium-Luxemburg Union and Holland and Denmark agreed to a progressive reduction of tariffs in the hope that other countries would follow their example. The Ouchy Convention has failed entirely in its object. Belgium has been losing trade, and is now confronted with problems that can only be solved by a modification of her economic policy. An influential committee has been investigating the situation, and has presented to the Government a report which affirms that Belgium is unable, for reasons of internal prices, to adopt an integral system of Protection, though in view of the discrepancy in values of imports and exports it has become necessary to apply a system of strict reciprocity. The way is being prepared for reciprocal agreements which may possibly become less strict in their application on a return to sound economic conditions. There are obviously great difficulties in carrying out such arrangements, because most countries are not able to offer sufficient compensation for the advantages they hope to obtain. The announcement in the French Chamber of Deputies that the country is prepared to collaborate internationally in industrial and commercial adjustments with a view to avoiding the "perils that surround us" is happily an indication that something may be attempted without undue delay.

Works Management Education, with Special Reference to the Case System. By T. H. Burnham, B.Sc., B.Com., A.M.I. Mech. E. London: Sir Isaac Pitman and Sons, Ltd. 1933. Price 7s. 6d. net.

After perusing this work we are left with the definite impression that in the art of management the days of undirected natural evolution, those days when it was usual to adopt a *laissez faire* attitude, have for ever passed, and it is now recognised that management has become a profession in itself, the aim of which is "to guide an undertaking towards its objection with the greatest economic use of the available resources, both human and material."

If this be admitted, there can be no doubt that time and trouble devoted to the education of staff will be fully warranted.

In dealing with professional training for managers (Chapter I.), the author rightly affirms that most of the essential qualities of a manager, such as personality, leadership, and initiative, cannot be taught, but he claims that they can be trained and developed, although no rigid curriculum can be advocated. We are glad to see that it is asserted that as management is essentially practical, contact with industry must always be maintained, while the training will probably have to be varied to suit the locality.

Although there are not many educational centres where there is a thorough scheme of management training, at the South-East London Technical Institute a full course has been established, which is described in Chapter II. This includes not only a syllabus of lectures and mind training, but also what is called the "Case System" course. Each "case" is a definite management problem, usually obtained from some firm in the locality, and it is carefully considered by the class, which for the occasion is turned into a management committee, with the teacher in the chair. The case has been circulated several days in advance, and the works manager or other representative of the firm which made the suggestion is usually present at the meeting. The problem is discussed fully and freely, until a solution is reached and stated. The manager who has set it thereupon criticises what has been done, and proceeds to tell the students what course he actually adopted, giving his reasons. It will readily be realised that the co-operation of industry is essential to the success of such a scheme of training. Visits to the works in question are frequently arranged as a sequel to the case.

A plea for the organised diffusion of management knowledge constitutes Chapter III., and with this subject is closely associated the work of the Institute of Industrial Administration.

But if the manager needs training it becomes imperative that those on the lower rungs of the industrial ladder should also receive instruction, and so be ready to advance when opportunity arises. Chapter IV. deals with the important subject of modern foremanship training, and rightly emphasises the changed conditions that are now found in the world of manufacture. No longer is the foreman merely the skilled craftsman, expert at his particular trade, but his functions are increasingly administrative, and he becomes the important link between a number of highly specialised functions. He will always be the intermediary between men and management, with the result that the *esprit de corps* in a factory is largely in his hands, and by him the whole atmosphere of the shop may be made or marred. Considerations of this nature emphasise the necessity for training the foreman to be progressive and permeable to new ideas, as well as developing his own, and it is satisfactory to know that many technical institutes, with the assistance of local firms, arrange courses to meet this need.

Mr. Burnham has clearly made his case for management education, and in his first appendix is laid out a lecture course syllabus, covering nine main sections dealing with economics and business organisation, and thirteen with production and works management.

Appendix II., which occupies half the book, gives thirty-six different "cases" set out for consideration, the salient features being clearly enunciated, and finally the problem is stated. No solutions are given, the author's reason being that "it is impossible to reproduce them as they were progressively evolved by the students, and given orally by the managers, who were actually confronted by the problems as they arose in practice." While we appreciate his difficulties, we cannot help feeling that it would be distinctly helpful to set out at least one case in considerable detail, showing how the students arrived at their solution, and comparing it with the course actually pursued by the management of the firm concerned, explaining the reason for the difference between the two if there should be one. We should also be interested to hear if the industrialist ever confesses that the solution proposed by the students of management, who have had all the advantages of lectures and training, is definitely superior to the course he adopted.

This little book cannot be regarded as a textbook on management training, as its main object is to explain the developments in the application of the "Case System" of education in this country, and though a study of it might not make a young man a better manager, it would at least emphasise the necessity for a systematic course of study and indicate the best manner of securing it efficiently.

In our opinion perhaps the best feature of the author's proposals is to be found in his insistence on the maintenance of the closest co-operation between industry and the class room. Too often has a promising scheme—or even institution itself—started well, only to fall into the hands of the advanced theorist, the course becoming increasingly academic, until eventually it ceases to fulfil the function for which it was originally intended.

In his foreword, Mr. E. S. Byng, who is Chairman of Council of the Institute of Industrial Administration, welcomes this book as the first British "Case System" publication, and rightly stresses the importance of studying in the environment of British industry. We are in full agreement with him in his conclusion that the appearance of this volume is peculiarly opportune as a starting point for discussion, as a number of professional bodies are now paying more attention to this phase of the subject. It is considered that this work is more likely to be of value to technical institutes than to the individual.

SHORT NOTICES.

Commercial Cinematography, for Business and Commerce, Using Sub-standard Films. By George H. Sewell. London: Sir Isaac Pitman and Sons, Ltd. 1933. Price 7s. 6d.—The arrival of the 16 mm. and 9·5 mm. cinematograph films and cameras has so reduced the cost of production, and the price and bulk of apparatus, that their use is rapidly becoming a recognised form of trade publicity. The subject is now one on which the publicity departments of manufacturing firms must be informed, and it is for them primarily that this book has been written, but there is much in it that the amateur cinematographer should find useful. The author remarks that "the making of films consists of one part photography and nine parts picture making." It is probably rarely that engineering firms will go to the trouble of doing their own developing and printing—which can be done so much better by specialists—but they can with advantage take their own pictures. Mr. Sewell therefore devotes his attention to the apparatus and its use for picture taking and making, for film editing, projecting and so on. The volume may be recommended for purchase by publicity departments.

The Vitry Locomotive Testing Station.

◆

THE Office Central d'Etudes de Matériel de Chemins de Fer was constituted in 1919 by the seven French railway companies with a view, primarily, to preparing plans for standardising rolling stock. The nature of the work undertaken by the Office Central had the logical result of making it a centre of technical research in everything relating to locomotives, wagons, and railway material generally. The difficulty in the way of investigating problems of locomotive efficiency by means of the more or less unreliable data obtained from tests in actual service induced the principal engineer of the O.C.E.M., Monsieur Place, to propose the construction of a fixed testing plant. Plans for such a plant were begun in 1920, but it was not until 1929 that the railway companies were able to grant the credits necessary to put the work in hand. The site chosen for the installation is at Vitry-sur-Seine, where a building—illustrated on page 462—180ft. long and 49ft. wide was erected to house the plant. Outside this building are two reservoirs, each of 400 cubic metres capacity, for water circulation to the Froude brakes. Adjoining it are offices, a laboratory, and a shed, connected with the Paris-Orleans railway, for the locomotives to be tested, and for four dynamometer coaches which the Office Central has constructed for the use of the railway companies. Ample space has been reserved for additional plant and buildings that may be necessary to make the Vitry experimental station as complete as possible for all kinds of railway research and testing work. A sum of 16,000,000f. was allotted for this important undertaking. It is understood that close upon 10,000,000f. were spent upon the test bench, most of the remainder being devoted to buildings. The bench was designed by the locomotive department of the O.C.E.M., and constructed by the Compagnie des Forges et Aciéries de la Marine et d'Homécourt, which also collaborated in the preparation of details.

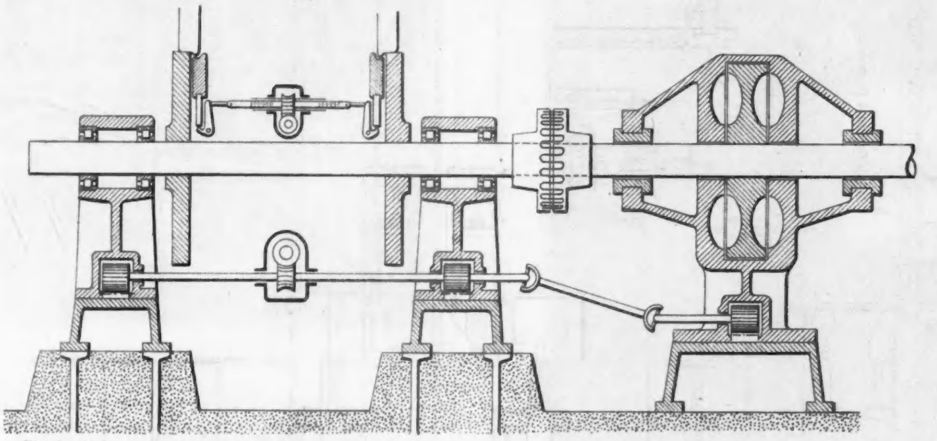

FIG. 5—CROSS SECTION OF TEST BED

The building containing the plant is a steel frame and brick structure with heavy girders capable of carrying eventually two overhead travelling cranes of 60 tons, although at present only one 25-ton crane is installed. The foundation for the bench—see Fig. 5—is composed of deep girders laid in concrete. The total length of the foundation is 105ft., and provides for a possible extension of the existing locomotive platform, which is 82ft. long. It carries two tracks built up of heavy double-tee cast iron sections planed on the top and along the edges. The sections are bolted together and each forms a wide tread with a central rack, on which are mounted pedestals carrying rollers driven by the locomotive wheels. Each pedestal has a pinion meshing with the rack, as well as small rollers that bear on the smooth surfaces on each side of the rack to take the weight of the pedestal while it is being moved. When the pedestal is bolted down to the bench for testing purposes, Belleville washers against which the rollers bear are compressed and the load is transmitted direct to the track. Each driven roller is composed of two wheels mounted on an axle. The wheels have a diameter of 1·3 m. and flat rims 140 mm. wide, and are set apart to accommodate locomotives with a minimum distance between driving wheel centres of 1·45 m. The roller wheels are keyed on axles 270 mm. diameter, carried in double-roller bearings mounted in spherical housings. These bearings also take up axial thrust. Each roller is connected by a Wellman-Bibby coupling to a Froude brake, capable of absorbing 1200 horsepower. The rollers and brake, when free on their beds, have been run at 800 revolutions per minute without showing the slightest vibration. The size of the brakes necessitates their being placed alternately on each side of the locomotive platform, so that there are two brake tracks each with a central rack. As the whole weight of the brake rests directly on the track, considerable friction has to be overcome in moving it. The pinion for adjusting the position of the Froude brake is connected by a cardan shaft with the pinion shaft of the roller pedestals, and the brake and roller are moved simultaneously. All the roller and brake units can be displaced simultaneously or separately by means of a longitudinal shaft extending the whole length of the bench and driving worm gears on the pedestal pinion shafts through dog clutches. Each clutch is put in and out of engagement by the agency of a hand wheel operated from the side of the pedestal. The longitudinal shaft is driven by a 23 horse-power electric motor through reduction gearing, which gives a very slow motion to the heavy masses to be moved.

There is a second longitudinal shaft from the same electric motor for raising and lowering the locomotive platform which is supported on cross members and jacks, these latter being given a travel of 30 mm. by the rotation of the shaft. The platform is provided with rails on which run the flanges of the locomotive wheels, while the treads overlap the rollers. Before the platform is lowered to bring the locomotive wheels on to the rollers, these latter have their distances apart adjusted to equality with those of the locomotive wheels with the aid of pointers on the roller pedestals and a scale graduated in millimetres extending the whole length of the bench. Precision of the adjustment of the rollers relatively to the wheels is obtained by means of a centering plate—see Fig. 6—consisting of a balance beam pivoted at its centre and carrying small rollers at its extremities. The small rollers rest on the wheel of the driven roller, and the beam is adjusted horizontally with the aid of a water level. It is then raised vertically by a lever until the small rollers bear against the rim of the driving wheel. Any deviation of the beam from the horizontal when it is raised is amplified by a pointer working against a graduated quadrant. Verification of the position of the wheels relatively to the rollers can be carried out at any moment during the test. The platform is next lowered 15 mm. to bring the driving wheel treads on to the rollers, and then descends another 15 mm. to clear the flanges.

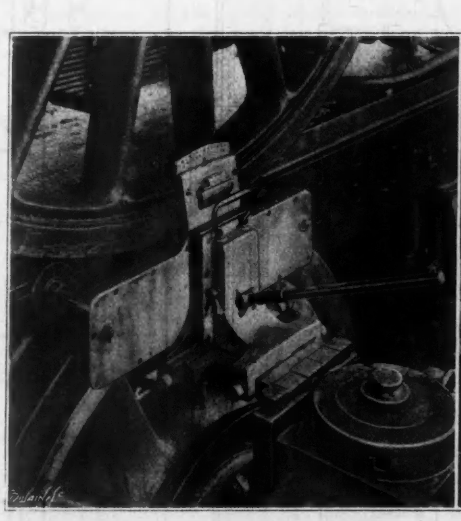

FIG. 6—WHEEL LOCATION INDICATOR

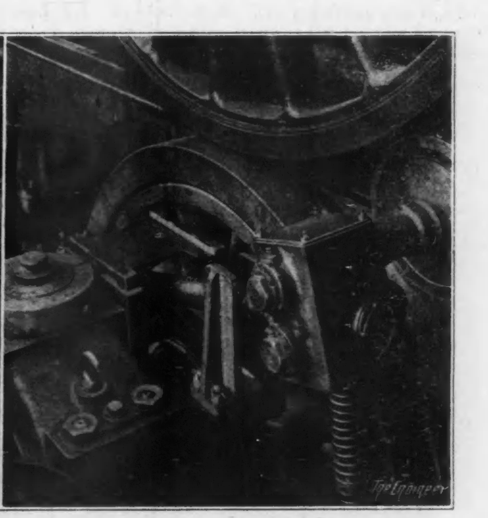

FIG. 7—FRICTION DRIVE TO APPARATUS TABLE

It is to be noted that the exact adjustment of the rollers vertically beneath the locomotive wheels is of great importance to the accuracy of the test results. If the wheel axles are slightly in advance of the roller axles, the weight of the engine will by itself exert a pull on the dynamometer just as it would if the engine were anchored to the dynamometer and were set on a downward incline. If the wheel axles are slightly in rear of the roller axles a thrust will be exerted on the dynamometer by the weight of the engine. These forces will exist whether the engine is idle or running, and will in the latter case be added to or subtracted from the draw bar pull developed by the engine. It is estimated that, with locomotive wheels of 1·5 m. diameter and rollers 1·3 m. in diameter, a locomotive weighing 100 tons would show an error of 71 kilos. in the draw bar pull for every millimetre by which the wheels and rollers were displaced from the truly vertical position. If the total pull were 7 tons, this error would amount to one of 1 per cent. It is therefore essential to be able to locate the wheels and rollers very exactly in true vertical relationship. They must be truly vertical, not simply when the engine is at rest, but when it is running in order that play in the axle-boxes and elasticity in the draw bar may be taken into account.

There are eight rollers on the bench. Six are coupled to brakes by Heenan and Froude, Ltd., three of them on each side of the platform, so that with the addition of two more brakes it will be possible to test locomotives with eight driving axles, while provision has been made to increase that number in the future, if necessary. The rollers are designed for a maximum peripheral speed of 100 miles an hour, and each roller, representing one axle, will bear a maximum load of 30 tons. The brakes are controlled from a platform equipped with speed indicators for all the brakes. The control platform also has two hand wheels for operating through bevel gearing two square shafts running along to the brakes and controlling through sprockets and chains the inlet and outlet orifices of the brakes. Water is discharged from the brakes at the rate of about 20 litres per horse-power per hour along channels at the sides of the beds into a sump from which it is raised to one of the 400 cubic metre reservoirs, the temperature of the discharge water reaching something like 80 deg. Cent. under full load. The second reservoir of the same capacity feeds cold water into a tank of 30 cubic metres capacity for supplying the brakes under a constant head. When this reservoir is empty the small tank is supplied from the other reservoir in which the water has had time to cool.

The 45-ton draw-bar dynamometer, see Fig. 3, p. 462, was supplied by Alfred J. Amsler, of Schaffhausen, together with the dynamometer table for recording the peripheral speeds of the driving wheels, tractive effort, power developed, and useful work done, the whole data being recorded on one sheet. The same type of dynamometer and similar instruments are used for the equipment of the four cars, one of 90 tons and three of 45 tons capacity, which the O.C.E.M. has had constructed for the railway companies. The dynamometer room also contains a complete set of Hoffmann and Braun instruments for recording steam, water, and air temperatures; pressure in the boiler, steam chest, at the exhaust ports, in the fire-box, and at the base of the chimney; and the temperature and the CO and CO_2 contents of the combustion gases.

The general arrangement of the dynamometer and its relationship to the engine on the test bed will be understood by reference to the drawing reproduced on page 466. The dynamometer makes use of a single cylinder employing oil as the working fluid and designed to register pulling efforts only. If it is desired to test the tractive effort of an engine running backwards, it has to be run on to the test bed with its front end towards the dynamometer. The dynamo-

THE VITRY-SUR-SEINE LOCOMOTIVE TESTING PLANT meter is constructed to withstand a pull of 45 tons, but it can be subjected with safety to momentary efforts up to 70 tons.

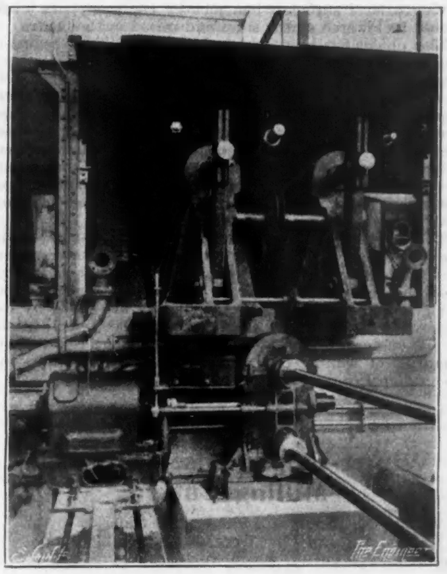

FIG. 8—SAFETY BUFFERS AND DASHPOTS

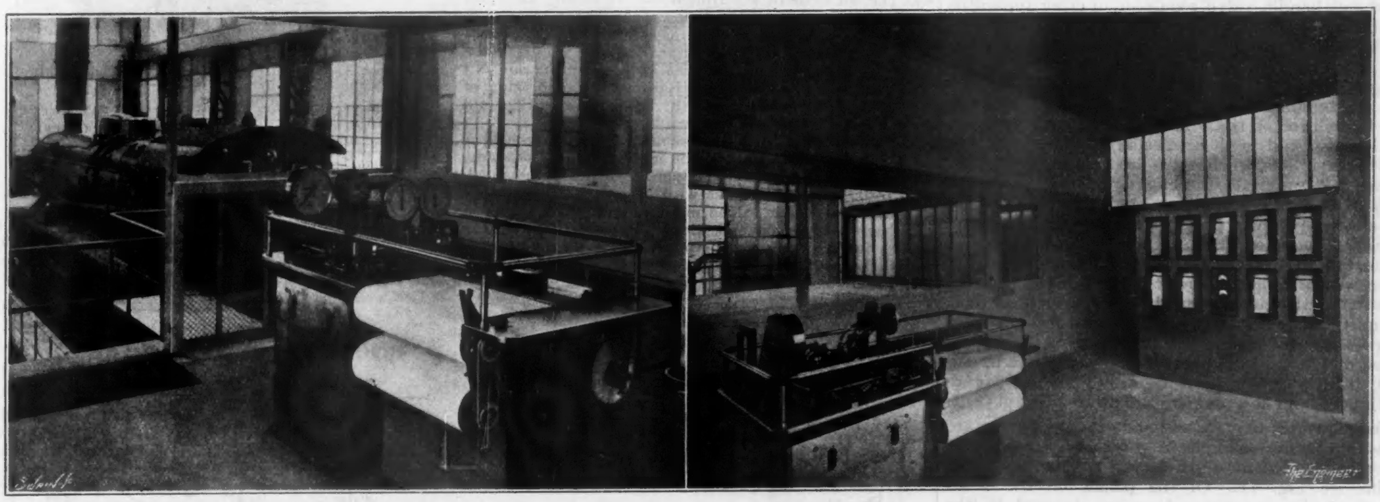

FIGS. 10 AND 11—TWO VIEWS OF THE RECORDING ROOM

The dynamometer cylinder contains a piston ground to fit with a degree of precision sufficiently great to permit packing to be completely dispensed with. In these circumstances the friction is of negligible amount, and the oil pressure set up within the cylinder becomes a measure of the pulling force exerted on the dynamometer. The cylinder bears against the rear side of a vertical beam embedded in concrete and connected to an anchoring frame which is in metallic connection with the steel work in the foundations of the test bed. The tractive effort is transmitted from the engine to the cylinder by means of a long draw bar coupled by a screwed sleeve to a short additional length which terminates in a spherical head. This head engages with a corresponding seating in the end member of a horizontal frame, the other end member of which forms one of the abutments—the face of the vertical beam being the other—between which the dynamometer cylinder is situated. The two rods constituting the side members of the horizontal frame are supported on rollers within a cast iron cradle within which they may slide easily, and by which the horizontal frame is suspended from a stirrup arranged over the top of the vertical beam. A hand wheel and screw enable the cradle and horizontal frame to be adjusted to a varying height to suit the level of the draw hook of the engine under test. The dynamometer cylinder slides against the rear face of the vertical beam and partakes of the adjustment. Parallel with the long draw bar two safety rods extend from the buffer beam of the locomotive to two vertical posts rising out of the concrete behind the vertical beam and in metallic connection with that beam. These rods are provided to prevent mishap in the event of the draw bar fracturing. Both the rods and the draw bar are provided with means for supporting them at a varying height. The oil from the cylinder is led to the pressure-measuring equipment on the adjacent apparatus table by means of hinged pipes, which accommodate themselves to changes in the vertical position of the cylinder and the cradle and frame.

Means are provided to make good any loss of oil by leakage between the piston and cylinder during a prolonged test under the influence of the force which is applied constantly in the one direction. To prevent the slow recession of the piston, and the consequent displacement of the locomotive on the rollers, a small piston pump with a very small delivery is provided. This pump is driven through reduction gearing by an electric motor, and is capable of forcing oil into the cylinder no matter what pressure may be in existence therein. Normally, this pump is short-circuited by means of its suction valve, and runs idle. As soon as any movement of the locomotive and the piston away from the position of initial adjustment occurs, a contact on the horizontal frame of the dynamometer operates a rod, and thereby closes the short circuit through the suction valve of the pump. The pump then delivers oil to the cylinder and returns the piston and the locomotive to the initially adjusted position. Immediately that position is recovered the pump is once more short-circuited. It is stated that the system is sensitive to a fraction of a millimetre of movement, and that the restoration of the oil lost by leakage is accomplished by it without a perceptible rise of the oil pressure in the cylinder.

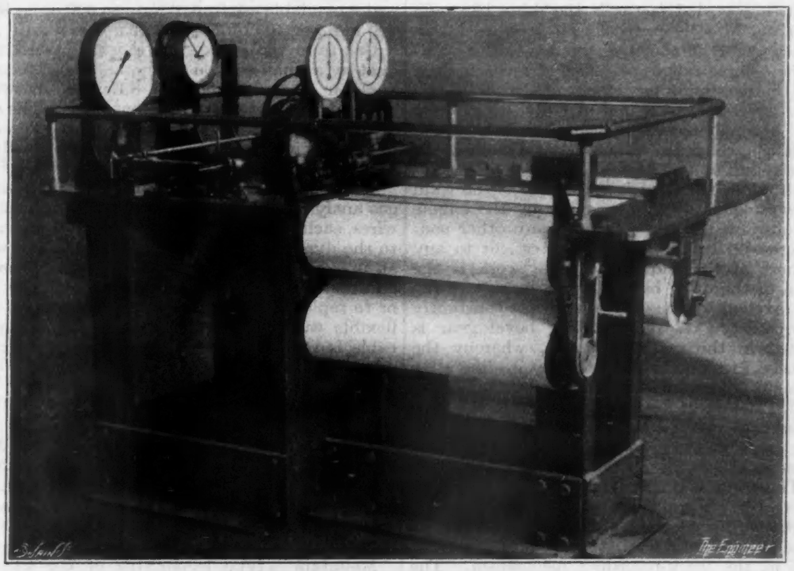

FIG. 9—AMSLER APPARATUS TABLE

Two dash pots are provided on supports anchored to the foundation immediately in rear of the engine, and are designed to suppress horizontal oscillations set up by want of balance in the reciprocating parts of the engine. As will be gathered from Fig. 8, the buffers by which these dash pots engage with the rear of the engine are adjustable as regards height to accommodate different designs of locomotive.

The calibration of the dynamometer cylinder is effected by uncoupling the draw bar at the screwed sleeve and by inserting an Amsler standardising block between the front face of the vertical beam and the end piece of the horizontal frame. The small compensation pump is then caused to deliver oil to the cylinder until any desired load is set up. The value of this load as measured by the standardising box is then compared with the indication of the recording device on the apparatus table.

Passing now to the apparatus table, we will describe the manner in which the information which it is desired to obtain is transmitted to it and there recorded. The speed of the locomotive is obtained by means of a friction disc, Fig. 7, held by a pressure spring against the tread of one of the wheels. This disc is carried on a pivoting frame attached to the bearing of one of the wheel rollers. It is exactly 1 m. in circumference and therefore rotates 1000 times per kilometre of the supposed distance run by the locomotive, no matter what may be the diameter of the wheel with which it is in contact or the degree of wear which its tire has suffered. The rotation of the disc is transmitted through shaft and gearing to a horizontal splined shaft running the full length of the test bed and from this shaft the movement is taken by further shafts and gearing to the apparatus table.

At the apparatus table—see Figs. 9 and 10—a record is made of six different factors. The six recording pens operate on a roll of paper 650 mm. wide, which can be set to move either proportionately to the "distance travelled" by the locomotive or proportionately to the time. In the first-named condition the movement of the paper is derived from the friction disc, Fig. 7, and may be set at either 4 mm., 20 mm., or 120 mm. per kilometre. In the second condition the paper is driven by an electric motor with a constant speed regulator, and its rate of movement may be either 0·2 mm., 1 mm., or 6 mm. per second. On this roll the first factor, that of time, is recorded by two electro-magnetic pens, one operated by a clock and drawing a mark once every minute, and the other operated by a small constant-speed electric motor, and making a mark every 2, 6 or 12 seconds. The second factor recorded is the "distance travelled" by the engine. The recording pen in this case is operated from the friction disc bearing against the engine wheel, and makes one mark for every 1000 turns of that disc; that is to say, for every kilometre travelled by the engine.

The third factor is the speed of the engine in kilometres per hour. This factor could, of course, be deduced from the information concerning time and distance run, given by the first and second pens. It is, however, recorded separately by means of an Amsler differential ball speedometer. This form of speedometer is claimed to work with very high accuracy. Its operative element consists of a steel ball, about 4in. in diameter, which is supported on the peripheries of two rotating discs having their planes at right angles to each other. One of these discs is driven at a speed proportional to that of the engine. The other is driven at a constant speed by a small electric motor—the same motor, in actual fact, as that which marks the seconds divisions on the time curve. Assuming that there is no slip between the discs and the sphere, the sphere will acquire from the two discs a rotation about a certain axis, the inclination of which relatively to the axis of one or other of the discs is dependent upon the ratio of the speeds of the two discs. Thus by observing the inclination of the axis of rotation of the sphere, and knowing the speed of rotation of the constant velocity disc, the speed of the other disc and therefore of the engine can be found. Means are provided for recording the speed on the paper and also for indicating it on a dial.

The fourth recorded factor is the draw bar pull, and is derived directly from the oil pressure transmitted from the dynamometer cylinder to the apparatus table. Three ranges or scales of recording are provided, the maximum movement of the pen corresponding respectively to a pull of 6, 15, or 45 tons. The draw bar pull is also indicated on a Bourdon pressure gauge, which can be used to read momentary values of the pull up to 75 tons.

The fifth factor recorded on the paper is the total effective work done at the draw bar by the engine from the start of the test—or from any other convenient zero—up to the end of the test, or to any instant short of the end. This total work is the integration of the draw bar pull with respect to the distance travelled by the engine, and is a constantly growing quantity. A reciprocating bevel gear is incorporated in the pen mechanism, whereby the pen is caused to move back to the datum line after every so many kilogramme-metres of work have been performed. The curve drawn is therefore in the form of a zig-zag confined to a limited width of the paper, about 3in., and does not, as it would otherwise have to do, extend slantwise continuously across the full width. The total work done up to any instant is determined by counting the number of zig-zags. As a check, and for purposes of taking rapid readings during the progress of a trial, a four-figure counter is embodied in the work-recording mechanism. The scale of this counter and also the scale of the zig-zag curve depends upon the scale in use in connection with the measurement of the draw bar pull. The actual integration of the draw bar pull with respect to distance travelled is performed by an Amsler ball pattern integrator.

The sixth and final factor recorded is the draw bar horse-power or the integration of the work done at the draw bar with respect to time. The integration is performed by an arrangement similar to that used in the speedometer, namely, by means of a sphere resting on the peripheries of two discs. One of these discs, as before, is rotated at a constant known speed, while the other is rotated at a speed determined by the apparatus which records the work done at the draw bar. A dial gauge is also provided to indicate the momentary value of the horse-power. One complete revolution of the pointer of this gauge corresponds to a horse-power of 1200, 3000 or 9000, according to the draw bar pull scale in use.

In addition to the six pens recording the above-mentioned data, a number of other pens are provided which may be used to record the instants at which any handle, valve, regulator, or other apparatus on the engine is operated.

The firing platform is arranged above the long draw bar and can be adjusted in height to suit different designs of engine. The coal weighed in the yard outside the building is brought inside in small trolleys, which are lifted on to the firing platform by the overhead crane, and is there discharged into a bunker moving on rollers, whence it is fired to the locomotive.

The feed water for the engine is supplied from a tank of 10 cubic metres capacity, which is filled by the alternate emptying of two tanks, each of exactly 1 cubic metre capacity. One of these tanks is graduated in litres. The 10 cubic metre tank is fitted with a gauge, whereby the water in it can be restored at the end of a trial to the same level as it occupied at the start. In addition, for checking purposes, water meters are provided on the mains. These meters, of the volumetric, piston pattern, can deal with water at a pressure of 30 kilos. per square centimetre, and at a temperature up to 235 deg. Cent.

Temperatures at various points on the engine are measured by means of electric resistance pyrometers, and are recorded on apparatus in the dynamometer cabin—see Fig. 11. Of the panels on the board shown in this engraving four are devoted to the recording of temperatures. Each of these four recording panels contains a cross-coiled galvanometer which every 10 seconds is automatically connected in succession to six pyrometers. At each connection a pen containing a different-coloured ink is operated. In this way, each of the four recording panels yields six distinguishable temperature curves on the one chart, the individual curves being composed of a succession of closely spaced dots. Two of the recording panels are devoted to the measurement of the temperatures of the hot gases at various points in the fire tubes and smoke-box. These two panels have two scales, one extending from 100 deg. to 300 deg. Cent., and the other from 200 deg. to 600 deg. Cent., a commutator being provided which allows either scale to be used at will. A third recording panel is reserved for measuring air and water temperatures, and has two alternative scales, namely, from 0 deg. to 160 deg. Cent. and from 0 deg. to 320 deg. Cent. The fourth recording panel measures saturated and superheated temperatures. It has two scales extending from 0 deg. to 250 deg. Cent. and from 150 deg. to 500 deg. Cent.

Pressures above and below atmospheric are measured by gauges placed at various points on the engine. The indications of these gauges are transmitted electrically to the dynamometer cabin, and are there recorded by means of apparatus similar to that used for recording temperatures. The six-curve pressure recorder has three alternative scales, namely, from 0 to 1·5, 0 to 10, and 0 to 25 atmospheres. In the case of the vacuum recorder, the scales available are from 0 mm. to 500 mm., 300 mm., 200 mm., or 100 mm. of water.

Gas from the smoke-box is withdrawn through a duct by a small suction pump, and delivered to a gas analyser operating on the difference between the thermal conductivity of different gases. The analyser gives the percentage of CO_2 and $CO+H_2$ present in the gases. Its indications are recorded electrically on the board in the dynamometer cabin.

In connection with the temperature, pressure and gas analysis recorders there are no fewer than ninety wires, each of 50 m. length, extending from the engine to the dynamometer cabin. Some of these wires are at present not in use, but are held in reserve for additional apparatus that may eventually be installed or to replace breakages. They are grouped into five flexible cables of eighteen wires each. Each such cable is provided with a special design of coupling, whereby all the eighteen connections can be made quickly and certainly.

At the inauguration of the laboratory on July 27th last a large party of railway engineers and directors of railway companies was received by Monsieur Renevey, director of the O.C.E.M., and Monsieur Conte, chief engineer, while Monsieur Place, to whom credit was given by Monsieur Renevey for what he had done to bring the undertaking to a successful issue, conducted a demonstration with a "Mountain" type locomotive of the Chemins de Fer de l'Est. The demonstration was carried through smoothly, the locomotive running at what was equivalent to 60 kiloms. and 120 kiloms. an hour. The Vitry testing station is available to all locomotive builders and railway companies.

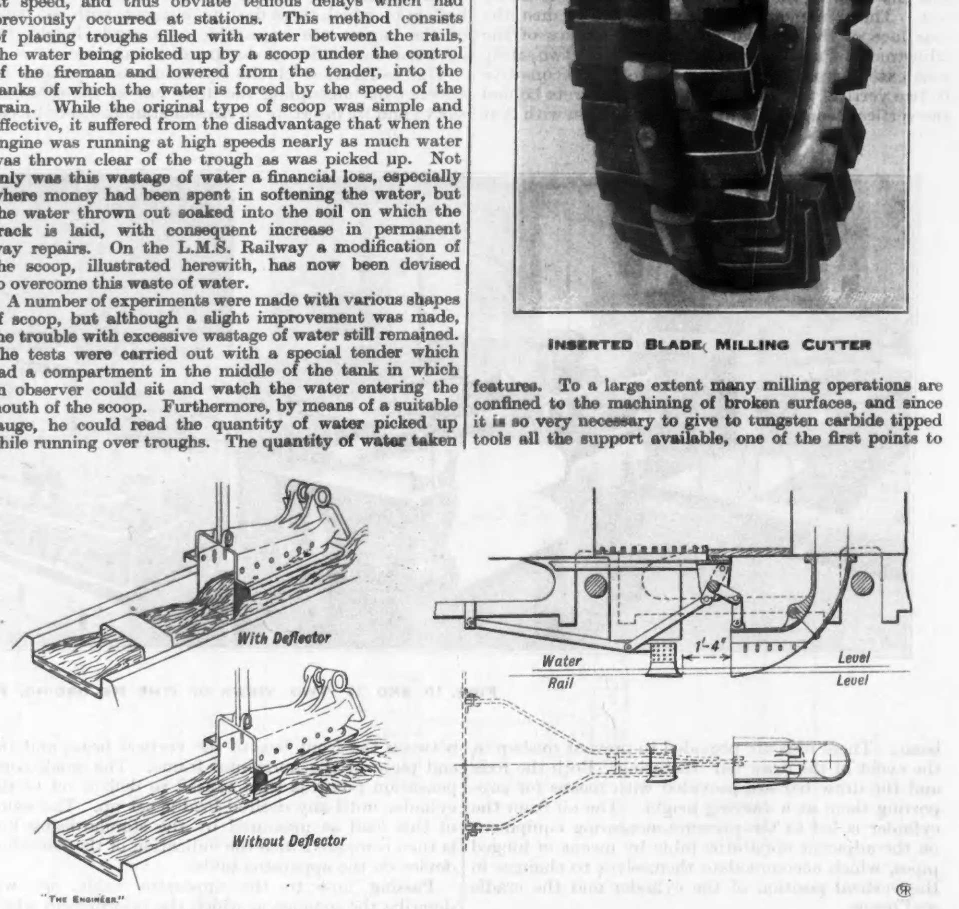
Improved Water Pick-up Gear, L.M.S. Railway.

IT is now more than seventy-five years since Mr. John Ramsbottom, locomotive engineer of the London and North-Western Railway, invented his well-known method whereby locomotives were enabled to pick up water while at speed, and thus obviate tedious delays which had previously occurred at stations. This method consists of placing troughs filled with water between the rails, the water being picked up by a scoop under the control of the fireman and lowered from the tender, into the tanks of which the water is forced by the speed of the train. While the original type of scoop was simple and effective, it suffered from the disadvantage that when the engine was running at high speeds nearly as much water was thrown clear of the trough as was picked up. Not only was this wastage of water a financial loss, especially where money had been spent in softening the water, but the water thrown out soaked into the soil on which the track is laid, with consequent increase in permanent way repairs. On the L.M.S. Railway a modification of the scoop, illustrated herewith, has now been devised to overcome this waste of water.

A number of experiments were made with various shapes of scoop, but although a slight improvement was made, the trouble with excessive wastage of water still remained. The tests were carried out with a special tender which had a compartment in the middle of the tank in which an observer could sit and watch the water entering the mouth of the scoop. Furthermore, by means of a suitable gauge, he could read the quantity of water picked up while running over troughs. The quantity of water taken from the troughs was determined by measuring the quantity of water which had to be put into the troughs to refill them to the proper level after the engine had passed over them. During the tests with the various shapes of scoop it was noticed that the water piled up on each side of the scoop and escaped over the edge of the trough. It, therefore, appeared that if the level of the water could be lowered between the scoop and the inside of the trough, the wastage would be reduced. It was not possible, however, to reduce the level of the water at the side of the trough by the simple expedient of having less water in the trough, as this would have reduced the quantity of water being picked up. In other words, it was realised that what was required was that instead of the water having a level surface when met by the scoop, its level should be lowered at the sides and raised in the centre.

This object has been achieved in a very simple manner by placing a deflector about 1ft. 4in. in front of the scoop, this deflector having two vertical vanes which project down into the water, the vanes being somewhat closer together at the back than at the front. As this deflector moves through the water in advance of the scoop, it has the effect of throwing the water inwards so that the water is heaped up at the centre of the trough and lowered at the sides, with the result that not only is the wastage reduced, but a larger amount of water is picked up than with the ordinary apparatus.

The deflector is raised and lowered simultaneously with the water scoop. Its effect on the wastage of water varies in accordance with the speed of the train, but assuming that the scoop is kept in for the whole length of the trough, then about 400 gallons of water are saved by its use every time water is taken. The device, when fitted to all engines with water pick-ups, should reduce the quantity of water which is supplied to the troughs by about 20 per cent.



ARRANGEMENT AND EFFECT OF IMPROVED WATER PICK-UP GEAR

Wimet-Tipped Inserted Blade Milling Cutter.

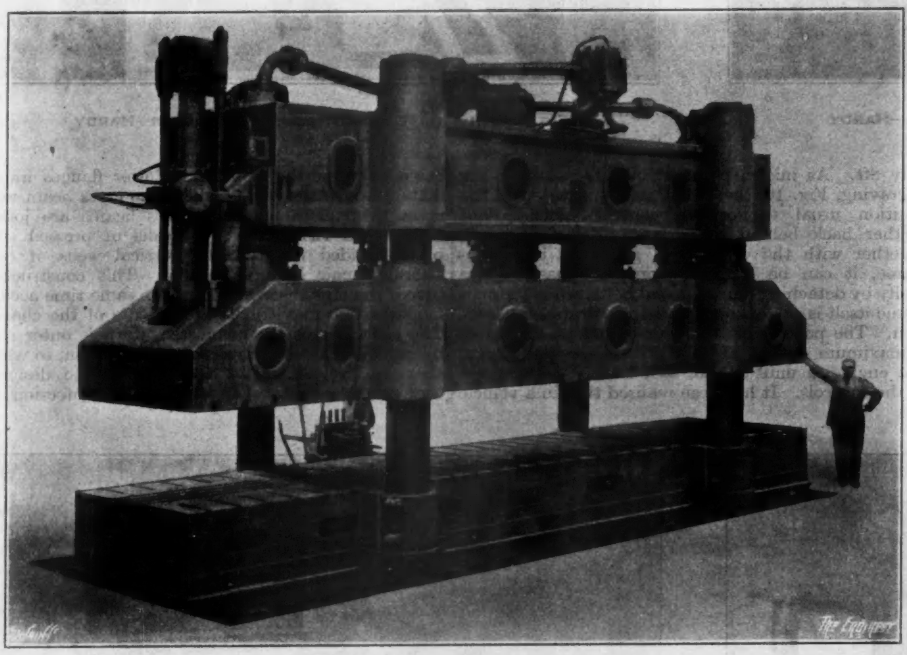
THERE has just been placed on the market by A. C. Wickman, Ltd., of Coventry, an inserted-blade, Wimet-tipped milling cutter, which embodies several interesting features. To a large extent many milling operations are confined to the machining of broken surfaces, and since it is so very necessary to give to tungsten carbide tipped tools all the support available, one of the first points to

INSERTED BLADE MILLING CUTTER

require attention in the design of a tipped inserted-blade milling cutter is a maximum number of blades rigidly supported and securely locked in the cutter body. Also, owing to the brittle nature and expense of cemented tungsten carbide, the finest possible individual adjustment must be provided to each blade. The clamping of the blades must be arranged to preclude any type of wedging action which might cause the body to distort and upset the rigidity of the cutters, or necessitate the use of force to remove tightly locked blades or clamping screws to the detriment of the cemented tungsten-carbide-tipped blades. The new design includes the simplifying of the clamping arrangement of the blades. It will be noted from the accompanying engravings that two blades are held in position by one clamp, and can be removed or adjusted by loosening one screw with a key. The shanks of the blades are provided with serrations which match serrations on the underside of the clamps. This arrangement makes the adjustment of the blades very simple, besides providing for a very rigid lock and support. Adequate chip clearance has been provided. The Wickman Wimet-tipped inserted-blade milling cutter is made in seven sizes from 3½in. to 10in. diameter; any special sizes can be made to order. The 10in. size contains twenty-six blades. Cutters up to 7in. diameter are made to suit standard arbors for face cutters, while cutters above 7in. diameter are arranged to be attached directly to the spindle of the American standard type.

A Large Hydraulic Press.

The large hydraulic press illustrated was made by Fielding and Platt, Ltd., of Gloucester, to the order of Rubery, Owen and Co., Ltd., of Darlaston, and has been specially designed for the pressing of heavy motor chassis for commercial and private vehicles of all kinds. It gives a load of 1500 tons, but where the work does not necessitate so high a pressure, it may be used at 900 or 600 tons respectively. The working faces of the tables are 30ft. long by 6ft. wide, and in the lower table are arranged ten ejecting rams, giving a total ejecting pressure of 200 tons. Holes are provided over the face of the bottom table for carrying the necessary discharge pins, so that any irregular shape of chassis can be dealt with. Water-saving valve arrangements are provided so that accumulator pressure water is only used to do the actual pressing operation; and automatic suspension gear is fitted for holding the moving table in the top position when pressure is shut off from press.



1500-TON PRESS FOR HEAVY MOTOR CHASSIS

Automatic Clutch for Motor Vehicles.

In our review of the leading features of the Motor Car Show at Olympia, in our issue of October 20th, reference was made to a new automatic clutch which is being fitted to the Riley cars. This clutch is the invention of Mr. Noel B. Newton, of Newton and Bennett, Ltd., Valetta-road, Acton, W.3, and depends for its operation on centrifugal force. Its construction will be followed by reference to the sectional drawing, in which 1 is the fly-wheel on which is mounted a steel sleeve 2. Sliding over this sleeve is a casting 3, usually made of a zinc alloy, which carries a central bearing 4, in which the presser plate 5 moves longitudinally, being held away from the fly-wheel by springs 6. The casting 3 carries bosses 7 to accommodate one end of the governor weights 8 and also spring cups 9 to receive the internal springs 10. The clutch proper is of the multi-disc type, having four inner discs 11 faced with Ferodo or other similar material. The outer steel discs 12 run on six hardened steel pegs 13, whilst the inner plates 11 slide on the spline 14.

The operation of the clutch is as follows :—The member 3 is moved towards the fly-wheel 1 by the influence of the centrifugal force set up by the governors 8 at a predetermined speed controlled by the static loading of the outer springs 6. After ¼in. of movement the presser plate 5 comes into contact with the friction discs 11, in the neighbourhood of an engine speed of 650 revolutions per minute. As the speed of revolution increases, the centrifugal force acting upon the governor weights 8 pulls up the inner springs 10, and the torque is overcome in the neighbourhood of 1100 revolutions per minute, when the member 3 becomes definitely engaged with the fly-wheel sleeve 2. This gives a load on the discs 11 and 12 of approximately one and a half times the necessary torque to be transmitted, and also allows for plate wear to be taken up by the inner springs 10 without altering the governor position.

AUTOMATIC CENTRIFUGAL CLUTCH FOR MOTOR CAR

The complete unit operates automatically, and if the car is fitted with a self-changing gear-box, there is no need for the driver to operate the usual pedals.

Centenary of Lancashire Engineers.

There are not many engineering firms that date back a hundred years, as is the case with Hick, Hargreaves and Co., Ltd., Bolton, which celebrated its centenary by a dinner in Manchester on Thursday, November 2nd. There are even fewer firms that can claim a more interesting experience as regards their products, which have covered a very wide range of mechanical engineering, including locomotives, marine engines, stationary engines, steam turbines, condensing plants, feed heaters, and air compressors.

The firm was founded in 1833 by Benjamin Hick, with the title of Benjamin Hick and Son. Hick served his apprenticeship with Mathew Murray, Leeds, one of the leading firms of engineers at that period. He subsequently left Leeds to join Messrs. Rothwell and the firm of Rothwell, Hick and Rothwell was formed. At the age of forty-three Hick severed his connection with this firm to establish a business with his two sons on the site of Hick, Hargreaves' present premises. The new firm of Benjamin Hick and Son soon earned a high reputation as power engineers and, like other engineers in those non-speculative days, had to be prepared to undertake work of every description for use in factories, mines, railways, and for marine purposes.

Benjamin died at the age of fifty-two in the year 1842, and his elder son John took over the business, along with Mr. William Hargreaves, and the title of the firm was changed to Hick, Hargreaves and Co. Under the joint management of these engineers the firm made good headway. In 1868 John Hick turned his attention to politics and was elected Member of Parliament for Bolton, and retired from the firm and William Hargreaves became sole proprietor, which he remained until his death in 1889, when the business was converted into a private limited company. It was carried on by his three sons, each successively becoming chairman of the board of directors.

One of the earliest activities was the construction of locomotives, of which a large number was built between 1833 and 1855, the drawings of many of which are still in existence. In 1850 the building of marine engines was undertaken, and amongst the orders executed were two sets of simple direct-acting jet condensing paddle-wheel engines for H.M. steam frigates "Alphonse" and "Amazonas," the cylinder diameters of which were 68in., the stroke 60in., and the rated horse-power 300. These were followed by two sets of simple direct-acting inverted screw propeller engines for the Mediterranean steamers "Nile" and "Orontes," with cylinders 47½in. diameter and 54in. stroke. But it is in connection with mill engines that Hick, Hargreaves and Co. were chiefly identified. By the introduction of the Corliss valve gear applied to horizontal slow-speed engines, the firm made a decided success for this gear, which reduced the steam consumption to a very low figure, while the governing was brought to the high state of perfection which was necessary for cotton mill driving. The demand for higher steam pressures and powers led to the development of the compound engine, and in the year 1881 a 4000 horse-power engine of the cross-compound Corliss type was built for a boiler pressure of 100 lb. per square inch. The "life" of these Lancashire mill engines has not yet been determined, but it is interesting to note that this 4000 horse-power engine, after twenty-seven years' working, was fitted with a smaller high-pressure cylinder because the boiler pressure was raised to 150 lb. per square inch.

The next development in connection with cotton mill driving was the introduction of the rope drive to replace the old bevel gearing, and in this branch Hick, Hargreaves took a prominent part. Early in the present century the use of superheated steam led to the introduction of the drop valve engine and later the Uniflow engine, an interesting example of which is one of 1750 I.H.P. constructed in 1930. The gradual decline in the demand for slow-speed engines caused the firm to branch out into other fields of activity, and the most important of these is the introduction of the two-stage steam jet air ejector in 1916, when the manufacture of high vacuum condenser plants was begun. Since their first introduction Hick, Hargreaves and Co. have supplied some of the largest condensing plants in this country, the latest being the two 75,000-kW plants at Barking power station. Other manufactures in recent years have been evaporators, deaerators, feed heaters, rotary water strainers, steam turbines, and air compressing plant.

At the centenary dinner mentioned above Mr. W. D'Arcy Madden, M. Inst. C.E., presided, and in reply to the toast of "Hick, Hargreaves and Co., Ltd.," proposed by Mr. W. B. Woodhouse, past-president of the Institution of Electrical Engineers, said there was a general belief that the first rays of the sunrise of better times were becoming visible, and there was justification for returning confidence.

The first shipment of Saskatchewan salt, taken from the Simpson salt well, about 80 miles from Saskatoon, is, says *Canada*, ready for distribution. More than seven years ago a company drilled for oil and about two years ago secured a salt brine deposit. The brine is being vaporised into salt by the Simpson Oil Company. A well is being drilled about 1¼ miles east of the salt well, where it is hoped to tap gas, to be used at the salt well for vaporisation. The industry thus closely resembles that of Szechuan. With the profits from the salt the company will continue its search for oil in a field that geologists have said has good possibilities for the discovery of oil.

Commercial Motor Transport Exhibition.

No. II.

(*Continued from page* 430, *November 3rd.*)

HARDY MOTORS, LTD.

THE chief exhibit on the stand of Hardy Motors, Ltd., of Southall, and one of the most attractive in the Exhibition, is the railcar we described fully and illustrated two weeks ago. Since that occasion, however, more photographs of the vehicle have become available, and we reproduce herewith in Figs. 8 and 9, two interior views showing respectively the passengers' and driver's compartments. The former shows very well how much window space there is and how the seating accommodation is arranged. In the centre of the coach there is a wide vestibule with large swing doors for access and exit at platform level. In addition, as we mentioned in our previous article, a trap in the floor can be raised opposite these doors exposing steps to rail level. The illustration of the driver's compartment gives an excellent impression of the wide degree of visibility he enjoys. At a glance it might be thought that the controls are not arranged to the best advantage, for two of the levers appear to be set rather far from the seat. In fact, however, these two levers are just those which are most seldom used, the hand brake and the reversing lever. The former is more or less an emergency device, and is also used when the vehicle is to stand for long periods without the engine running. In normal running, the vacuum brake finger lever, which, in the engraving is hidden from view behind the seat, is used. As for the reversing lever, on entering the cab at the terminus to perform the return journey, the driver merely pushes it forward and subsequently never interferes with it until the journey is completed. As a matter of fact, the exaggerated perspective of the photograph gives a quite incorrect impression of the distance of the levers from the driver's hands, as we found for ourselves at the Exhibition by sitting in the driver's seat. The pedal to be seen in the engraving is the accelerator, and the gear selector lever of the Wilson gear-box is also just visible.

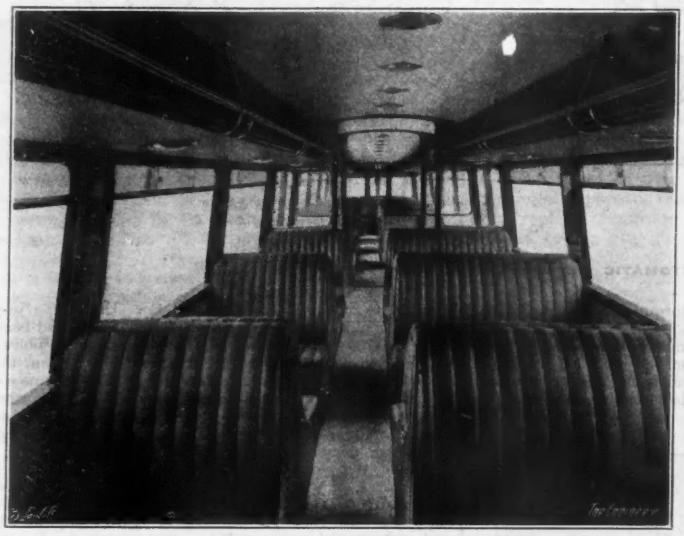

FIG. 8—INTERIOR OF 69-SEATER RAILCAR—HARDY

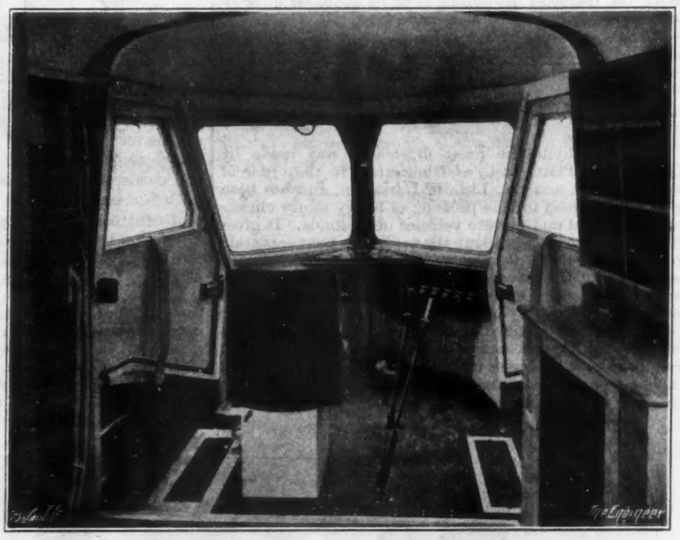

FIG. 9—DRIVER'S COMPARTMENT OF RAILCAR—HARDY

COMMER CARS, LTD.

Amongst the exhibits of Commer Cars, Ltd., of Luton, one of the newest productions, the "Pug" 2-tonner, by reason of some of the novel features in its design, deserves particular mention. It has been designed especially for the economical handling of loads in congested areas, and has the remarkably small turning circle of 33ft., although its overall length is 14ft. 7in. The wheel base, however, is only 8ft. As might, perhaps, be inferred from the engraving, Fig. 10, the engine is not situated in the position usual to forward control vehicles, but further back behind the driver. Being mounted, together with the clutch and gear-box, in a sub-frame, it can be dropped from the chassis quite easily by detaching four nuts and bolts, while the sub-frame itself is carried on a three-point rubber suspension. The power unit has four cylinders, and gives a maximum output of 44 H.P. If the position of the engine is unusual, so, too, is the arrangement of the controls. It has been realised that in a vehicle intended for local deliveries easy access to the cab is a matter of some importance. The controls are so arranged that there is nothing to inconvenience the driver or his mate in entering or leaving the cab from either side. For instance, the steering wheel is mounted on a horizontal steering column, while the brake and gear levers are placed centrally in the cab. It will also be noticed from the engraving that the floor of the cab is conveniently low.

One of the most interesting features on this stand is the entry of the oil engine into a small horse-power class, for a 2-ton "Centaur" drop-sided lorry, with a Perkins compression-ignition engine developing 45 B.H.P. is shown. Besides this particular chassis we understand that the 1½-ton "Raider" can also be supplied with an oil engine drive.

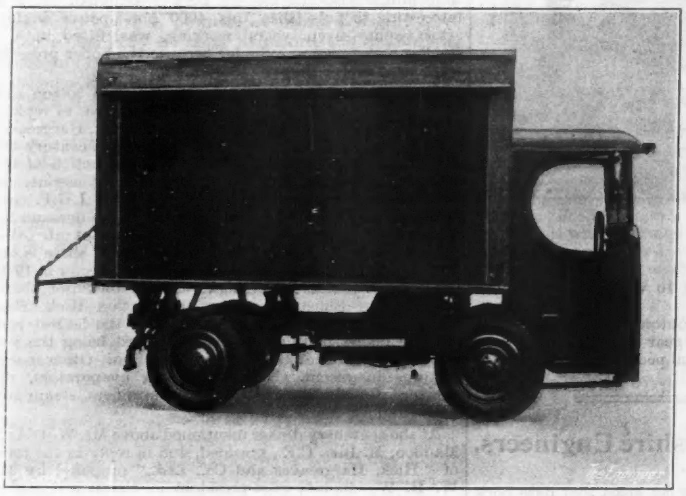

FIG. 10—THE "PUG" TWO-TONNER—COMMER

SIR W. G. ARMSTRONG, WHITWORTH AND CO., LTD.

The system of wagon building developed by Sir W. G. Armstrong, Whitworth and Co., Ltd., of Newcastle-on-Tyne, takes on a particular interest as the result of recent legislation, which taxes lorries on tare weight and at a considerably increased rate. It is claimed that the "Ironclad" lightweight body can show a saving in weight over more conventional forms of about 20 to 25 per cent. A photograph reproduced in Fig. 11 gives a general impression of the method by which the body is constructed. The framework of the body is built up of high tensile pressed steel sections joined together by electric welding. The cross beams, which form the main members of the structure, are each pressed from one steel sheet, lightening holes being provided. Vertical compression members are welded into each cross beam between the upper and lower flanges immediately above the points where the cross beam rests upon the chassis, and the cross beams are joined together in the centre by means of pressed steel plates welded between the vertical webs of each alternate pair of cross beams. This construction braces the cross beams, and at the same time accommodates the unavoidable movements of the chassis. The cross beams are connected at their outer ends by one-piece steel side rails of angle section, to which they are welded. The side rails are so designed that the horizontal flange forms a protection for the top edge of the side sill. Support for the rear portion of the body overhanging the chassis is provided by pressed steel gussets welded to the rear cross beam, and to the rear rail, the latter being of similar section to the side rails to which it is welded at the rear corners. The bottom flanges of the cross beams are connected longitudinally by means of two flat steel strips welded to the cross beams immediately above the chassis members. The floor is of oak board, 1in. thick, bolted down to the cross beams, and the side rails are of ash inserted into the steel side rails and secured by bolts passing vertically through the ash packing and the top flange of the

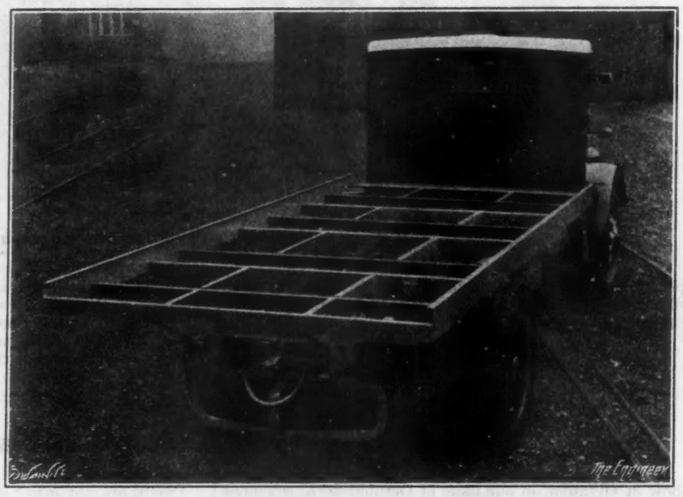

FIG. 11—"IRONCLAD" FRAMEWORK CONSTRUCTION—ARMSTRONG

steel side rail. Protection for the rear edge of the floor is provided by inserting the floor boards underneath the flange of the rear rail. Stout steel rope hooks are welded to the ends of the cross beams. The drop sides and taildoor each comprise first quality plywood panels, $\frac{7}{8}$in. thick, built into a light steel channel frame and stiffened with steel vertical battens, the whole of the steel framing being welded together after insertion of the plywood panels. This construction is applied also to trailers and examples are to be seen on the stand.

Crossley Motors, Ltd.

On the stand of Crossley Motors, Ltd., of Gorton, Manchester, there is a representative range of passenger and goods vehicles fitted with the Crossley heavy-oil engine and Crossley petrol motor. One of the larger exhibits is the double-deck chassis fitted with a "V R 6" six-cylinder Crossley oil engine, which, the makers claim, operates without smoke or odour. A side view of this engine is reproduced in Fig. 12, while in Fig. 13 we illustrate a rear view of a typical Crossley chassis.

The new designs of chassis include the "Beta" 4 to 5-ton vehicle, with a four-cylinder V R 4, 66 B.H.P. engine, and a 3 to 4-ton "Delta" vehicle, engined with a four-cylinder petrol motor. The four-cylinder oil engine is similar, except in the number of cylinders, to the six-cylinder unit we illustrate.

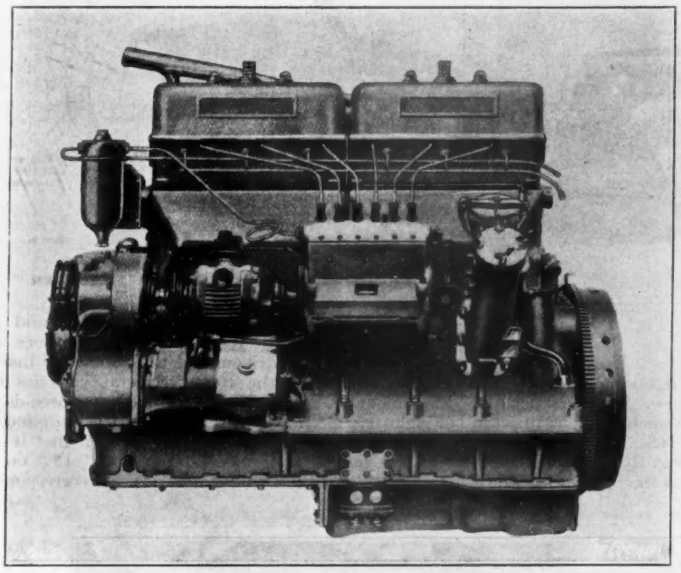

FIG. 12—100 B.H.P. "VR 6" OIL ENGINE—CROSSLEY

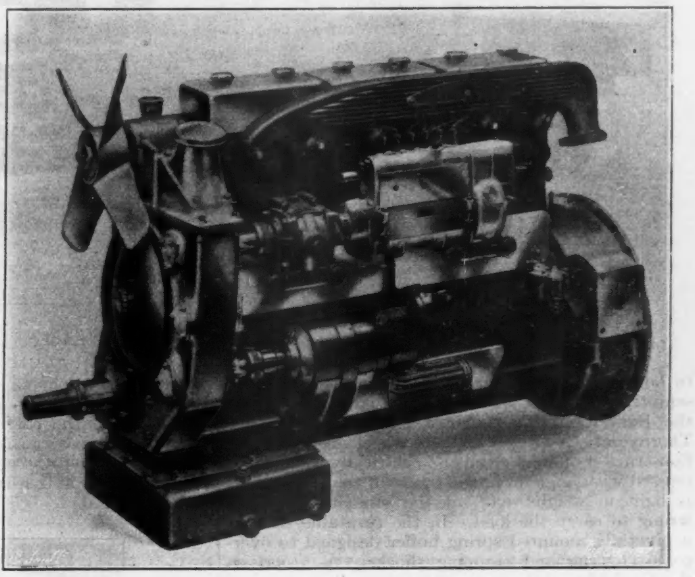

FIG 14—140 B.H.P. 6-CYLINDER OIL ENGINE—TANGYE

The V R 6 engine operates on the Crossley-Ricardo swirl chamber injection principle, and has a designed output of 62 B.H.P. at 1000 r.p.m., and 100 B.H.P. at 1700 r.p.m., with a cylinder bore of $4\frac{7}{16}$in. and a stroke of 6in. Its R.A.C. rating is 47·3 H.P., and its capacity is 556·7 cubic inches, or 9120 c.cm. All the auxiliary units are attached on the near side of the engine, the off side being reserved for the exhaust and inlet manifolds and the starting motor. As indicated in our illustration, Fig. 12, the cylinder heads are made in groups of three, and are bolted to a cast iron cylinder block which rests on the aluminium alloy crank case, this carrying in turn special cylinder liners made of close-grained air-hardened metal. Steel connecting-rods are employed with aluminium alloy pistons, and the crank shaft is fitted with a torsional oscillation damper. The engine is governed for maximum and minimum speeds, but is so arranged that the hand control is not effected within this range. The full load fuel consumption is about 0·47 lb. per B.H.P.-hour, and the average brake mean effective pressure is nearly 90 lb. per square inch. The economy and reliability of the Crossley oil engine in a large number of goods and passenger vehicles has led, we learn, to many conversions from petrol engine operation being made.

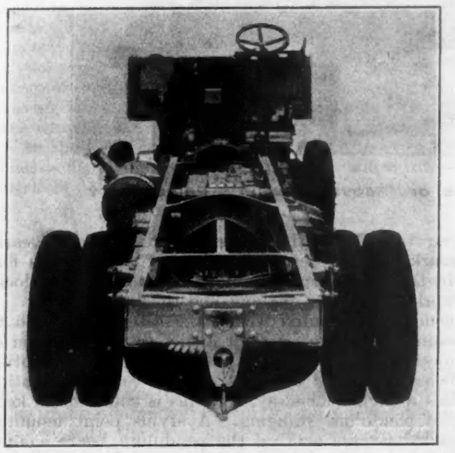

FIG 13—REAR VIEW OF "BETA" CHASSIS—CROSSLEY

Ransomes, Sims and Jefferies, Ltd.

Two electric trolley omnibuses of the latest design are shown by Ransomes, Sims and Jefferies, of Ipswich. One is a four-wheel, double-decker for the Ipswich Corporation, and the other a six-wheel, double-decker for Huddersfield. The chassis for the four-wheel vehicle, which is designed for regeneration, is shown in Fig. 15. The control gear is combined with the air-operated foot brakes, so that regenerative braking automatically takes place when the mechanical brakes are applied. In this way maximum regeneration is secured, resulting in reduced current consumption and increased life of the mechanical brake wearing parts. A small foot pedal resembling that of a petrol motor car serves for operating the controller. Of the twelve speeds obtainable eight are economical speeds which can be used without waste in resistances. Both vehicles are fitted with the makers' own traction compound-wound, enclosed ventilated motors, designed in accordance with the British Standard Specification and rated at 80 horse-power in each case. The ratio of horse-power to pounds weight is 1 : 11·2, which represents a considerable advance in this direction. It has been obtained by special attention to ventilation, the use of light-weight alloys, and by taking advantage of electric welding. Although the motor is placed under the saloon, and a short drive is thereby obtained, the height of the saloon from the ground is not increased.

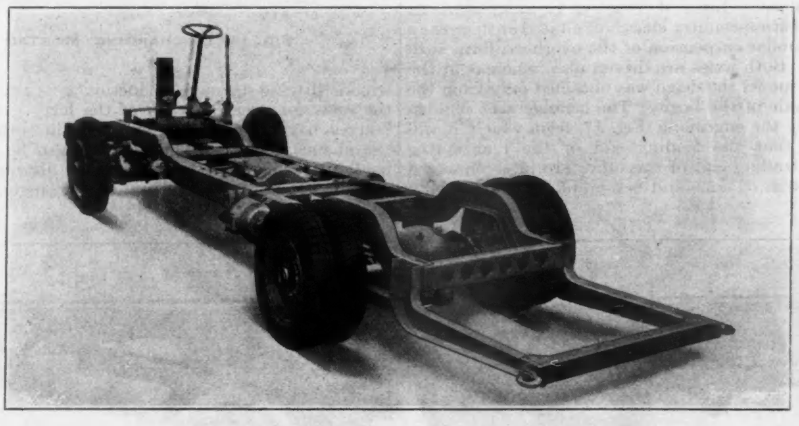

FIG. 15—FOUR-WHEEL REGENERATIVE TROLLEY BUS CHASSIS—RANSOMES, SIMS AND JEFFERIES

On both vehicles the transmission takes the form of a Ransomes-Garrett patented tubular telescopic propeller shaft and universal joint.

A noteworthy feature of the six-wheel vehicle is the provision of a third differential, which ensures that the drive on both rear axles is equalised at all times, irrespective of the tire diameters. Wheel slip is, therefore, eliminated and tire wear reduced.

As regards the design of the bogie, all torque rod reactions are neutralised, thereby counteracting the tendency for different pressures to occur on the two axles, during acceleration or braking. Another feature of the six-wheel vehicle is the patented cam brake gear, which ensures that the total braking area on all the brake drums is utilised when the service brake is brought into use. As compared with the service rendered by the orthodox system, this arrangement is said to have increased the life of the friction linings to a remarkable degree.

Another exhibit on Ransomes, Sims and Jefferies' stand is a new electric truck with a low-loading elevating platform. Simplicity is the outstanding feature of the design, and it is impossible for the platform to over-run in either direction. Damage to the mechanism is thus eliminated. Although the truck is designed to carry a load of 2 tons, it has a large reserve of power, and on test it took its full load up a gradient of 1 in 5.

Tangyes Ltd.

The firm of Tangyes Ltd., of Cornwall Works, Birmingham, is showing a full range of garage equipment and generating and power plant, including a 7-ton hydraulic lift for commercial vehicles. This is shown in operation with a Daimler commercial chassis equipped with a Tangye heavy oil engine. Both the four and the six-cylinder engines are also exhibited on the stand, and we have chosen the latter unit for illustration in Fig. 14. It operates on the "Omo" combustion principle, which, it may be recalled, incorporates a hot body with an oblique passage connecting to the cylinder space. A complete description of the combustion process, and typical performance results, were given in The Engineer of October 16th, 1931. The Tangye engine has been designed to conform with the best British commercial vehicle practice, and to give easy access to all working parts. As our illustration shows, the cylinder heads are cast in pairs. They are made of a special nickel iron, and are secured to an aluminium alloy cylinder block and crank case carrying the centrifugally cast cylinder liners in water jackets. The pistons are die cast and are of the Nelson-Bohnalite type, with four pressure rings and one oil scraper ring. The connecting-rods are of nickel steel with white metalled bottom ends, and a hardened and ground crank shaft is employed. The auxiliaries and lubricating arrangements conform to standard practice, special features being that the auxiliary drives are all enclosed and are mounted on the near side of the engine. The engine operates with a lubricating oil pressure of about 60 lb. per square inch.

The engine we have described has a designed output of 120 B.H.P. at 1800 r.p.m. and 140 maximum at 2000 r.p.m. Its capacity is 9·2 litres or 0·566 cubic inch, corresponding to a high output of 15·9 B.H.P. per litre. It weighs with the starter 1350 lb. and has an R.A.C. rating of 45·9 H.P. A feature is the low injection pressure of 1400 lb. per square inch, with an idling steady speed of 275 r.p.m. The fuel consumption is 0·4 to 0·45 lb. over a speed range from 1400 to 2000 r.p.m.

The Eagle Engineering Company, Ltd.

The new legislation for the regulation and taxation of heavy motor vehicles is bringing into greater prominence the possibilities of trailers and semi-trailers, and considerable interest, therefore, attaches to the stands of all the firms exhibiting such products. On the stand of the Eagle Engineering Company, Ltd., of Warwick, a wide range of such vehicles is to be seen, and we illustrate in Fig. 16 a 4/5-ton semi-trailer similar to the one actually shown. At the Exhibition this trailer is shown coupled to a Thornycroft A E/F B 4 12ft. wheel base chassis. Constructed of steel channels, electrically welded and trussed with angle iron, the frame of the attachment is light in weight, and, at the same time, amply strong to carry the load. In the turntable there is a pivotally mounted spring buffer designed to overcome starting and stopping shocks. As usual on these vehicles, there is a quick lifting device worked by means of curved racks and machine-cut pinions. Some of the most interesting trailers made by the firm are for use with the Scammell "Mechanical Horse." A special 6-ton hydraulic end-tip trailer of this type has a body of all-steel construction, 14ft. long by 7ft. wide by 1ft. 6in. deep, and the tipping gear is of the telescopic underslung ram type. The pump and tank units are mounted on the tractor. It is interesting to learn that the Eagle Engineering Company, Ltd., has come to a working agreement with Scammell Lorries, Ltd., to manufacture tipping trailers and municipal equipment for use in conjunction with the latter firm's mechanical horse.

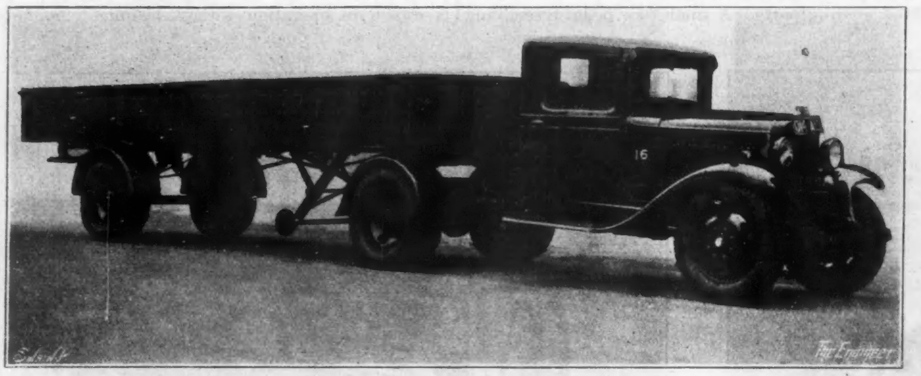

FIG. 16—4/5-TON SEMI-TRAILER—EAGLE

Garner Motors, Ltd.

In connection with the last biennial Commercial Motor Transport Exhibition we described and illustrated a method of underslung suspension for the two rear axles of a six-wheeled lorry devised by Garner Motors, Ltd., of Tyseley, Birmingham. In the 4 WD cross-country chassis exhibited at this year's show a similar suspension of the overhead form is to be seen. Both axles are driven also, whereas in the previous model the drive was obtained only from the leading axle of the bogie. The arrangement is illustrated by the engraving Fig. 17, from which it will be seen that the leading end of the rear spring and the trailing end of the other are interconnected by a system of links and bell-crank levers in such a way that the load is shared equally between the two wheels even on a very bumpy road. The drive and braking torque is taken by the springs. It should also be noticed that the axles are mounted offset on the springs in order that long easy riding springs may be fitted in spite of the short bogie centre distance. Other advantages of the arrangement are that the movement of the compensating mechanism for a given rise and fall is reduced, while the different periodicities of the two sides of each spring tend to prevent or damp out wheel bounce. In order to relieve the springs of the twisting strains caused by the large criss-cross articulation that may occur in cross-country work, swivelling spring eyes are introduced into the design at each end of each spring.

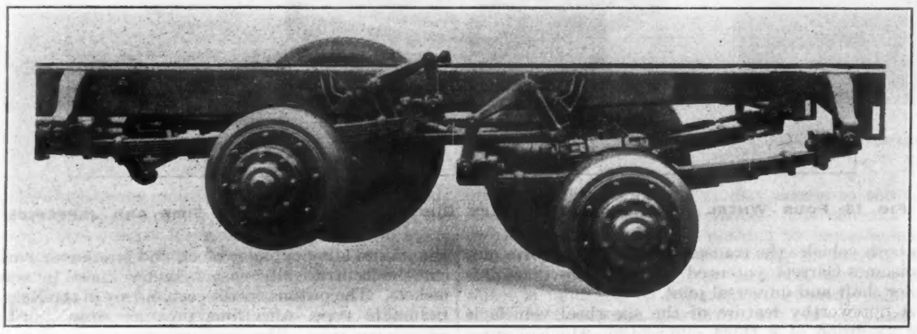

FIG. 17—OVERHEAD SUSPENSION SYSTEM FOR BOGIE OF SIX-WHEELER—GARNER

Several chassis and lorries of different types are shown by these makers, ranging from the 2½-ton 4 WD we have already mentioned to the TW 60 4-ton rigid six-wheeled forward control chassis.

Principality Wagon Company, Ltd.

On the stand of the Principality Wagon Company, Ltd., of Cardiff, a 5 cubic yard body, 13ft. by 6ft. by 2ft. 8in., is shown mounted in a "Thornycroft" J J chassis. The Principality body has a moving floor mounted upon rollers. The engraving reproduced in Fig. 18 shows the device in use. It is particularly adaptable for the carriage of such loads as mortar, road-making materials, coal, bricks, &c. In action, as will be seen from the engraving, the driver or one of the workmen winds a handle at the back of the body, which, driving through reduction gearing, delivers the material over the back of the lorry. Since the body is never tilted, no unequal strain is thrown on the chassis. The mechanism may also be used for loading. Where the haulage and distribution of road materials is concerned, the arrangement has the advantage that small dumps of road repair materials may be made at frequent intervals along the roadside with very little bother. The actual floor is made of rubber cotton duck belt, and the makers state that a case has been brought to their notice in which a Ford chassis had conveyed over 30,000 tons of coal with very little deterioration of the moving floor. Besides the Thornycroft chassis, the company is also exhibiting a 6-ton Eagle trailer equipped with the Principality flat-platform body, and another exhibit is an "either-side" discharge moving floor specialising in the conveyance of tarmacadam and road material in general.

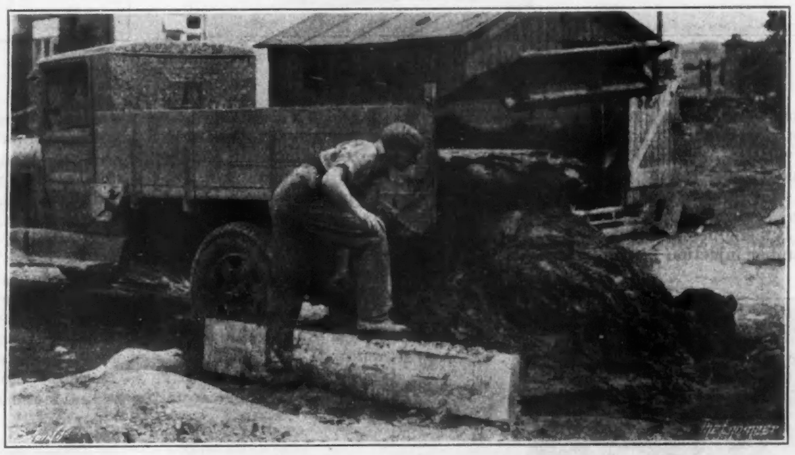

FIG. 18—DISCHARGING MORTAR BY MEANS OF "MOVING FLOOR"—PRINCIPALITY

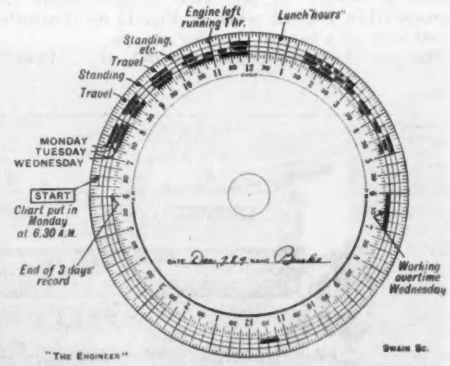
Servis Recorders, Ltd.

Turning away for a while from actual vehicles and engines, we found on one of the stands in the gallery an ingenious and, at the same time, very simple instrument which automatically marks on a chart the exact time a vehicle is actually moving, the periods for which it is standing, and whether, in the latter condition, the engine is idling and shut off. The instrument is made by Servis Recorders, Ltd., of 72–75, Red Lion-street, London, and is particularly useful to road transport operators as a check upon their drivers and the actual use made of the vehicle on the road. Several varieties of instrument are made suitable for one-day, three-day, or eight-day charts. A three-day chart is reproduced in the drawing, Fig. 19. It will be seen that it is circular, and that 12 noon is placed at "12" on a clock face, and 12 midnight in a position corresponding to "6" with the intermediate times clearly marked. The actual diameter of the chart is 6in. In the instrument this chart is rotated by a clockwork mechanism making one revolution a day. A pendulum mounted within the case is arranged to swing in a plane at right angles to the direction of motion of the vehicle, its maximum degree of motion being controlled by stops. Every vehicle in motion has a slight side-sway, and this is sufficient to keep the pendulum swinging. A stylus point mounted on a suitable arm on the pendulum bears against the face of the chart, which, red in colour, is covered by a thin coating of wax. This wax is scraped off by the stylus, leaving the "red" of the chart face standing out in relief. Arrangements are made by a simple mechanism by which the stylus is caused to trace a spiral record on charts that last for more than one day. In the chart reproduced the times of running and standing are clearly marked. It will be observed that the driver never spent less than 1½ hours over his lunch, and that on Monday he finished his afternoon's work at 3 p.m., but did not come "home" till 5. On Wednesday, he worked overtime from 6 to 7 p.m., and for some reason the vehicle was used on Tuesday night. On Monday, between half-past ten and half-past eleven in the morning, the fact that the engine was left running although the vehicle was standing, is shown by a thickening of the line. This thickening of the line is caused by a slight "trembling" of the pendulum.



"THE ENGINEER" SWAIN Sc.

FIG. 19—CHART FROM SERVIS RECORDER

The working parts of the instrument are enclosed within a metal container about 7in. in diameter for the larger charts, such as that illustrated. This case is screwed on to the back of the cab above the driver's head. It is made in two halves hinged together with a "snap" lock opened by a key of the Yale type. The case is opened for the insertion of the chart and the winding of the clockwork motor every day, every third day, or every seventh day, according to the type of instrument installed.

THE A.E.C. AND ENGLISH ELECTRIC COMPANY, LTD.

In conjunction with the Associated Equipment Company, Ltd., the English Electric Company is showing the four-wheel double-deck trolley omnibus, illustrated in Fig. 20. It provides seating accommodation for sixty-three passengers, and is said to be the first vehicle of the kind to have such a carrying capacity. The body and equipment were made at the Preston and Bradford works of the latter firm, and the chassis at the Southall works of the A.E.C. The double-deck coach built body seats thirty passengers in the lower saloon and thirty-three in the upper compartment, the essential difference between this vehicle and other four-wheel double-deck vehicles being that the entrance is next to the driver and abreast of the front wheel. The rear part is entirely enclosed, and is utilised for seating accommodation. Apart from the fact that the arrangement provides nearly 20 per cent. increase in the number of seats, it simplifies the work of the driver and conductor. While the former has the exit and entrance of passengers directly under his observation, and is therefore able to start and stop the vehicle without having to wait for signals, the latter is able to devote the whole of his time to the collection of fares.

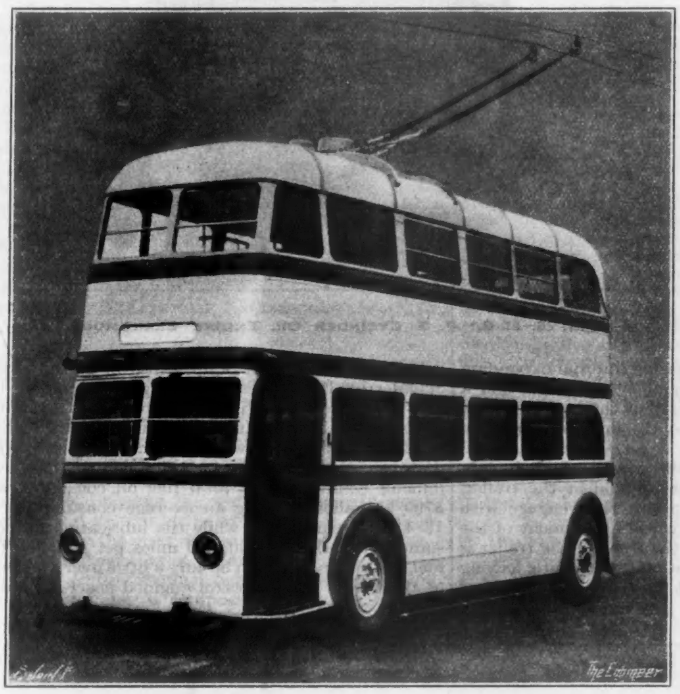


FIG. 20—DOUBLE-DECK TROLLEY BUS—A.E.C.-E.E.C.

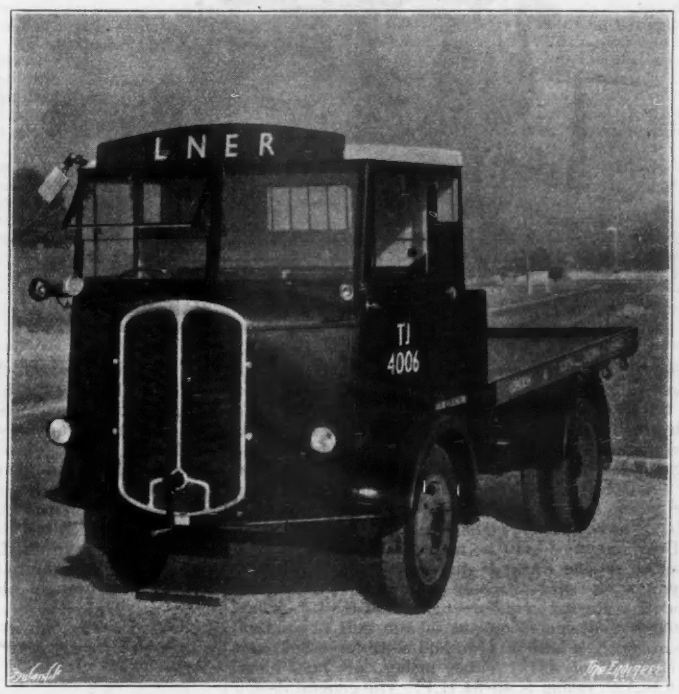

FIG. 22—2-TON HANDY PLATFORM LORRY—THORNYCROFT

As shown in the table of dimensions the two axle chassis has a wheel base of 15ft. 10in., and a turning circle of 54ft.

Chassis Dimensions.

Wheel base	15ft. 10in.
Wheel track, front	6ft. 4¾in.
rear	6ft. 6in.
Overall length	25ft. 8½in.
Overall width	7ft. 5½in.
Frame height, laden	1ft. 10in.
Turning circle	54ft.
Weight complete	3 tons 3 cwt.

Both front and rear wheels are fitted with 20in. by 11·25in. tires of the low-pressure balloon type. The frame is composed of 11in. by 3in. pressed channel section with the front end of the near side member downswept to facilitate low loading, while the cross members are of the tubular type.

Hydraulic shock absorbers are fitted to the springs, and interchangeable shackle pins are provided. The rear axle is of the fully floating variety. Chassis lubrication is reduced to a minimum by the use of roller bearings on the brake cam shafts and cross-shafts. Braking on all wheels is provided by the Lockheed air-assisted system, and is applied by means of a foot pedal. A 3/8 H.P. motor-driven compressor unit fixed to the side frame of the chassis by means of "Silentbloc" suspension, provides the compressed air. The hand brake operates independent shoes on the rear wheel. A spotlight at the rear of the vehicle is actuated automatically from the brake pedal.

All the electrical equipment is mounted on the frame, and the self-ventilated English Electric motor situated in the middle of the chassis and mounted cantilever fashion on the off side of the frame, drives the rear axle directly by means of a single cardan shaft fitted with large Spicer couplings. The arrangement greatly improves the accessibility of the motor, allows the provision of a low floor and assists weight distribution. Weatherproof and splashproof cases fixed to the chassis side frame house the contactors. Rustless and jointless unbreakable grid resistances are also mounted on the chassis framework from which they are well insulated.

The master controller, the reverser, trolley skate, change-over switch, terminal board, and stop light switch are mounted in a case under the driver's seat, and the controller is operated by means of an organ type foot pedal. Cab tire 660-volt sheathed cable is used throughout, and the body can be removed from the chassis while leaving all cables, with the exception of the trolley cabling, intact, the latter being disconnected at the terminal board. The entire equipment was tested at 3000 volts A.C. at the English Electric Company's works.

JOHN I. THORNYCROFT AND CO., LTD.

One of the largest exhibits on the stand of John I. Thornycroft, Ltd., of Basingstoke and London, is the new "Stag" 12-ton insulated box van, illustrated in Fig. 21, which is one of an order for forty similar vehicles recently placed with the firm by the Metropolitan Transport Supply Company. The engine is one of the Thornycroft six-cylinder 99 B.H.P. petrol models, with a bore of 4⅜in., a stroke of 5¼in., and an R.A.C. rating of 45·9 H.P. It operates in combination with a dry-plate clutch, and a four-speed gear-box, with an auxiliary gear-box operated by a separate lever and giving an additional range of exceptionally low gear ratios.

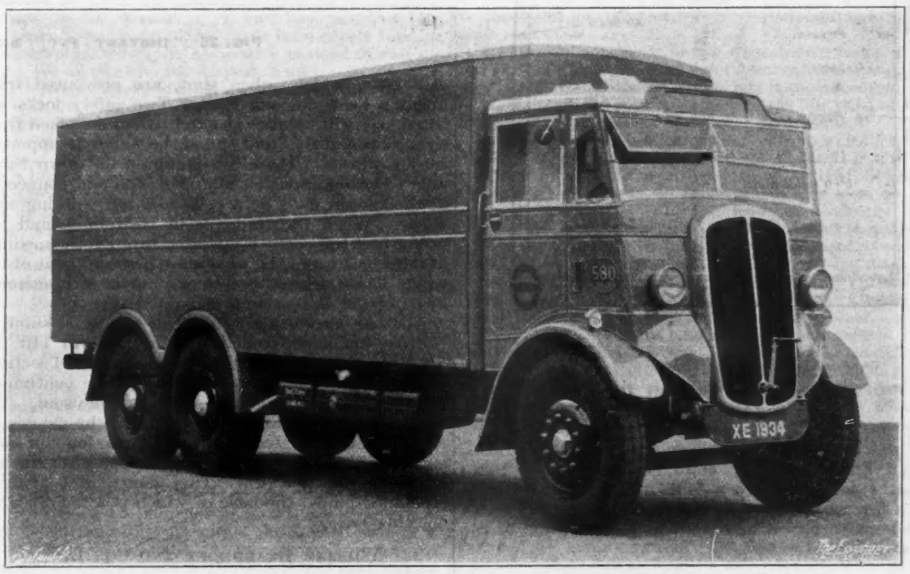

FIG. 21—"STAG" INSULATED 12-TON BOX VAN—THORNYCROFT

The main gear ratios are fourth, direct; third 1·52; second, 2·40; first, 4·50, and reverse, 5·50. The weight of the standard chassis with 42in. by 9in. straight-sided pneumatic tires on the front axle and 13·50in. by 20in. low-pressure pneumatic tires on the bogie axles, complete with auxiliaries, is 11,844 lb., which, together with a body allowance of 3700 lb., totals 15,544 lb. In Fig. 24 we show a section through the body of the van, giving the principal dimensions. Features in the design include the use of easily replaceable Masonite Tempered Preswood panels giving unusual strength for heavy service. In order to prevent the twisting of the body in service, a reinforcement of steel cross bracing has been employed, which gives a structure free from oscillation and body movement. There are two rear doors and a side door, and an important feature is the provision of air spaces in the sides and top of the body, with a view to equalising the temperature in the interior of the van in different weather conditions. By means of suitably arranged Beclawatt metal louvres at the top of the van and bottom openings, a free flow of air from bottom to top and from front to rear is obtained. The body is, as shown in the drawing, secured to the chassis by means of U bolts on stirrup brackets fitted to the cross bearers. The front end of the body is left clear of the chassis side members in order to allow for the flexing of the chassis. A particularly comfortable and neatly planned driver's cabin has been provided, with forward control and triple-servo brakes, acting on all six wheels.

Another interesting vehicle is the new "Handy" 2-ton platform lorry illustrated in Fig. 22, which is one of an order for thirty-one vehicles for the London and North-Eastern Railway. With a wheel base of only 9ft., the turning circle is approximately

37ft., while the unladen weight of the complete vehicle is only 2 tons 6 cwt. 1 qr. The power unit is a 40 B.H.P., four-cylinder type engine, with a 3¾in. bore and a 5in. stroke, and a Treasury rating of 22·5 H.P.; weight of chassis with cab, 1 ton 17 cwt., track 5ft. 7½in. There are forward controls and a forward engine mounting, and the rear axle is of the spiral bevel full-floating type, with a power-assisted foot brake acting on all four wheels. The tires are 32in. by 6in. truck pattern, with twin tires on the rear axle. A feature of the design is a driver's cab which, while providing a neat lay-out of controls and a single step, greatly assisting the ease of mounting and dismounting, can, by the removal of four bolts, be lifted from the vehicle in six minutes, leaving the engine and front axle ready for inspection. The cab can be replaced in eight minutes.

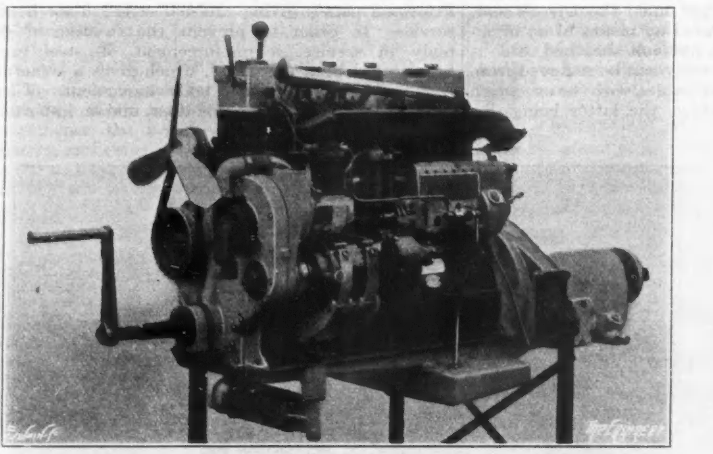

FIG. 23—100 B.H.P. 6-CYLINDER OIL ENGINE—THORNYCROFT

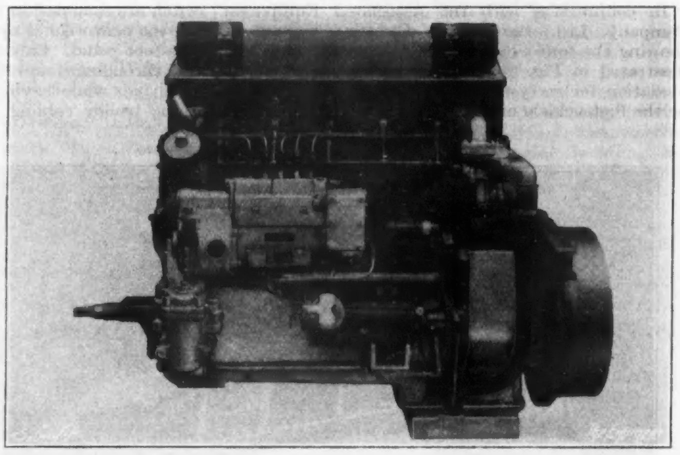

FIG. 26—85 B.H.P. 5-CYLINDER OIL ENGINE—BEARDMORE

Brief reference may be made to the new Thornycroft oil engine which is shown for the first time at Olympia in the form of six and four-cylinder models. The six-cylinder engine, illustrated in Fig. 23, has a designed output of 100 B.H.P. at 1800 r.p.m., with a bore of 4⅛in. and a stroke of 6in., and a capacity of 481·1 cubic inches, or 7880 c.cm. The R.A.C. rating is 40·84 H.P. The general design is very neat, and on the test bench at Basingstoke we were able to inspect the engine running under load very quietly and with a clear and odourless exhaust. As our illustration shows, it is complete with a unit construction gear-box, providing four forward speeds and one reverse, the top gear being the direct drive. Remote control change-speed gear is provided, the hand lever working in an oil-tight box bolted to the crank case of the engine. The gear ratios are: Fourth, direct; third, 1·52; second, 2·40; first, 4·48, and reverse, 5·48. When in the course of a few weeks the new engine has completed trials, we hope to give a more extended description of the new design.

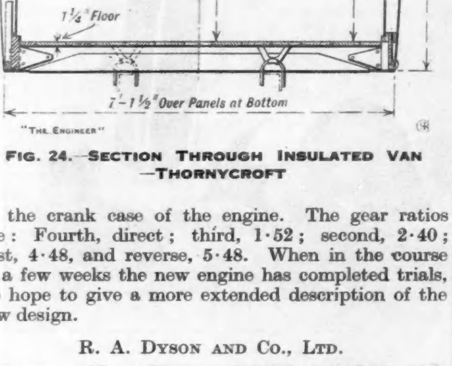

FIG. 24.—SECTION THROUGH INSULATED VAN —THORNYCROFT

R. A. DYSON AND CO., LTD.

The firm of R. A. Dyson and Co., Ltd., of Liverpool, is one of those which has early come to the conclusion that experimental work is necessary to see by how much the tare weight of its productions may be reduced, and we understand that the company is now busily engaged upon testing metals and forms of construction, which, though light, will give a generous overload safety factor. At the Exhibition the firm has concentrated upon the showing of popular types of trailer rather than those for special services, which are only of interest to the limited few faced by the particular problems concerned. One of the most interesting exhibits is the "Instant-Fit" six-wheeler attachment for 2-ton chassis. It is capable of carrying loads of 4 to 5 tons and is illustrated in Fig. 25. The chassis is built up of rolled steel channel sections, reinforced with flat mild steel strainers. The centre king posts, the bases of which are fitted in the centre cross member, are adjustable, and in this manner the slight initial stretch of the strainer bars can be taken up. Double-acting self-energising internal-expanding brakes in drums 16in. in diameter are fitted, and a feature of the arrangement is that the brake bracket and axle block are cast neatly integral with one another.

To attach the trailer to the power unit it is only necessary to back the latter up against the trailer. Lifting ramps on the power unit then engage with inclined guides on the fifth wheel attachment of the trailer, with the result that the front of the trailer is automatically lifted into position. Automatic locking in position is brought about by two hinged jaws of cast steel, which, when shut, are prevented from opening by a machined pin. Two safety locks are fitted. It will be observed that when detached from the power unit the front end of the trailer is supported by leg wheels. These are mounted on down tubes able to swing about their upper ends and connected at their lower ends by a yoke to a nut working on a screw. When the trailer is in position behind the power unit this screw is operated through the medium of mitre gears and the wheels are drawn up out of the way. These wheels are steerable, the arrangement being of the Ackerman centre point type.

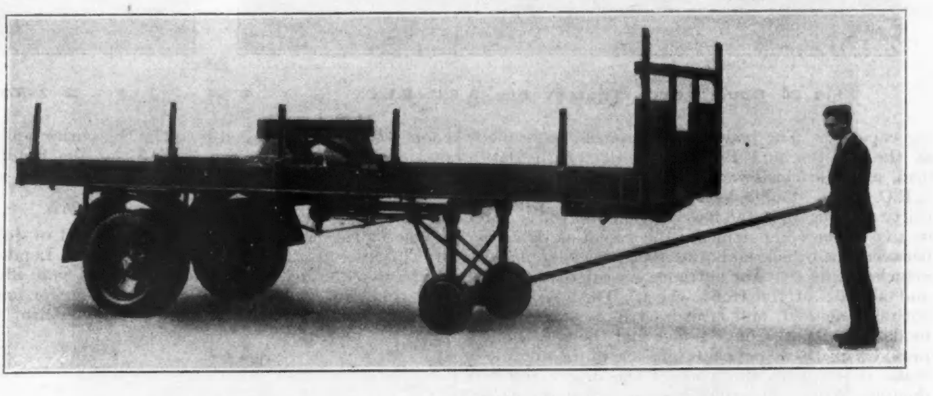

FIG. 25—"INSTANT-FIT" SIX-WHEELER ATTACHMENT—DYSON

Another interesting vehicle on the same stand is the 5–6-ton super-trailer, with a platform 14ft. by 7ft. It is constructed of rolled steel channel sections welded at the four corners to form one continuous frame. The suspension is somewhat unusual. The front end of each spring is secured to the chassis by means of a cast steel shoe. The rear end of each spring is also fitted with a shoe, the base of which is of a dovetail pattern. This shoe slides along a machined guide, the base of which is a reciprocal of the shoe base.

WILLIAM BEARDMORE AND CO., LTD.

A complete range of Beardmore high-speed heavy oil engines is displayed on the gallery stand of William Beardmore and Co., Ltd., of Dalmuir, and 36, Victoria-street, London. It includes four, five, and six-cylinder engines with a cylinder bore of 4¼in. and a stroke of 6in., giving at 2000 r.p.m. designed outputs of 65, 85, and 100 B.H.P. respectively. The weights of these engines, including the starter motor dynamo and brake exhauster, are 1160 lb., 1290 lb., and 1450 lb. for the three models in the order named above. In the accompanying illustration, Fig. 26, we show the five-cylinder model, which has an R.A.C. rating of 36·1 H.P. and is governed at 2250 r.p.m. It is a fly-wheel type unit arranged for hand starting. The performance results are illustrated in Fig. 27. In connection with the Olympia Show, Messrs. Beardmore have arranged to have available as demonstration vehicles several commercial vehicles which have been on the road for a considerable time. Among the vehicles available for demonstration purposes we may mention a large Albion vehicle and also Leyland vehicles, of which two examples may be given. A six-cylinder 100 B.H.P. Beardmore engine was installed in a 32-seater Leyland "Tiger" omnibus with a maximum designed speed of 50 miles per hour. Up till April a total of 50,796 miles was covered in 177 operating days, giving an average of 287 miles per day over difficult country. The total fuel oil consumed was 3790·75 gallons, giving an average consumption of 13·4 miles per gallon, while the lubricating oil consumption worked out at 650 miles per gallon. The fuel costs were shown to be only a little over a seventh of those of a similar petrol engined coach. Similar figures are available for a Leyland "Bull" forward-driven goods-carrying chassis which has now covered over 30,000 miles with an average consumption between 13 and 14 miles per gallon of oil fuel and a lubricating oil consumption of about 1000 miles per gallon.

Another interesting exhibit on the stand is a new 45 B.H.P. engine with a bore of 3½in. and a stroke of 5in., designed to operate at 2400 r.p.m., which will further extend the range of the Beardmore high-speed oil engine.

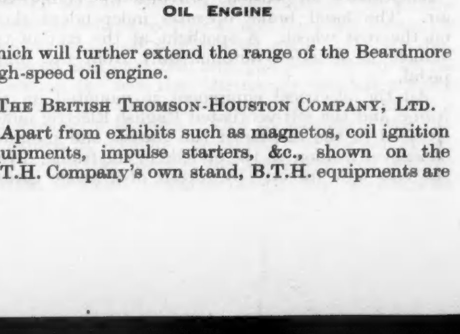

FIG. 27.—PERFORMANCE CURVES OF BEARDMORE OIL ENGINE

THE BRITISH THOMSON-HOUSTON COMPANY, LTD.

Apart from exhibits such as magnetos, coil ignition equipments, impulse starters, &c., shown on the B.T.H. Company's own stand, B.T.H. equipments are fitted to trolley omnibuses exhibited on other stands.

The contactor panels of these regenerative control equipments are mounted in the driver's cab. The shunt field contactors are fixed to the front dash, and as they open and close against rubber buffers they are practically noiseless. Simple control is made possible by a B.T.H. patented gearless controller, which requires a very light pressure to operate it. A short drive serves for transmitting the power to the back axle from the compact and lightweight motor, which is mounted under the floor of the vehicle, and is, therefore, very accessible. The shunt field resistance is composed of vitreous enamel tubes mounted on a frame with a louvred cover, whilst the main resistances, which are of the rustless unbreakable type, are mounted at the side of the chassis. While dirt and moisture cannot reach the resistances from below, a free passage is allowed from the front to ensure adequate ventilation. On a Karrier vehicle with B.T.H. field regulated equipment, the series field of the motor is divided into six stages by means of three contactors, which first close singly, then two simultaneously, and finally all together.

The master controller is fitted with a side-operated pedal with a patented internally expanding brake and a release spring, arranged so that when the driver tilts the pedal slightly backwards a locking action takes place, thus keeping the controller pedal steady in any desired position without effort, whilst the act of easing the foot pressure leaves the pedal free to return to the " off " position.

The Brush Electrical Engineering Company, Ltd.

A single-deck, long-distance, 32-seater coach, mounted on a Daimler chassis with a six-cylinder poppet valve engine and Daimler fluid fly-wheel transmission, incorporating a four-speed pre-selective self-changing gear-box, is shown by the Brush Electrical Engineering Company, Ltd., of Loughborough. The wheel base is 17ft. $\frac{3}{16}$in., the overall length 27ft. 1in., and the width 7ft. 6in. In regard to shape and contour at the front and rear, the vehicle is designed on the most modern lines, and incorporates such features as chariot pillars in the front, special belt rails, *de luxe* seating, lighting, and ventilation. The main framing is composed of selected oak and English ash, in combination with flitches and gussets to pillars, crossbars, and other members. The entrance is at the rear, where there is a sliding door, whilst an emergency exit with a hinged door is provided on the offside at the front. A hinged emergency light, with a sliding window, is provided on the near side of the driver's cab. The well type floor is covered with linoleum, whilst special rubber matting is used for the centre gangway. A single panel sliding " sunsallon " head is fitted to the roof, and is panelled on the undersides in Alhambrinal. Container racks inside the vehicle, and adjacent to the ceiling, lockers under the floors with doors to give access from the outside, and a boot built up as part of the roof outside at the rear, provide ample accommodation for luggage. Half drop windows of the Widney-Stuart latest type are fitted with louvres on the outside, whilst patented ventilators fitted with mirrors are provided at the front end.

The Brush Company is also exhibiting a double-deck, low-height, 56-seater, service omnibus body, mounted on a Leyland T D 3 chassis, equipped with a six-cylinder petrol engine, improved clutch, simplified brake gear, and a full floating axle.

(To be continued.)

Poplar is generally known as a perishable wood, difficult to dry; this is, in a sense, true. In the green condition poplar may easily become infected with fungi, with consequent rotting of the wood; this is particularly true of the sapwood. The exercise of certain precautions in the interval between the felling of the tree and the conversion of the log into lumber will prevent infection. By the observance of good drying practices the manufactured lumber may be seasoned without much loss through degrade caused by either rot or twisting and warping.

Speaking at the twelfth annual dinner of the Institution of Engineers (India), the Hon. M. E. A. H. Blunt said :—" My only venture in the engineering line has been the building of certain tanks. . . . They were very good tanks, and they held quite a lot of water, but unfortunately most of them also held a crocodile, which rather cramped the style of the villagers who wanted to use them. A real engineer, of course, would doubtless have devised some method for letting water in whilst keeping the crocodile out. This was beyond my engineering skill, but I rectified my error subsequently by shooting the crocodile. In addition to this solitary feat of mine, I can claim at the present moment to be very closely associated with one of our two great engineering departments, namely, irrigation. And I find that association as interesting as it is pleasant. Occasionally, too, it inspires me with awe, for instance, when I receive a report full of such terms as kilowatt, ampère, or volt. In such circumstances I have so far found the dictionary not particularly illuminating. So far as I can make out, the position is that when one Italian scientist called Volta carries one French scientist called Ampère against the resistance of one German scientist called Ohm, the result, more or less, is one English engineer called Watt. That, of course, is interesting knowledge, and I am pleased to possess it, but I have not yet discovered what use I can make of it."

Cast Iron Research Association.

On Wednesday, November 1st, Major F. A. Freeth, F.R.S., of Imperial Chemical Industries, took the chair at the annual luncheon of the Cast Iron Research Association, and delivered the short Presidential Address, from which the following passages have been taken :—

Unlike the great organisation with which my predecessor in office, Sir Harold Hartley, is connected, my company cannot claim to be a large producer of ferrous castings. It is, however, a very large user. Our needs cover a wide range of material and are met by a number of foundries. Since much of this material has to withstand special conditions with respect to corrosion, erosion, heat and mechanical stress, we look to the Cast Iron Research Association for the progress which makes possible the production of cast irons more capable of withstanding these conditions. We believe that it is the duty of all founders to support this Association, and hence put themselves in a position to carry out these developments as and when opportunity offers. We have made large-scale tests of some of the Association's developments, such as Silal and Nicrosilal heat-resisting irons, and we look forward to further opportunities of doing this as other discoveries are evolved. One of these is referred to in a guarded manner in the report, as in member's own interests I do not propose to particularise, but it offers promise of producing a standard type of cast iron which can act as a basis or datum for various methods which have been evolved for securing a high-quality material. These processes include desulphurisation, degasification, alloy additions of various kinds, together with the process of inoculation by means of which the 30-ton iron has now arrived at commercial production. This is a state of affairs upon which the industry and the Association can be warmly congratulated. As is hinted in the report, the process cannot yet be applied to the whole range of production, particularly to large castings, and in some castings of widely varying sections it may be undesirable to use it at all. While the designer endeavours to make the sections of any casting as uniform as possible, and to arrange changes in section to be as gradual as possible, the possibility of securing these different sections in one piece forms the very *raison d'être* of the casting itself.

You have doubtless all heard of the recent development which is being sponsored by my company, Imperial Chemical Industries, Ltd., for the production of oil from coal. The importance of this cannot be over-estimated, for the importation of foreign produced petrol is one of the most considerable individual factors in our adverse trade balance. The production of home-made petrol, practicable on account of our coal supplies, is not only of vast industrial importance, but it may be on occasion vital to our national security. We are making it our business to see that in the materials employed in the new plant, the fullest possible advantage is being taken of modern metallurgical knowledge.

I do not propose to say anything in detail about the work of the year because this is available in the annual report itself. I will content myself with observing that the Research Committee, in framing the programme, has had regard to every important aspect which enters into the production of the products with which you are concerned, and with adding that greater resources in equipment and staff would enable the programme to be both speeded up and extended.

I said on a previous occasion that the Association ought to have an induction melting furnace, even if it meant that the Council should go dog racing to raise the money ! It is not fitting that industry, which resignedly pays taxes and rates to put up the buildings and equipment for our universities and technical schools, should deny essentials to the body which is likely to have such a profound effect on its capacity to pay those rates and taxes in future. I learned, as I am sure you also learned, with particular pleasure of the generosity of our Vice-president. Mr. H. James Yates, in providing funds for a cupola furnace, an essential for which the Association has had to wait too long. We all owe him our deepest thanks.

My reference above to a datum reminds me that I must deal with the question of finance. The Cast Iron Research Association does not enjoy an overdraft at the bank. It is solvent, and all its equipment and apparatus, as you see from the balance sheets, stands at *nil* in the books. But it has no reserves and at any given time has less than a month's normal expenditure in hand. You are aware that up to June, 1931, ten years after our establishment, the work of the Association was made possible by a Government grant of £1 for £1 on industrial subscriptions. The Government has always insisted that Research Associations should be financed by means of regular subscriptions rather than by means of sporadic donations or payments for work actually done, because more than any other kind of human activity, research must be done steadily and without break in its continuity. This can only be provided on the subscription basis. It can, as I have indicated, be greatly assisted by appropriate apparatus and equipment and suitable accommodation and working conditions, but it depends primarily on the functioning of the grey matter in the mind of the investigator, and if the work is to be done properly he has to be protected reasonably from interruption. Now we have never in the Cast Iron Research Association considered direct contact with members in the industry as an interruption in this sense. The programme is designed to meet what the Council believes to be the needs of the industry, and the contact between the staff and members is a perpetual source of fresh inspiration as to what these needs are, apart from the opportunities it offers of applying what has already been learnt. This apart, I repeat that the investigator works most fruitfully when he works under the best conditions.

I have been engaged the whole of my working life in research, often research of a very abstract character, and from my later experience in encouraging and inspiring researchers. I want to tell you how very sympathetic we have to be towards them. I know no job which holds so many disappointments and discouragements. The business man, whether he be engaged in selling, in manufacture, or in purchasing, has his disappointments, but he stands on reasonably firm ground. He knows where he is. In pushing out, however, into the unknown, the research man is faced with a succession of disappointments ; just as walking may be described as a succession of interrupted falls, so research progress must largely consist in properly learning from failure. The process is almost impossible to describe, and, incidentally, almost equally impossible to organise. The investigator is so often dealing with the intangible. When a research problem can be reduced to the point at which a perfectly clear and definite programme can be laid down to a given end, the problem as such has practically ceased to exist. It has, in a sense, been solved because the path has been visualised, and all that remains is to proceed to the more or less anticipated conclusion. Before this, however, we have to go through a process which can only be described as getting a " hunch " or idea ; an experiment is tried to see if the idea works, and, if so, how far ; generally it does not ; sometimes it does, but not quite in the way it was expected. The idea has to be modified and a fresh experiment tried, and so the process goes on until a reasonably clear conception of what is happening in a given set of circumstances is evolved. When this conception has been fully formulated, it is necessary to try further experiments to see now whether the idea will work exactly as anticipated, in which case the conception stands verified. During the year the following up of one such train of thought in the laboratories involved two members of the staff in something like 900 individual melts of material. I want to lay stress on the necessity for persistence in reaching the conclusion, in spite of the discouragements that may have been felt, say, at melt No. 200 or melt No. 500.

Research is essentially exploration, for which the investigator has to fashion his own specially sensitive and delicate mental instruments. It is like trying to reach the centre of a maze, which can sometimes be found by a happy accident, or by sheer good luck, like drawing a horse in the Irish sweep, none the less welcome because it is so thoroughly deserved, but it is most assured when the side tracks which so often appear to be the main path are systematically explored and labelled for future use so as to prevent confusion. It is sometimes like trying to unravel a particularly tangled thread. You try to release a knot here and fail and you have to go to another and try that, and suddenly, after many efforts, the whole thing unravels almost miraculously if you have resisted the temptation to cut what may appear to be a loss.

The next difficulty occurs in putting the idea into practice, and cases are well known in which this industrial development has taken many years. Twenty or thirty years is by no means uncommon, and when the Association's heat-resisting irons were evolved one member ruefully remarked that they had only just settled down to manufacture on the basis of a discovery that was at that date over twenty years old. One of the great advantages of the research association movement has been to diminish this period, in which years have been reduced to months. The development stage, however, equally provides its problems no less difficult in their way than the original research and involving both expenditure and time. The troubles here arise from four main causes. The first is the larger scale on which the work is done ; the margins which suffice for laboratory work have to be increased in an ordinary production process for it to be mistake-proof. The mere change in scale also introduces complications. Secondly, the requirements of an individual works are in many respects peculiar to itself and the original process requires to be modified to suit. Thirdly, on the laboratory scale, for the purpose of making progress at all, it is necessary to simplify the procedure as much as possible. In work on an industrial scale, and particularly in this extremely complex material, many variables come in which have not been allowed for in the original work, and which change from application to application, and these have to be taken into account. Finally, there are the differences in the capacity of various works, which show themselves, for example, in the fact that one works can undertake a development and carry it through quite successfully, whereas another works meets with difficulties, either of *personnel* or of equipment or control. There may be successful manufacture but inadequate selling, or *vice versâ*, and so on.

A successful conclusion at this stage demonstrates what was once said by a very successful American scientist, that the " equilibrium between mental and material conception is so sensitive that anything which to the fair mind seems possible is to the trained persistence permissible."

Reverting to the question of finance, from which I have digressed, the Association enjoyed the £1 for £1 grant for the last few years of the ten-year period, to 1931, because the Council undertook, in times which now seem to us relatively prosperous, to raise from the industry for succeeding years an income of £10,000 in order to qualify for a grant of £5000. Had the money been raised, it could have been very well expended, but the depression made it impossible and we are indebted to the Advisory Council for their consideration in modifying the arrangement into which the Council in all good faith had entered. The necessity for economy, furthermore, compelled the Government to reduce the grant offered from the maximum of £5000 to a maximum of £3000. During 1931–32 and 1932–33 this grant was earned by raising from the industry the stipulated amounts, respectively £6250 and £6500. The two years' breathing space expired last June, at the beginning of this financial year, but even at this date the possibility of raising the datum of £5000 plus £3000 in order to earn £3000 in grant is beyond immediate possibility, and the Advisory Council has for the current year and next year fixed the datum at £4000, so that the Association must raise £7000 in the current year and next year to earn £3000 of grant. For every £1 short of that sum £1 of grant will be lost. I understand that the estimated income for the current year is of the order of £6700, and we therefore are anxious to make this £7000, so that the programme can be maintained. In the hope and anticipation that this will be done, the Council has decided not to curtail the present programme and we look to the industry to make up the amount required. If we can get more, we shall have a good case for asking that the grant maximum be increased, and we shall not be content until our present income is doubled. We all owe our warmest thanks to the Advisory Council and the Department of Scientific and Industrial Research for their consideration and help throughout.

One of my predecessors, Sir Philip Nash, in 1929 quoted an estimate from the annual report that year of the value of the output of this industry considered as castings, the figure being one approaching 40 millions sterling per annum in a normal year. Since this estimate was formulated the Census of Production figures for 1930 have been published and the output figure for the industry is given, incidentally for the first time, as nearly 26 millions. Bearing in mind the fact that the Census admittedly does not include all establishments, and also the difference between 1930 and a normal year, the estimate is very satisfactory. There is no estimate for the corresponding Census in 1924 for foundries, but the figures exist for the iron and steel trades as a whole and assuming that the drop in output is similar in the two cases, in 1924 the value may be taken as 37·5 millions, without taking any account of those establishments not covered by the Census. I think you will agree that the estimate is very close indeed. I believe that an industry whose products are valued at figures of this order both requires and is able adequately to support a national research organisation such as we represent.

I wish to say a word with reference to the success recently of the latest attempt we have made to increase the area of contact between the staff and the members. This was the study course held in October. The numbers greatly exceeded anticipations, and I have had an opportunity of reading a number of letters from members who were represented, expressing their satisfaction with the course in the most enthusiastic terms and making it clear beyond any doubt that similar provision in future at appropriate intervals would be welcomed. The preparation for this course entailed a large amount of work from the staff and the results greatly exceeded expectations.

I would conclude by saying that Sir Harold Hartley's period of office has ended on a note which must give you all satisfaction. The financial difficulties caused by the fall in grant will, during the coming year, I think, be entirely overcome, and with the grant situation stabilised for two years we can look forward to a period of uninterrupted progress. Anything I and your Council can do to promote that will be done.

South African Engineering Notes.

(By our South African Correspondent.)

Industrial Output.

According to Union statistics, the value of the industrial output in 1929–30 was £113,000,000, as compared with £45,500,000 obtained from the gold mines. The industries paid wages amounting to £27,500,000, as against £14,943,000 paid out by the mines. The industries bought £27,000,000 of South African goods, as compared with £9,600,000 worth bought by the gold mines. In making comparisons between the mining activities of the Union and those of the other industries—"secondary" industries—it has to be borne in mind though that it is the mining industry that has brought the population to the country that has, in turn, brought these industries into being. Some interesting facts have just been obtained with regard to the industrial expansion during the last four years, which are also very surprising in view of the fact that the period referred to has been one of serious depression; 23,602 more people, including 12,352 Europeans, are now employed in South Africa as the result of 557 new factories having been set in operation in the last four years, and the erection of more factories is contemplated. The South African factories are paying out £4,457,621 more in wages than four years ago, and South African industrial concerns—excluding the mines—are now spending £8,179,696 more in purchasing raw materials, and the value of the goods turned out is no less than £17,996,830 more. Modern methods are employed in all factories of repute, and expense is not spared in installing the latest machinery. Workmanship has been improving year by year, as experience has been gained. Of course, as the figures show, many of the new factories are small and only deserve the name of factory because of the definition of factory in the Acts. Among new factories which are either in course of construction or shortly to be proceeded with are the following:—A match factory at Germiston, a welding electrode plant at Durban, an oil seed crushing plant in Johannesburg, a knitted underwear manufactory at Johannesburg, and a large grape juice factory near Cape Town. There are to be three new footwear factories. Barkers (Britain) are to make men's footwear at Cape Town, and two big factories are to manufacture canvas shoes. One of these is to turn out 2,000,000 pairs per annum. Large capital is being invested in a factory to make champagne at Paarl. A big Netherlands firm has decided to make worsted and clothing materials in Johannesburg; another manufacturer is to make helmets there, and yet another a silk-finishing factory. On the Umgeni River, near Durban, a paper-making industry is to be established. The factory is to cost £300,000, and will produce a minimum of 15,000 tons of paper from 45,000 tons of "bagasse"—a waste residue of the cane after sucrose extraction is complete.

Johannesburg's Traffic System.

According to a resolution passed by the Johannesburg City Council, London's traffic chief (Lord Ashfield) will appoint an oversea expert to act as chairman of the Commission of Inquiry into the city's transport system. The University of Witwatersrand and the Electricity Supply Commission have been asked to appoint the other members. Elaborate figures have been prepared to show Lord Ashfield how Johannesburg's transport system works. It has been a formidable task for the administrative staff. It is intended to show what system is in force in a city of 205,400 Europeans where each individual takes an average of 449·57 rides a year, and the tram routes cover 51 miles and the omnibuses 38·6 miles. The statement shows that the capital expenditure on the trams is £1,412,268, and on the omnibuses £128,783. Almost 1000 men are employed by the Department, and the wage paid is about £250,000 a year for the uniformed staff alone. During 1932 the Council ran a fleet of 210 trams and 56 omnibuses. The joint loss of the trams and omnibuses for the year ended June 30th, 1933, it is estimated, will be £79,000. These particulars are supplied to Lord Ashfield to enable him to arrive at a decision as to the type of man required to act as chairman of the Commission.

Faster Mailboat Service.

A mild agitation is proceeding in favour of obtaining a faster mail service. At present the Union-Castle liners carrying the mail between London and South African ports take sixteen days and twelve hours. To reduce this time by one day, as suggested, would mean, if the sailing times were retained as at present, that the mailboat would arrive at Cape Town on a Sunday, a difficult day for working and involving the incurring of heavy overtime charges. If this was avoided by starting the voyages earlier, there would still remain the extra expenditure on coal. To reduce the time by one day would mean an increase in speed of 1 knot. In the case of mailboats such as the "Arundel" and "Windsor Castle," this would mean an additional consumption of coal of 1100 tons on the outward voyage, and a corresponding amount on the homeward voyage, or 2200 tons more. It is also pointed out that the earnings obtained by the company from the East and West Coasts will now be greatly reduced by the subsidy now agreed to be given to foreign lines to run steamships to serve those coasts already well served by the existing British and foreign lines. It is true that the speed of the mailboats under the present contracts is little greater than thirty years ago, but there is no real demand for quicker passages, either on the part of the passengers or exporters, except, perhaps, in the case of shipments of fruit to England. All things considered it does not seem that the shipping company can be reasonably asked for additional services, or for a reduction in freight charges and passenger fares, as is also suggested, unless, of course, the Union Government is prepared to increase the subsidy. As the Government has decided to give £150,000 a year to Italian lines for almost nothing, it should be able to offer the Union-Castle Company a liberal increase for the additional speed mentioned.

Goods Traffic Jump.

Goods traffic earnings on the railways reached the highest figures for any one week during the past 2½ years in the week ended September 16th. The total earnings during the week were approximately £80,000 better than the total for the corresponding week of 1932. During the week ended September 23rd, both Cape Town and Durban harbours broke all weekly tonnage records for the past three years. Over 35,700 tons of cargo were landed at Durban and over 30,000 tons at Cape Town. With the object of increasing trade with the East, the Union Government has appointed a Trade Commissioner, who will be stationed at Batavia.

Wages in Gold Industry.

The great increase in the profits of the gold mines, consequent on the big rise in the price of gold since the Union went off the gold standard, which has resulted in the gold mines making a profit for the first nine months of 1933 of £22,549,236, compared with £10,889,736 for the corresponding period in 1932, has resulted in the miners putting in a demand for a share in the excess profits. The men's unions have just put forward a request for a 20 per cent. advance in wages, and for a working week of forty hours instead of forty-eight, as at present. The Chamber of Mines is considering the demands. Some concessions will probably be made.

The Analysis of Coal and Coke.

A Fuel Research Survey paper, No. 29, by Dr. H. V. A. Briscoe, Dr. J. H. Jones, and Dr. C. B. Marson (deceased), dealing with an investigation into the accuracy of routine analytical determinations on coal and coke, has just been published by the Department of Scientific and Industrial Research.* Most of the results were obtained from investigations carried out jointly at Newcastle-upon-Tyne by the staff of the Department's Coal Survey Laboratory and the staff of the Northern Coke Research Committee. The paper points out that accuracy in sampling and in analysing coal and coke is of very great importance, although, from the nature of the substances dealt with, it is very difficult of attainment. The question is by no means of academic interest only. Coal is a highly complex substance, which, in chemical and physical characteristics, ranges through almost endless variety. This is now recognised in industry, where modern conditions and processes demand a high efficiency, only to be achieved, in the case of coal, by careful selection of the coal used. For this reason, the classification of coal, originally an academic investigation, is now of considerable interest to industrialists. This classification, however, is almost wholly based on chemical data, and the question of the reliability of the data becomes important.

Further, it is now generally recognised that the only satisfactory basis on which coal can be bought and sold is partly its chemical constitution, and, more especially, its heat-giving power, as determined in the laboratory. In the case of metallurgical coke, on which the iron and steel industry depends, the requirements of the consumer are equally explicit, although tending more to the physical nature of the material than to its chemical composition.

The reliance to be placed on the data obtained in the laboratory depends to a larger degree, however, on the accuracy of sampling. When it is realised that the sampling of coal and coke is in itself a very difficult question, it will be seen that the whole problem moves in a vicious circle, for we can only judge the accuracy of sampling by comparing results of chemical analysis, and our judgment of the accuracy of chemical analysis is dependent on the degree of accuracy in sampling.

The present paper forms an important contribution to this subject, for, in the work which it describes, the accuracy of the analytical results alone, free from the complication of sampling, has been considered on a mathematical basis, with the result that it is now possible to judge the accuracy of routine analytical work, and, in addition, to obtain a clearer view of other aspects of the problem, viz., sampling and the actual methods used in analysis.

In the work on coal, sampling errors were reduced to a minimum. A single block, about 16 lb. weight, was crushed, mixed and divided by coning and quartering into sixty-four small samples. These were subjected to routine laboratory determination. The results were then tabulated and examined in the light of the mathematical principle known as the Law of Errors. The mathematical formulæ used are given and the results obtained are tabulated in detail at the end of the report.

Routine determinations on coke were dealt with in a similar way, one representative sample being divided into sixty-four laboratory samples on which repeat determinations were carried out.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

ROAD TRAFFIC SIGNALS.

505—1933. The Departmental Committee on Traffic Signs, which was appointed by the Minister of Transport in December, 1931, requested the British Standards Institution this year to make recommendations for a standard form of specification for the equipment of light signals and to consider the following matters:—(1) The laying down of standards including standards of colour with which optical systems of signals should comply; (2) the specification of the type of beam to be employed; (3) how far it was practical and desirable to require that all types of flexible progressive installations should be capable of being interconnected. The British Standards Institution has accordingly drawn up this specification. It first of all defines the terms used, *e.g.*, signal, signal head assembly, &c., and then, under the heading "Optical Requirements," deals with the distribution of light, the direction of the beam, the arrangement of the optical systems, the green arrow, the colorimetric properties and the transmittance of the glass, the visor, and the height of the signal. The actual construction of the signal, the control requirements, such as the time of the cycle, and the sequence and duration of the aspects, the master, local and isolated controllers, and the control construction are dealt with in separate sections and there is a miscellaneous section covering such items as elimination of surges in the co-ordinating circuit, radio interference, external finish, interconnecting cables, and the use of plant leased from the G.P.O. The last section deals with the tests necessary for compliance with the specification. One of the seven appendices indicates a type of apparatus which may be used for preventing electrical interference with radio transmissions caused by the operation of the signals.

CATALOGUES.

Siemens Bros. and Co., Ltd., Woolwich, S.E.18.—Catalogue 150 on paper-insulated cables.

Gummers, Ltd., Rotherham.—Catalogue section "E" of the "Twintite" plunger valve.

Rose, Downs and Thompson, Ltd., Old Foundry, Hull.—List 15 on vegetable oil refining plant.

Davy Bros., Ltd., Park Ironworks, Sheffield.—Publication 63 on filter presses, dryers, and mixers.

Thos. Firth and John Brown, Ltd., Sheffield.—A publication on steels specially resistant to corrosion.

Elliott Bros. (London), Ltd., Century Works, Lewisham, S.E.13.—Publication 811 on the "Tolemache" bin level indicator.

Imports Duties Advisory Committee.—The Import Duties Advisory Committee gives notice of an application for a redution in the import duty on magnet coils wound with aluminium wire adapted for use in electric hoists and separators.

London Iron and Steel Exchange.—The annual dinner of the London Iron and Steel Exchange will be held on January 30th at Claridge's Hotel, Brook-street, W.1. Colonel D. J. Colville, Minister for the Department of Overseas Trade, has accepted an invitation to attend. A number of persons prominent in the iron and steel trades will also be present.

Lantern Slides.—Edward Bennis and Co., Ltd., desire us to say that they have a large number of lantern slides dealing with mechanical stokers and mechanical coal and ash-handling plant, which they will be pleased to lend to societies, institutions or individuals for lecture purposes. Particulars of these are given in a printed booklet which will be sent free to any of our readers on request.

Engineers' German Circle.—There was a good attendance at the Institution of Mechanical Engineers on Monday evening, November 6th, for the second paper of the session, which was read by Mr. F. W. Fass, of the Friedrich Krupp Grusonwerk A.G., of Magdeburg-Buckau, who took as his subject "New Developments in the Design of Cold Rolling Mills, with Special Reference to the Manufacture of Tin Strip." The paper was illustrated with lantern slides. In introducing his subject, Mr. Fass stated that there had been a recent welcome increase in the German tin-plate industry, and he illustrated his paper with descriptions of typical American and German hot and cold rolling mills for mild steel strip. The installations dealt with included typical hot strip rolling plants and Steckel cold rolling mills, with descaling and coiling machines. Some of the more recent developments in rolling mill design were then dealt with in detail and a description was finally given of the modern annealing methods. Typical lay-outs for a modern plant for the annual production of 50 to 70,000 tons of tin strip were shown, with alternative arrangements of four-high rolling mills and Steckel mills, while a particularly interesting mill was a 59in. wide four-high mill with a patented feeding machine for the production of steel sheets for motor vehicle bodies. A short discussion followed the paper, and after the meeting members adjourned to the Anglo-German Club for supper.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Pig Iron Market.

The market for pig iron in this country is strengthening, and one of the features of the position is that buyers who placed contracts some weeks ago for forward delivery up to the end of the year are now showing a disposition to buy for delivery in the spring and are also increasing the quantities they are taking against their old contracts. The general demand has improved, and business with those consumers who as a rule buy from hand to mouth is developing along satisfactory lines. The position on the North-East Coast is especially sound. Scottish consumers, as well as local buyers, are taking good quantities, and although no official figures have been issued regarding the tonnage now in stock in makers' hands, assertions have been made for some time past that these are not greatly in excess of the normal, allowing for the fact that considerable quantities have already been sold. At the same time, the market would feel happier if an authoritative statement on the position were made. The position in the Midland pig iron market has also become more satisfactory, and although in some quarters it was expected that the Midland producers would raise their prices, at the last meeting their decision to maintain existing rates did not come as a surprise, as in this part of the country stocks have not been depleted to the same extent as those on the North-East Coast. The demand from the light castings trade is active, particularly from that section engaged in producing building material, whilst business in forge iron has also increased during the past few weeks. In Lancashire the demand for pig iron is steadily expanding, although the rate at which consumers are taking deliveries might be improved upon. The condition of the engineering trades in this district is better than for some time, and if this improvement continues there should be a substantial increase in the supplies required. The situation in Scotland is not perhaps so satisfactory as in most of the English districts, and probably the demand is not sufficient to take care of the full production. The hematite market shows a notable change for the better lately. The recent increase in prices has been maintained and good quantities have been sold in the Midlands and South Wales. The export market remains uncontrolled and makers appear anxious to secure business, and seem prepared to accept cheap prices, probably with a view to reducing their stocks, which are still considerable.

Semi-finished Steel.

The cheerful conditions which have prevailed in this market for some time past continue to rule, and, if anything, the situation is improving from the point of view of the producers. The minimum price for British billets has been definitely fixed at £5 5s., although, in fact, this figure had been in operation for several weeks. It is difficult, however, to buy at less than £5 7s. 6d., or to place orders for delivery before the end of this year. For forward sales probably the minimum quotation would be accepted, but there are a number of re-rollers who, for various reasons, find it necessary to place comparatively small orders for near delivery. Naturally, consumers are becoming rather perturbed at the manner in which the market is gaining strength. A number of the more important users have long period arrangements with the producing works, and may not be immediately affected by the position. Others, however, are nervous, not only concerning the tightness of the position, but also regarding the prospects of further increases in price. Under these conditions more business than usual has been placed with Continental makers, although for some time only moderate quantities have been offered on the British market. In particular the tonnage of small billets offered to British consumers has been declining for some time. The advance in prices of British semi-finished steel has been followed by an increase of 2s. 6d. (gold) in the Continental prices, making the basis price for billets, 2in. and up, £5 10s. d/d Birmingham, and £5 d/d other districts, whilst the quotation for sheet bars is now £5. So complete is the Continental control of the importation of billets and sheet bars into the British market under the new Cartel arrangements that it will probably be found that as the British price is advanced so the Continental quotation will be fixed immediately below it. The quotations for British soft, medium, and hard basic billets have been advanced 5s.

Shipbuilding and Current Business.

The new shipbuilding orders which have reached the Scottish and English shipyards, although they do not amount to a revival in this depressed industry, are encouraging, as they indicate that shipping firms are taking a more optimistic view of the position. On the Clyde a contract for a motor liner of 10,500 tons gross and a cargo steamer of 5000 tons d.w. have been placed with Alexander Stephen and Sons, Ltd., of Linthouse. D. and W. Henderson and Co., Ltd., of Partick, have secured an order for a cargo steamer of 5000 tons d.w., and another cargo steamer of similar tonnage has been ordered from Lithgows, Ltd., of Port Glasgow. J. and G. Kincaid and Co., Ltd., of Greenock, are to provide two sets of oil engines for the motor vessel to be built by Alexander Stephen and Sons. At Leith the construction of a twin vessel will immediately follow the launching of a large motor coaster. It is also announced that Vickers-Armstrong, Ltd., have received inquiries for two refrigerator cargo ships. Interest has been aroused by a statement that agents for the Soviet Government are inspecting the British cargo vessels which have been offered for sale, with the intention of acquiring several of them. In South Wales, although no contracts of importance have been announced, the ship-repairing yards have been busy. Business has been active along the Welsh coast, including the yards at Cardiff, Newport, Barry, Penarth, and Swansea. The Department of Overseas Trade announces that the following contracts are open for tender:—Brazil: Viacao Ferrea do Rio Grande do Sul, hinges, steel brushes, to be presented in Rio Grande do Sul by December 14th; South African Railways and Harbours, wrought iron short link chain, $\frac{1}{4}$in. to $1\frac{1}{2}$in. diameter, stud link cable with shackes for mooring, short link chain electrically welded or machine-made quality, for the period from July 1st, 1934, to June 30th, 1935, to be presented in Johannesburg by December 18th; also supplies of bar steel, to be presented by December 4th; Australia, Victorian Government Railways Commissioners, supply and delivery of one set feed-water heater and equipment for application to an A 2 locomotive, to be presented in Melbourne by January 10th, 1934; Posts and Telegraphs Department, supplies of lead-covered telephone cables, to be presented in Melbourne by November 21st.

Scotland, Lancashire, and Yorkshire.

The new shipbuilding orders for the Clyde which were announced last week have created a more cheerful tone in this market, and backed up by an active demand for steel for ship-repairing should improve the position of the Scottish steel works. The general demand for steel materials is on a good scale, although the engineering industry in Scotland has not been well occupied of late. Business in plates seems to have increased slightly, but there is a considerable amount of unemployed plant in this department. The Scottish sheet makers are only moderately employed, and the galvanised section of the trade, in common with the English works, is experiencing a poor demand. The Scottish re-rollers are better off for work than they have been of late, but are losing a considerable amount of business through the competition of English and Continental works. The quotation for re-rolled steel bars is held at £7 5s. d/d, whilst for export the figure is £6 10s. to £6 15s. Active conditions rule in the Lancashire market, and some fair-sized engineering contracts have been booked which will require a good tonnage of steel. Skipworth, Jones and Lomax, Ltd., of Manchester, have secured an order for steelwork for a new bridge for the Salford Corporation, whilst the Blackpool Municipality has ordered a large gasholder from R. and J. Dempster, Ltd., of Elland. Orders for paper-making machinery have also been secured by Chas. Walmsley and Co., Ltd., of Bury. The increase in the price of billets, and the strong demand for small bars, has led to the Lancashire re-rollers advancing their prices to £7 10s., but it remains to be seen if the re-rollers in other districts will follow their example. If not, it seems possible that competition from sources outside the district will develop. In Yorkshire there has been a continued improvement in business in iron and steel materials, the demand for rods for reinforced concrete work being particularly active. Consumers also continue to take good quantities of special and stainless steel, particularly stainless steel sheets. Business in plates in this district, as in other parts of England, has been light for some time, but recently there has been rather more movement in this department.

Ferro-alloys.

Business in the ferro-alloy market has been slightly better during the past week or two; but still leaves a great deal to be desired. Consumers of nearly all ferro-alloys are content to buy on a hand-to-mouth scale, and transactions of importance are rare. The market for tungsten provides an exception to this generalisation. The price of this alloy continues to advance, owing to the Chinese suppliers of wolfram ore resolutely withholding supplies. Whether the Chinese are deliberately engineering a corner, or whether the scarcity is due to the unsettled conditions in China, it is difficult to say, but the general impression is that the Chinese dealers are clever enough to see the possibilities of the situation, and to keep a tight hold on the quantities which come into their hands. A certain amount of ore is coming from other parts of the world, but it is not sufficient to make up for the absence of the normal supplies from the Far East, and the prices for ferro-tungsten and tungsten metal powder have advanced by 6d. per lb. All sales of this alloy are for prompt delivery, as forward business for the time being is out of the question. The demand for ferro-chrome is steady, and prices show a strong tendency to advance. There has been little speculation in the market, and buying has been almost entirely for industrial purposes. The possibility of a rise in the price of ferro-silicon has created some interest in that market, but the amount of buying has not been sufficient to affect the position. Quotations are still £12 10s. for 45 to 50 per cent. and £18 2s. 6d. for 75 per cent. Business in ferro-vanadium has become more active, and the overseas demand has increased. Interest in ferro-manganese also appears to be growing, and there has been a good inquiry of late on export account. Few transactions are reported in ferro-phosphorus, and the quotation is unchanged at £14 10s. On the other hand, the demand for nickel has broadened considerably, and an extensive business has been done with Germany. The price remains unchanged at £230.

Finished Iron.

Progress in the finished iron market is much slower than in many other departments of the iron and steel trades. In the Midlands business, whilst on a rather broader basis than immediately after the holidays, does not increase according to expectations. Usually at this time of the year a brisk demand is experienced by the producers of bar iron; but at present, although the demand for high-class bars is fairly good, the call for Crown bars is not maintained at the rate which characterised the industry in the early part of September. Business in common bar iron also is quiet, and the producers complain of the competition they are experiencing from the cheaper steel bars. Quotations vary considerably and Crown bars are quoted at £8 10s. to £9 10s. Steady conditions rule in the Lancashire bar iron trade, and prices remain unaltered at £9 10s, with Crown bars quoted at £9. The Scottish producers are handicapped by the small weights of the orders they receive.

Copper and Tin.

The prevailing tendency in all the metal markets this week has been for prices to sink to a lower level, owing to the absence of support from consumers. This is particularly noticeable in electrolytic copper. The American producers do not appear to be able to reach agreement with the Customs smelters upon the provisions of the copper "code" and in spite of the currency inflation American users have bought only moderate quantities. As a consequence, whilst American domestic prices were retained at 8 c., the export price dropped back to 7.85 c., which, as the exchange varied, moved between £35 10s. and £36. This week a fair business was transacted. Owing to the instability of the exchange, the American producers have on several occasions quoted in sterling. The world's markets, however, are too much under the influence of the confusion resulting from the latest American monetary policy to provide an outlet for substantial quantities of copper, and so far as the copper market is concerned, the efforts of the American administration to force up prices have had the opposite effect by destroying business confidence. It is reported that the American producers have asked the American Government to purchase 100,000 tons of their stocks, but this seems an unlikely procedure, even for the present American Administration. . . . Tin has been the steadiest of the non-ferrous metals, and it is one in which American purchasers have shown a fair amount of interest. On the other hand, buying by British and Continental consumers has not improved, and so far as the latter are concerned the quantities have been insignificant. The October statistics showed a net reduction in the visible supply of 2050 tons, after allowing for an increase of 680 tons in the carry-over at the Arnheim smelter. American purchases, plus the improvement in the statistical position, have aroused a certain amount of fresh interest in this market, although speculation is not on the scale which might have been expected. The tendency of dealers in this market is to watch events, although the undertone is sound and any decline in prices has been quickly recovered.

Lead and Spelter.

Prices in the lead market have fluctuated within a few shillings. The declaration of 2000 tons of Mexican lead on the market had a somewhat depressing influence towards the end of last week. This lead being foreign metal is subject to a duty, and will therefore go direct into bonded warehouse, where it will remain until it can be shipped to an overseas destination. In the meantime those to whom it was tendered against Metal Exchange contracts were not anxious to take it up, so it was lent forward on a contango of about 7s. 6d. The question is often asked why this foreign lead should be sent to the London market, but so long as the London Metal Exchange is the one market in which the metal can always be sold, foreign lead will be sent here from time to time. In other respects the market has been in a sound position. The sharp advance which followed the decline in prices was due to reports of industrial troubles at the Australian mines, and was not altogether maintained. . . . Dull conditions have ruled in the spelter market, and even the news that the Cartel contemplated reducing output to 45 per cent. and tightening up its regulations against overproduction had little effect upon the position. Declarations of November spelter have resulted in an increase in the contango, but the worst feature of the position is that the industrial demand for the metal seems to have declined. The galvanising industry has been taking small quantities for some weeks, and although it is said that the brass manufacturers have been rather busier of late, this has not been sufficient to create an appearance of activity in the spelter market.

Average Metal Quotations.

The London Metal Exchange official average quotations for October show a decline for the third month in succession, excepting in the case of tin, which registered an increase in the average price for cash tin of £6 11s. 4d. and for three months of £6 10s. 7d. Apart from this the difference between the September and October averages was not large. The average price for cash copper was down by £1 9s. 9d., and of three months by £1 10s. 1d.; whilst the electrolytic copper price was £1 6s. 10d. less than in September. The average lead price showed a variation of only 2s. 7d. for all positions, which is a sufficient indication of the steadiness of the market. In spelter also the movement was comparatively narrow. For shipment in the current month the average quotation for October was 10s. down, whilst for shipment in the third month following it was 8s. 11d. lower, the mean price being 9s. 5d. less than in September. The official average quotations are as follows:—

STANDARD COPPER	Cash	£33	13	$10\frac{31}{44}$
	3 Months	£33	17	$2\frac{41}{44}$

SPELTER	For shipment the current month	£16	6	$2\frac{7}{22}$
	For shipment the third following month	£16	11	$11\frac{19}{22}$
	Mean	£16	9	$1\frac{1}{11}$
	Settlement	£16	6	3

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Monsieur Paul Painleve.

One of the eminent mathematicians of his day, Monsieur Paul Painlevé, who died of heart failure in Paris on Sunday of last week, at the age of seventy years, endowed engineering with mathematical discoveries of value. His interest in mechanics and invention did much to encourage initiative in the ministerial offices he occupied from the time he entered public life. Obtaining a professorship of mathematics at Lille University at the age of twenty-three years, Monsieur Painlevé was appointed Lecturer at the Sorbonne four years later, and was finally Professor at the Ecole Polytechnique. He had already acquired a wide reputation for his works on differential equations. When Wilbur Wright made his experimental flights in France, Monsieur Painlevé was the first to be taken up in a plane as a passenger, and thenceforth he devoted much of his time to aviation and contributed largely to its scientific progress. So convinced was he of the possibilities of aviation that in 1910 he prepared for parliamentary groups in the Chamber of Deputies a full report upon its value for civil purposes and for national defence, and presented a plan of organisation. After the war he was for some time Minister of Air. For his services to science and to the State Monsieur Painlevé was buried with national honours.

Federation of European Engineers.

The National Syndicate of Fascist Engineers has sent invitations to engineering institutions in Europe to appoint representatives to attend a meeting at Rome at the end of this month or the beginning of December to discuss arrangements for the formation of a Federation of European Engineers. Contrary to the similar French proposal, which leaves the final constitution of the Federation to be settled by a Congress representing national groups, the Italians have presented a definite scheme that provides for a Federation of engineers holding first-class degrees, with the reservation that membership may be extended eventually to all persons of scientific and technical attainments. In a word, it appears that the idea is to create an international association, with the engineering profession as a nucleus, for an examination of economic and technical questions affecting capital and labour and social life generally.

Shipbuilding.

The outlook for shipbuilding has been somewhat improved by the distribution of orders under the programme of naval construction, and by the prospect of shipping companies adapting their fleets to more severe conditions of competition. The Messageries Maritimes are sending one of their most successful ships in the Mediterranean service to the Ciotat yard, where it will be lengthened forward by 8·5 m. on lines designed to increase the speed, and the propelling machinery will also be modified. This work will occupy about a year, and if the result is satisfactory, another ship running between France and Egypt will undergo a similar transformation. It is notworthy that the tonnage of ships laid up in French ports was reduced by 94,000 tons during the six weeks ending October 15th, the total at that date being 846,233 tons. No final decision has been come to yet respecting the claim of the insurance companies to recondition the "Atlantique" in a British yard, and the Compagnie Sud-Atlantique is reported to be taking proceedings against them to recover the full amount, while its intention to have a similar ship built in a French yard suggests the anticipation of a verdict of the arbitration court in its favour.

Coal.

The colliery interests are not relinquishing their efforts to induce the Government to adopt the fullest measure of protection for the coal industry. They affirm that the situation is going from bad to worse, and that notwithstanding the approach of winter there is increasing unemployment amongst miners and that about two-thirds of the men work less than forty hours a week. Stocks at the pits are said to be growing larger every month. The Miners' Union and the coalowners are both urging that the quotas of coal imports should be strictly adhered to, and that they should not be supplemented by special licences, as is sometimes the case, for example, with consignments through Atlantic ports. The arrangement entered into by the State for the importation of German coal by way of the Rhine for the benefit of the inland port of Strasbourg encourages this traffic. The mines in the Saar, worked by the State, are in competition with the northern collieries. They are, of course, within the French Customs frontier. French coalowners complain more particularly of the subsidies paid on the export of coal from Germany and Poland. The Belgian Government has imposed a tax of 10 per cent. on imported coal, the product of that tax to be distributed amongst Belgian coalowners as compensation for loss of trade and as a means of enabling them to keep up miners' wages. German importers refuse to pay the tax. In France, the difficulty is that the home collieries produce only about 75 per cent. of the normal consumption, and any excessive protection would inevitably put up the price of coal, which industrial consumers would not tolerate at a time when everything must be done to stem rising costs.

The Dunkirk Lock-out.

For more than a month operations at the port of Dunkirk have been practically suspended by a lock-out of dockers who refuse to work extra time for urgent loading and unloading of ships, and thereby leave the port in an unfavourable situation with respect to other ports where the same disabilities do not exist. This labour trouble has been causing auxiety to harbour authorities for some years past, and as there is no doubt about the character of the dockers' organisation, the authorities feel that they must put an end to a state of things which has been diverting traffic to Antwerp and other foreign ports.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

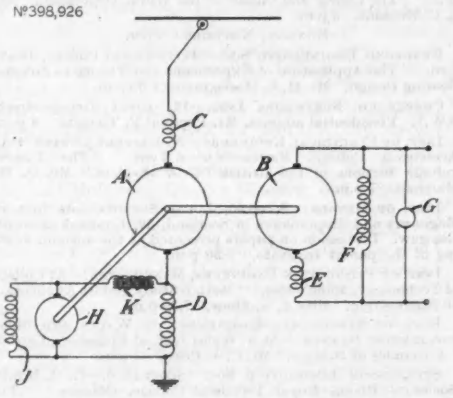
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

DYNAMOS AND MOTORS.

398,926. April 4th, 1932.—Electric Motor Control, Arnold Tustin, of 22, Glentilt-road, Sheffield, and Associated Electrical Industries, Ltd., of Crown House, Aldwych, Westminster.

The object of this invention is to provide improved arrangements for exciting the field of an electric motor so as to obtain approximate constancy of speed when the load on the motor varies and/or when the line voltage varies. A is the armature of the motor and B is the armature of a generator, which is mechanically coupled to the motor. The latter is provided with two series field windings, designated respectively C and D, while the generator is provided with a series field winding E and a shunt field winding F. The motor generator set, thus constituted, may form, for instance, part of the equipment of an electric traction system, the motor of the set being connected by means of a trolley between a line conductor and an earth conductor, and the generator supplying current to a load G connected across the generator terminals. The series field winding D of the motor is connected in circuit with the armature H of an exciter, which is mechanically coupled to the motor and is self-excited by means of the shunt field winding J. The circuit whereby the armature H of the exciter is connected with the series field winding D includes an iron core choke coil K. It is shown that with this arrangement the exciter and choke coil will maintain substantially constant the speed of the motor generator set in spite of variations in load and/or supply voltage.—*September 28th*, 1933.

№398,926

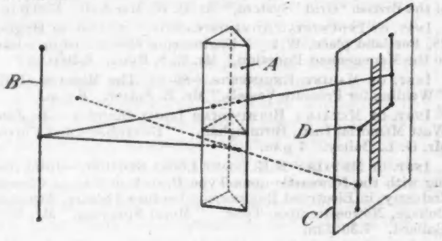


MEASURING AND TESTING INSTRUMENTS.

398,945. April 30th, 1932.—Gauge Glasses, P. E. Drosne, 35 bis rue du Chateau Asnieres (Seine), France, and Union d'Electricite, rue de Messina, Paris.

In this gauge glass advantage is taken of the relative refractive indices of water and steam to show up plainly the water level. The gauge glass A is prismatic and is illuminated by a strip-light B. The image produced on the screen C is shown at D, and emphasises the water line.—*September 28th*, 1933.

№398,945

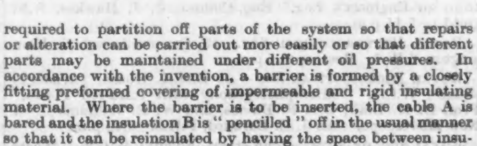


TRANSMISSION OF POWER.

398,920. April 1st, 1932.—Electric Cables, Siemens Brothers and Co., Ltd., of Caxton House, Tothill-street, Westminster, S.W.1, and James Riedl, of 48, Waverley-road, London, S.E.18.

In certain cable systems it may be required to interpose a barrier in the insulation to prevent longitudinal movement of the compound. For instance, in an oil-filled cable system in which channels are provided in the cable, in which oil or compound under pressure is situated and is in communication with the oil or compound in the cable insulation proper, it may be required to partition off parts of the system so that repairs or alteration can be carried out more easily or so that different parts may be maintained under different oil pressures. In accordance with the invention, a barrier is formed by a closely fitting preformed covering of impermeable and rigid insulating material. Where the barrier is to be inserted, the cable A is bared and the insulation B is "pencilled" off in the usual manner so that it can be reinsulated by having the space between insulated parts filled in as at C. The conductor is given a smooth and closed exterior, and is laterally closed against transfer of oil from one section to the other. This may best be effected by cutting the conductor and inserting the cut ends into recesses in a cylindrical metal body D. The insulating barrier E is made, in the first place, of coned shape, so that it is adapted to fit on to the pencilled insulation B. It may continue in cylindrical form F over the remaining insulation—that is, the insulation which has not been pencilled, to and over the covering or lead sheathing of the cable, or, alternatively, the insulating barrier may be continued over these parts and over the conductor in strip form. The space between the joint, when formed, and the joint sleeve is filled with oil or compound as at G. A method of applying the invention to a multi-core cable is also described.—*September 28th*, 1933.

№398,920

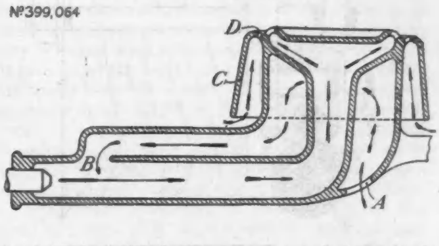


FURNACES.

399,064. January 25th, 1933.—Gas Burners, Gaz and Chaleur, 68, Boulevard Bourdon, Neuilly-sur-Seine (Seine), France.

In this gas burner the primary air for combustion is admitted through the passage A, and is thereby heated to some extent before it is mixed with the gas at B. A secondary supply of air is provided under the hood C, and through the holes D. This supply also is heated by radiation from the flame.—*September 28th*, 1933.

№399,064

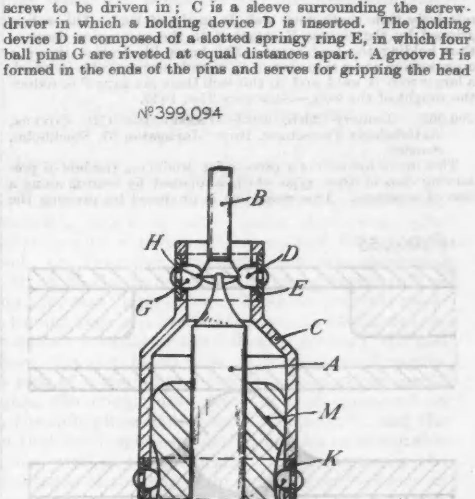


MACHINE TOOLS AND SHOP APPLIANCES.

399,094. February 23rd, 1933.—Screwdrivers, Robert Bosch Aktiengesellschaft, 4, Militärstrasse, Stuttgart, Germany.

A denotes the end of a motor-drive screwdriver; B is the screw to be driven in; C is a sleeve surrounding the screwdriver in which a holding device D is inserted. The holding device D is composed of a slotted springy ring E, in which four ball pins G are riveted at equal distances apart. A groove H is formed in the ends of the pins and serves for gripping the head of the button-headed countersunk screw B. The sleeve C, in which the holding device is mounted, is secured to the screwdriver in such a way that it can be drawn off the screwdriver without the use of tools. It is held by the pins J, which, like the pins G, are riveted to a slotted springy ring K mounted on the sleeve C. The sleeve can be pulled down from the part M by a single pull. When using the screwdriver for other screws, it can then be easily replaced by another sleeve having a holding device adapted to the new screws.—*September 28th*, 1933.

№399,094



398,415. March 1st, 1933.—Making Steel Sections from Discarded Rails, London Works (Barlows), Ltd., Halesowen-street, Oldbury, and A. N. Mayer.

Structural sections rolled from old, worn railway metals have sometimes suffered from the disadvantage that they are liable to be cracked on account of the deformation to which they are subjected in re-rolling. The inventors meet the difficulty by first splitting the heated rail down the centre of

№398.415

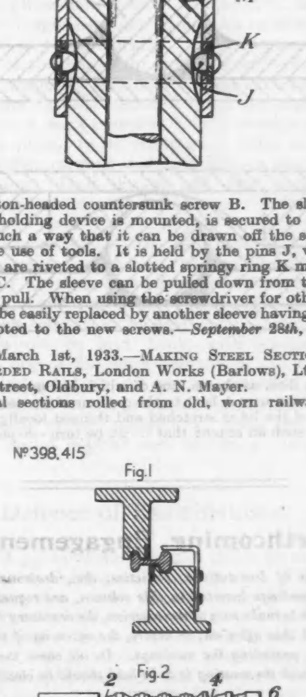


Fig.1

Fig.2

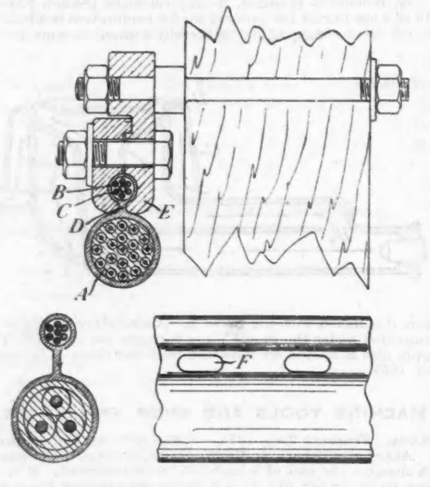
the web, as shown in Fig. 1, and then rolling the two halves, individually, in a series of passes, as shown by the numerals of Fig. 2. For heavy sections the passes 1, 2, 3 are used; for lighter sizes the passes may be either 1, 2, 3, 4, 5, or even include 6 and 7.—*September 14th*, 1933.

MISCELLANEOUS.

398,627. July 19th, 1932.—Electric Cables with Carrying Devices, Lynenwerk, Gesellschaft mit beschränkter Haftung, of Eschweiler, Kreis Aachen, Germany.

The upper illustration shows the invention applied to a multiple telephone cable A, the lead covering of which is connected with the lead covering B of the suspension cable C by means of a relatively thin continuous web D made of lead. The web is gripped by the clamps E attached to the suspension devices, thus holding the lead cover. The lower illustration shows a cross section and a side view of an outside electric cable in which a larger web is used and in this web there are gaps F to reduce the weight of the web.—*September 21st*, 1933.

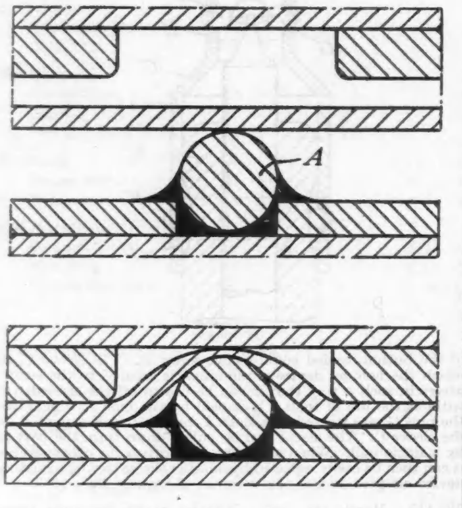
Nº398,627



399,065. January 25th, 1933.—Preserving Can Covers, Aktiebolaget Transitoric, Birger Jarlsgatan 37, Stockholm, Sweden.

This invention covers a process for producing the lids of preserving cans of that type which is opened by tearing along a line of weakness. This weak line is produced by pressing the lid between dies, as shown, one of which has upraised upon it a piece of piano wire A bent to the contour of the tear required. The metal of the lid is stretched and thinned locally in way of the wire to such an extent that it can be torn—*September 28th*, 1933.

Nº399,065



Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

A Seven-Day Journal

◆

Larger Cruisers.

The First Lord of the Admiralty, Sir Bolton Eyres-Monsell, announced in the House of Commons on Tuesday last that the Government had decided with much regret and after mature consideration to modify the 1933 cruiser-building programme, in view of the fact that the British efforts to secure world disarmament and the reduction in the size of warships had not met with the anticipated response by other nations. The programme originally comprised four cruisers, one "Leander" of 7250 tons, and three "Arethusas" of 5400 tons each; the number is now to be reduced to three, the "Leander" being retained and the three "Arethusas" being replaced by two cruisers of a new type, with a displacement of 9000 tons each and larger armament. In making this announcement, the First Lord reminded the House that in 1931 Japan laid down two cruisers of 8500 tons, with fifteen 6in. guns. Her programme includes six ships of this class. The United States, he added, had decided to build four cruisers of 10,000 tons, also armed with fifteen 6in. guns. In 1932 the United Kingdom put forward at Geneva the proposal that future cruisers should be reduced to 7000 tons, with a maximum gun calibre of 6·1in., but the proposal was not adopted. "If, therefore," continued the First Lord, "our programme, already approved, were to be carried out, the new cruisers would be definitely inferior to those being developed by other Powers." Hence the decision to build two large, instead of three small, cruisers, thus keeping within the terms of the London Naval Treaty, and not exceeding the original Estimates.

Encouraging the Use of Steel.

The mission of the British Steelwork Association is to popularise the use of British steel. Hence it was only fitting that the speeches at its annual luncheon should be of a more businesslike character than is usual at similar functions. Mr. Walter Runciman, the Minister for the Board of Trade, took great pains to answer the question many steel makers have asked as to the security they may expect by a prolongation of the present import duties, and whilst denying that he had committed himself, expressed his belief that neither this nor any future Government would remove the present protection afforded the industry. Mr. Ben Walmsley, the chairman, spoke with confidence of the continued improvement in the steel trade, and advocated the greater use of advertisements as an aid to propaganda. He referred to the rivalry between cement and timber and other forms of construction, and pointed out the necessity for an active campaign in favour of the association's own products. He instanced the field that was open to them by the great programmes of slum clearances. Sir Henry Maybury, President of the Institution of Civil Engineers, in responding for the guests, said there were between 6000 and 7000 weak bridges which were unsuitable for the transport of the country, of which he thought reconstruction should be taken in hand. If that were done, it might provide work for some of the unemployed young engineers. Sir William Ray pointed out that much could be done by municipal bodies to stimulate business activity by revising the present Building Acts and bringing them up-to-date and into line with modern requirements.

Rural Electrification Schemes.

According to the thirteenth annual report of the Electricity Commissioners, issued last week, during the year ending March, 1932, transmission and distribution lines were added to the Bedford demonstration rural electrification scheme. The approximate total route length of the overhead and underground transmission and distribution lines provided in the demonstration area at the end of the year was 204·8 miles, inclusive of about 64·2 miles of lines which were erected or laid prior to the official commencement of the scheme. The revenue from the sales of electricity in 1932–33 showed an increase of £4193, or over 29 per cent. on the revenue of the preceding year. It will be remembered that the scheme was put into operation in 1930, and while it has shown a gross surplus in each year the net result after providing for capital charges was a small net surplus in the first year and deficits in the next two years. Results of this character were anticipated, it being recognised that under an intensive programme of development involving both rapid capital expenditure and substantial revenue expenditure on propaganda the scheme would have to bear somewhat heavy charges in the early years which would not be immediately reflected in the amount of revenue received. Some measure of relief was afforded, however, by the suspension of sinking fund payments under consents of the Commissioners in respect of a part of the loans raised for the scheme. As regards the Norwich demonstration scheme, at the end of December, 1932, the high-tension transmission system was practically complete, while at the end of March, 1933, low-tension supplies had been made available to consumers in forty-six out of forty-nine parishes in the area. As in the case of the Bedford scheme, however, that at Norwich was based on a programme of rapid construction and intensive development involving heavy initial charges, and the financial results for the two years' working leave much to be desired.

New Shipbuilding Orders.

At the beginning of the week the Blue Star Line announced that it had decided to place orders in Great Britain for two large ships for the United Kingdom–New Zealand trade, into which it has entered since the signing of the Ottawa Agreements. It will also bring into operation in this trade two other ships, one of 10,000 tons and the other of 9000 tons. At the present time there are under construction in British shipyards several large refrigerated cargo liners which are to be used for New Zealand services. It is anticipated that the new fleet engaged in this trade will have a tonnage close upon 80,000, and that this tonnage, together with reconditioned vessels, will make over 100,000 tons of shipping. Other new orders on the Clyde include a 10,000 gross ton passenger and cargo liner to be built by Alexander Stephen and Co., Ltd., for the Adelaide Steamship Company, Ltd., which will be propelled by twin-screw Kincaid B. & W. type oil engines. Three cargo ships have been ordered on the Clyde by Maclay and McIntyre, Ltd., of Glasgow, one of which will be propelled by the new Stephen three-cylinder compound engine described in The Engineer of October 27th last. Of the other two ships, one will be built and engined by D. and W. Henderson and Co., Ltd., of Partick, and the other will be built by Lithgow's, Ltd., of Port Glasgow, and engined by David Rowan and Co., Ltd., of Glasgow. All three ships will have a deadweight carrying capacity of about 5000 tons each. At Dumbarton, William Denny and Brothers, Ltd., will build an oil-electric ship for David MacBrayne's Portree service, which will be equipped with Davey Paxman G.E.C. machinery. Another announcement recently made is to the effect that the Ailsa Shipbuilding Company, Ltd., of Troon and Ayr, is to build a passenger and cargo steamer for Bristol Channel owners.

Improved Trade Returns.

The official trade returns for the month of October, which have just been issued, show clearly a continuance of Britain's reviving overseas trade. The imports were £66,771,000, representing an increase of £1,004,261 over the figures for October last year. There was also an increase of a little over three million pounds in the imports of raw materials and a small increase in the importation of manufactured foreign goods, which totalled £14,187,000, or only a little over half the figure of £27,249,000 for October, 1931. The export figures were also encouraging, amounting to £38,702,000, which was an increase of four and a-half million pounds compared with last year. The exports of British products amounted to £34,131,000 and increased by £3,691,000, while the sales of British manufactured goods amounted to £26,076,000, showing an increase of nearly £3,400,000. All the leading industries participated in the increase, notably the coal, iron, steel, and non-ferrous metals industries, and also motor cars, chemicals, and machinery manufacture. For the ten months of the present year imports amounted to £549,424,000, equal to a decrease of £31,540,000 compared with last year, while the exports of British produce and merchandise were actually larger, being £302,527,000, as against £301,548,000 in the corresponding ten months of 1932. If re-exports are taken into account, however, there was a small decrease amounting to £165,000 for the month.

The Uses of Coal.

On Wednesday, November 8th, in the course of an address given to the British Road Tar Association in London, Sir David Milne Watson said that national prosperity would return with an extension and a fuller appreciation of the importance of coal carbonisation. Great Britain already produced, he said, 30,000,000 gallons of motor fuel from coal annually, but more than 900,000,000 gallons of refined motor spirit still had to be imported from abroad. In meeting the competition from oil, and in placing coal in a more acceptable and convenient form for the provision of light, power, and heat, the gas and by-product coking industries could, he suggested, act as an indispensable medium of distribution. The gas industry had long been pressing for release from the shackles of obsolete legislation, and he hoped that the day was not far distant when it would be given the opportunity of meeting competition on equal terms. From the coal mine to the carburetter was no idle dream, as the present production of motor fuel from coal proved; again, the increasing use of compressed gas in steel cylinders was an important contribution to the motor transport problem. Referring to the use of British tar, Sir David stated that nearly double the former quantity of home-produced tar was now being utilised on the roads, in the face of keen foreign competition, which was itself a tribute to the lasting qualities of British coal.

Railway Companies' Road Vehicles.

On Thursday last, November 9th, in an address delivered at the Commercial Motor Transport Exhibition, Mr. J. Shearman, the road motor engineer of the London, Midland and Scottish Railway Company, defined some of the requirements of the four group railway companies with regard to road transport vehicles. He emphasised that they were probably different from those of the majority of other operators in that the companies were concerned mainly with delivery services with a limited radius of action, the major portion of the haul being by rail. For the kind of duty under discussion, said Mr. Shearman, ease and cheapness of repair might be more desirable than low first cost or an attractive appearance. A machine which could run, say, 50,000 miles under short mileage and frequent stop conditions without heavy repairs or extensive dismantling would be economical to maintain, even though it might require the overhaul of every unit at the end of that mileage. Synchronisation of the repairs to important parts was the most economical method of maintenance, and in order to ensure that the various parts would require overhaul at the same time, special materials, such as nitrided cast iron and alloy steels, would have to be employed in the case of rapid wearing parts. With regard to the oil engine, Mr. Shearman said that it was early as yet to compare the oil engine with the petrol engine for road transport vehicles, but it seemed possible that its mechanical reliability would be found to be quite as high as that of the best petrol engine.

Oil-Engined Fishing Craft.

The steady increase in the use of British-built oil engines for the propulsion of fishing craft, and the need for the reorganisation of our herring and fishing industries, which is now under discussion, give importance to a review of oil-engined fishing craft which, on Thursday, November 9th, was presented by Mr. A. C. Hardy before the Grimsby Institution of Engineers and Shipbuilders. The slow progress made by the internal combustion engine was attributed by the author to some of the following causes: the bad failure of a ship fitted with an early type of engine, the lack of a simple and easily understood design of engine, the competitive price of coal compared to oil, the difficulties of the trawl winch drive, and the fact that until eighteen months ago the most suitable engines were of foreign origin. After discussing the advantages of the oil engine and the wide choice of design now available, Mr. Hardy sketched the motor trawler of the future. Such a ship, he suggested, might well be a high-powered fishing machine, with refrigerating plant, radio compasses, echo sounder, and all the other modern scientific aids to navigation and to fishing. Hull design had also undergone changes which were shown by the more recent adoption of special hull forms, cruiser sterns, special rudders, and propellers. The trawler of to-day was, Mr. Hardy said, essentially a naval architect's problem, and no mere rule-of-thumb structure. It was generally agreed that large reconstruction programmes must soon be embarked upon, and that the new ships would be laid down with economy of operation as one of the main features of design. An owner who adopted an oil engine-propelled vessel could rest assured, on the grounds of proved economy compared with steam machinery, that he would recover his initial capital cost within a reasonable time.

A Defence of Examinations.

At the first public distribution of prizes at the City of Birmingham Commercial College, on Tuesday, November 7th, Sir Josiah Stamp made a vigorous defence of the examination system. It had been suggested, he said, that men would work just as well without any such incentive, that cramming did no good, and that examinations did not test many of the qualities required in the knowledge of life. In so far as cramming meant that a man had to master the essentials of a subject quickly, and not waste time on non-essentials, it was a very desirable quality for business. Between two men, one of whom was philosophical and the other quick in turning to what was required at the moment, he knew whom he would choose. The examination test, he said, drove men to their full powers, and was a corrective to self-deceit. A certain discipline was wholesome for every human being, and examinations taught the lesson to put the first things first. Subjects were not so much the flowers and the fruit, but the enrichment of the soil from which the flowers and fruit would grow. Sir Josiah paid a tribute to the combined courses of study arranged by the College, its close association with the University, and the facilities it offered for entry into professional life.

Recent Hydro-Electric Power Plants in Sweden.

No. II.

(Concluded from page 451, November 10th.)

VARGON HYDRO-ELECTRIC POWER STATION (*continued*)

The Power Plant.—The low head of water available at Vargön has the effect of making the costs of the civil engineering constructional work relatively high in terms of kilowatts installed. It has, however, been possible to reduce these costs by simplifying the constructional plans. Moreover, the regulating works at Vargön, comprising the barrage and sluice gates, in addition to being necessary accessories to the power plant, directly benefit the Trollhättan and Lilla Edet installations and increase the potential capacity of both of those plants. The features of the Vargön design, which exhibit some departure from the practice hitherto followed in Sweden and result in economy, are chiefly :—(*a*) The two turbine units at present installed are of unusually large dimensions, the runners being 8 m. diameter, as compared with 7·42 m. in the case of the four Kaplan turbines in the Svir plant in Russia, before then the largest in the world ; (*b*) the intakes to the turbines are designed on the syphon principle and it has been possible to dispense with gates ; (*c*) there is no power-house over the generators, which are of the semi-open air type, protected from wind and weather by removable sheet iron covers.

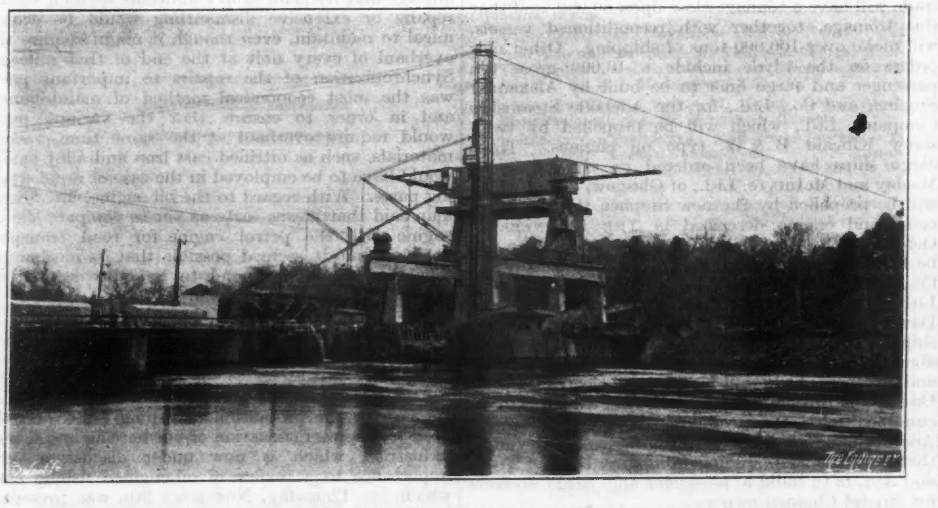

FIG. 15—REGULATING BARRAGE AND POWER STATION FROM UPSTREAM—DECEMBER, 1932

A travelling portal crane of 200 tons lifting capacity—on two hooks—has been constructed to run on rails on the roof of the turbine house. This crane is being used for the erection of the machinery and will be retained for permanent service when required. On each side of the portal is a 6-ton derrick crane, and there is also an auxiliary 10-ton lift on the main travelling winch. The crane has an overhanging roof and screens at the sides, which can be lowered to provide complete protection for the machinery when the cover is removed from a generator for inspection or repair of any of the machinery. The tracks of the portal crane are extended from the power station towards the land on the west side, passing over a small barge basin and storage yard—Fig. 8 (*ante*)—both of which lie within the hoisting range of the crane. The tracks are carried over the basin and yard on a reinforced concrete gantry affording ample headroom—Fig. 15. The barge basin is required because there is no direct connection with any railway. Heavy articles are sent *viâ* Trollhättan, where they are loaded from steamer or railway truck into barges for transport to Vargön. The crane and gantry can also be seen on the left of the view—Fig. 19, page 494.

Constructional Work of the Turbine Pit, &c.—The concrete in the turbine foundations, intakes, &c., including all the reinforced concrete work, contains 375 kilos. cement per cubic metre of concrete. Great care has been taken to ensure an impermeable concrete by suitable grading of the aggregates as well as by the sufficiency of the cement content. The air-tightness of the concrete in the spiral casing and the roof over the turbine runner is obviously of great importance because of the evacuation of air from the syphon which we refer to hereafter.

In the construction of large masses of concrete, such as occur in the water passages and other parts of the turbine house, where some of the spans are as much as 20·5 m., it is preferable to avoid expansion and contraction joints. When this practice is followed it is of great importance that the heat rise of the concrete during the period of hardening should be kept as low as possible, and lower than that of concrete made with normal Portland cement, in order to minimise the risk of shrinkage cracks. The cement used in the Vargön works by the Royal Board of Waterfalls has been specially manufactured at the Limhamm Cement Works. It is a Portland cement, somewhat richer in silica than the normal cement, has a long setting and hardening time, and slow rise in strength but high final strength. It has a lower and less rapid temperature rise and less shrinkage than normal cement, and is more resistant to acid waters. The slow-hardening cement is otherwise equal to normal cement in physical characteristics and attains the same strength in about two months.

The total volume of concrete, nearly all reinforced, in the power station structure is about 12,500 cubic metres. The weight of the steel reinforcement is 2300 tons. The average weight of reinforcement is therefore about 184 kilos. per cubic metre of concrete, an exceptionally high value. The magnitude of the steel reinforcement built into the concrete of the turbine pit will be realised from the view—Fig. 21, page 494—of the lower guide wheel ring and the supporting columns for turbine No. 1. The position of the second turbine can be seen in the background. Fig. 20, page 494, shows the steel liner for the draught tube of No. 1 turbine in course of erection.

The waterways are made comparatively narrow, especially at the intake and at the spiral ; but, in order to facilitate the flow as much as possible, these waterways are constructed without any dividing walls. The intakes and diffusors (or draught tubes) therefore have unusually large spans—at some sections more than 20 m. This arrangement and the heavy loads which have to be carried by the roof of the turbine chambers have necessitated rather heavy reinforced concrete construction.

In the absence of ordinary sluice gates the intakes can be closed, when it is necessary for the purpose of examination or repairs, by means of vertical stop logs or needles. By means of built-up sections, consisting mainly of rolled steel joists, a structure can be put in position which has the same effect as steel sheet piling. Similar needles are provided for closing the draught tube outlets when required. When the needles are not in use they are stored on top of the intakes and draught tubes. The needles, which are placed in position by means of the derrick cranes on either side of the main travelling crane, and the sills against which they bear, are indicated in the cross section—Fig. 17. The intakes and the draught tubes, if repairs should be necessary, can be pumped out when the temporary needle dams are in position. For this purpose openings for the passage of submersible pumps are formed in the concrete roofs and drainage sumps have been cut in the rock floor. These openings can be plumbed by one or the other of the 6-ton derrick cranes.

The granite rock in which the lower parts of the intakes and draught tubes are excavated is very compact and free from important fissures. It was therefore decided to dispense with concrete linings and to dress the granite, wherever practicable, to form the walls and floors of the water passages—see Figs. 17 and 22. When excavating the rock, blasting was carried out with special care to avoid disturbance of rock which was to form a finished face. As the face was approached holes were drilled closer together and small charges were used for blasting. After the rock had been blasted away as close to the final face as was safe, further cuts were made by closely placed drill holes and chiselling out. The final dressing of rock surface is fine axed work. Fissures and holes in the granite, where they occurred, were filled with cement applied by a cement gun. A view of the rock excavation for the draught tube of unit No. 1 is reproduced in Fig. 22, page 494.

THE KAPLAN TURBINES.[*]

The general arrangement of the No. 1 unit, the first to be erected, is shown in the cross section and plan—Fig. 17. The two units are generally similar, the prin-

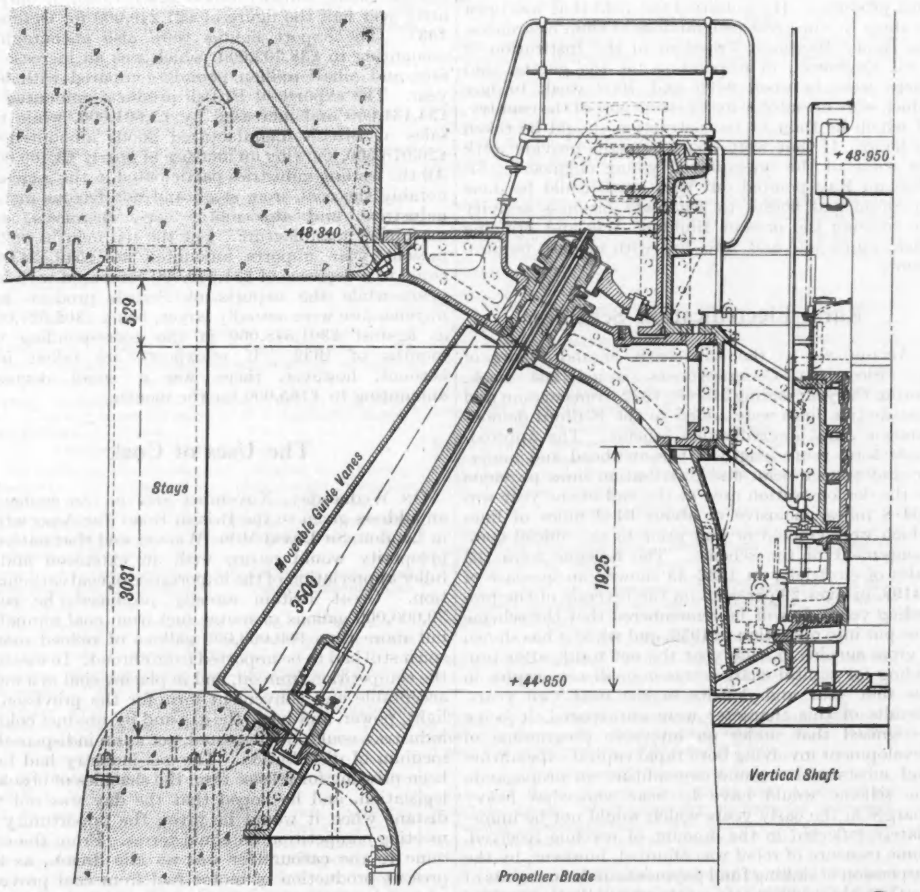

FIG. 16—PART OF CONICAL GUIDE APPARATUS OF KAPLAN TURBINE NO. 2—VERTICAL SECTION

cipal difference being that No. 2 has a conical guide apparatus, a detail of a part of which is reproduced in Fig. 16. It is intended that ultimately there will be three turbine units at the station. The following are the main particulars of the first and second units :—

---

[*] A good description of Kaplan turbines and recent Swedish practice will be found in "Report No. 86," by E. Engelsson, World Power Conference Papers, Scandinavian Meeting, 1933.

Manufacturers : No. 1, Verkstaden Kristinehamn (in co-operation with Boving and Co., London); No. 2, Verkstaden Kristinehamn and Nydquist and Holm (Nohab).

Effective head, 4·3 m.

Rating H.P.: No. 1, 15,200 ; No. 2, 14,800.

Discharge : No. 1, 330 cubic metres per second ; No. 2, 320 cubic metres per second.

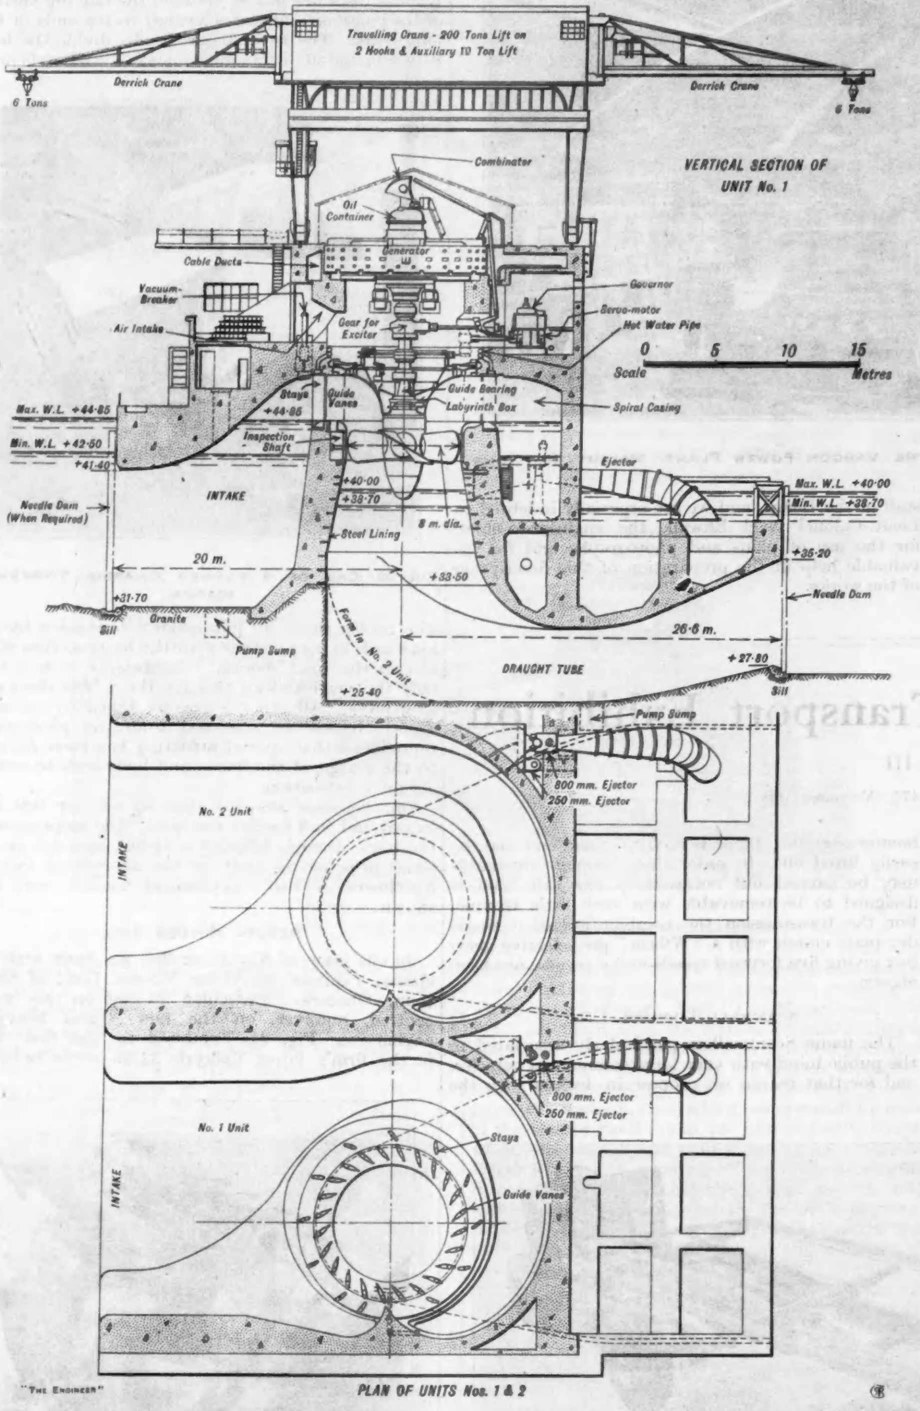
Diameter of runner, 8·0 m.

Diameter of hub, 2·94 m.

Weight of runner, 164 tons.

Speed, 46·9 r.p.m.

As already mentioned, the turbines are set above normal water level—that is, even at the maximum head water level the water does not rise above the guide-wheel foot. Before starting up the turbine water must be raised into the spiral casing by the ejectors. These have been arranged so that all four—see plan, Fig. 17—can serve one spiral casing. The small ejector in each turbine set is used to expel the air that gradually accumulates in the spiral casing during running. With this setting no intake sluices or gates are required. By admitting air into the spiral casing the water level in it can be lowered in a few seconds and the turbine ceases to get water. For this purpose there are two ports in the roof of the spiral çasing having together a sectional area of ½ square metre. Owing to the large dimensions of the turbines no trash racks have been provided at the intake ; consequently it is intended that all solids entering the intake shall pass through the turbines. The guide wheel cover is supported by twelve cast steel columns, which, as well as the guide vanes around the guide apparatus, are hollow. Provision is made to heat both the column and vanes, when necessary, by hot water to prevent the formation of ice. As the turbine will always work with a high vacuum, the labyrinth box has been submerged in a water container to prevent the admission of air.



IG. 17—VARGON HYDRO-ELECTRIC POWER STATION. KAPLAN TURBINE INSTALLATION—SECTION AND PLAN

Specific speed : No. 1, 934 ; No. 2, 922 ; (metric units).

Number and material of blades, four stainless steel, chipped and ground.

Draught tube type ; No. 1, Kaplan, square cornered elbow ; No. 2, Kaplan, curved elbow.

The gross head varies from 6·5 m. to 1·8 m. When the regulation has been completed the average head will be about 4·3 m. The maximum output of No. 1 turbine unit is 19,400 H.P. at 5·7 m. head. At 4·3 m. head the following efficiencies have been guaranteed :—

13,800	11,040	8280	5520	3460	H.P.
84·3 ..	88·5 ..	90·0 ..	88·2 ..	83·8%	efficiency

The lowest upper water level is at +42·50 m., and by means of the ejector it is raised to level +48·052.

The design of the turbine setting adopted for Vargön enables the machine to be closed down rapidly by admitting air into the spiral casing in the manner already mentioned. When the load is suddenly thrown off air is admitted into the draught tube in order to avoid water hammer. The air inlet ports are operated by an overspeed pendulum. On each turbine pit there are two hydraulically operated vacuum breakers affected by the overspeed pendulum. Thus, if the turbine should develop 50 per cent. overspeed, both vacuum breakers would open and in a few minutes they would admit enough air into the turbine pit to lower the water to the original level and the turbine would stop. The combinator with oil container is placed on top of the generator and is linked up with the governor by means of connecting-rods. Any guide wheel opening corresponds to a predetermined position of the runner blades and the different positions of the runner blades have been tested experimentally to give the best efficiency.

The regulating mechanism for the runner blades and the hub design are practically the same as have been used by Verkstaden Kristinehamn for all Kaplan turbines built in the past ten years. The design is characterised by the servo-motor being placed in the hub itself, the pressure oil being brought to the servo-motor by means of the hollow operating rod for the regulating valve in the motor. The runner blades are carried partly by a central trunnion to take the loads at right angles to the blades' turning axis, and partly by an outer bearing ring which takes care of the overhang. The hub is filled with oil under pressure, which is greater than that of the surrounding water, and so helps to prevent the ingress of water to the hub. A suitable double-acting tightening arrangement prevents oil from leaking out at the blade flanges and water or dirt from entering. The runner chamber is cylindrical. The second turbine has a conical guide apparatus and is built by Nydquist and Holm, but its runner has been made by Verkstaden Kristinehamn, who are responsible for the efficiency of both turbines.

The governor and its accessories are placed in spaces around the generator pit. The governor equipment consists in the main of the following parts : Air vessel ; oil reservoir ; pump ; regulating shaft and the servo-motor on which the pendulum and the regulating valve, as well as the other operating gears, are installed.

For the pressure oil supply there are two gear wheel pumps of different sizes. The large pump is connected direct to the exciter, which in turn is driven from the turbine shaft by means of bevel gears. This pump is normally running with no load. On the oil reservoir there is a small motor-driven pump, which is intended to supply the oil required under normal conditions when running and also when starting the turbine. The servo-motor is connected to the guide wheel regulating ring by means of connecting-rods and the regulating shaft, and is also operated by the system of connecting-rods and levers forming the combinator.

The pendulum is motor driven, current being supplied by a small generator on the shaft driving the exciter. If the pendulum motor circuit should fail, the guide wheel operation is locked. If the oil pressure in the air vessel should fall below a predetermined value, the turbine will be closed down. This, of course, also happens if the turbine attains a runaway speed. In the latter case also the vacuum breakers are opened. When any of the safety devices are in operation suitable signals are given and a signal is also made in the case of high temperature in the bearings.

Some idea of the huge dimensions of the turbines may be gained from the statement that each runner blade weighs 11 tons and the complete runner—Fig. 18—has a weight of 164 tons. The blades are of stainless steel and the runner chamber is made of welded steel plates. The use of stainless steel for the blades of Kaplan turbines has now become the normal practice in Sweden,* and both German and Swiss makers of Kaplan turbines are beginning to use this material for plants operating under relatively high heads. In the Vargön plant, not only are the runner blades of stainless steel, but also the upper part of the draught tube lining—that is, the section below the cylindrical runner chamber.

Generators.—Each turbine will be coupled to a three-phase generator rated at 12,000 kVA, 11 kV. One of the units is arranged for 25 c.p.s. and the other for 50 c.p.s. The 25-cycle unit will be connected with Trollhättan by means of an existing 11-kV line, while the 50-cycle unit will deliver energy to an outdoor 11/55-kV transformer for 12,000 kVA connected by a new line to the power station in Trollhättan. A motor generator and a storage battery for direct-current requirements will also be installed at the Vargön station.

The reason for the equipment of a new station with both 25 and 50 cycles machines is that the large industrial plants of the Vargön Aktiebolag nearby are equipped for 25 cycles and practically the whole output of one generator can be absorbed by them.

Distant Control.—The Vargön power plant will be controlled from the control room at the Trollhättan plant, 10 kiloms. lower down the river. From there the regulating gates in the barrage will be operated and the running of the turbines controlled.

The generators and other electrical equipment are being made by the Allmänna Svenska Elektriska Aktiebolaget, Västeras.

CONCLUSION.

The cost of the whole of the works at Vargön is expected to be about 14 million kronor (about

---

* See "Pitting in Water Turbines," Engelsson ; THE ENGINEER, October 17th, 1930.

£770,000 at par). Of this sum about 9 million kronor have been or will be spent on the power house and plant. The cost of the cofferdams for the power-house foundations was about 490,000 kronor, which appears to be a very moderate expenditure on such a difficult and complicated piece of work. Of this sum, 430,000 kronor is the expenditure on the upstream and downstream steel cofferdams, the balance being spent on a timber cofferdam on the east side of the power-house.

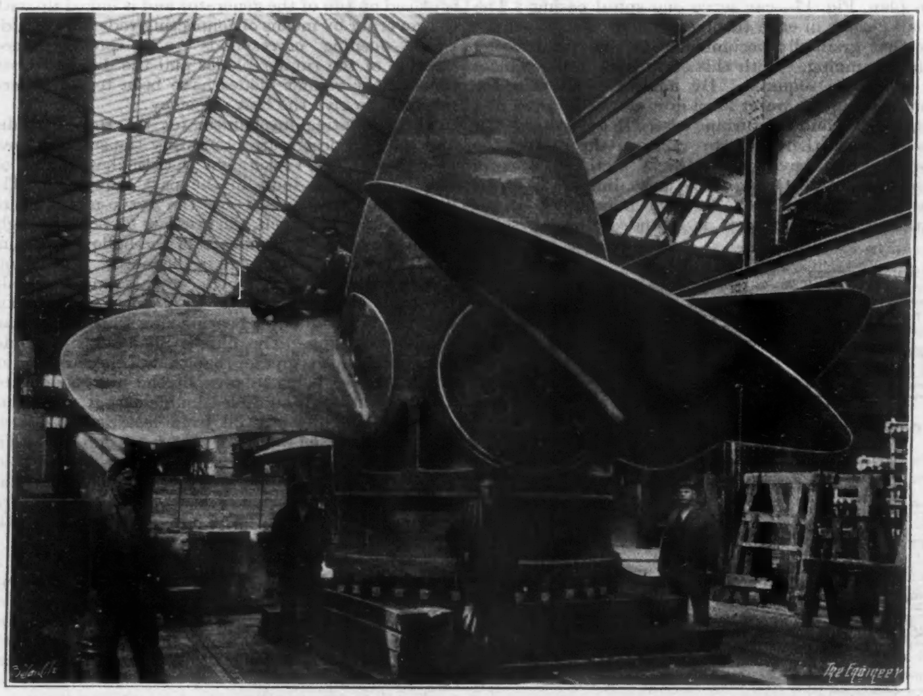


FIG. 18—KAPLAN RUNNER, 8 M. DIAMETER, FOR THE VARGON POWER PLANT. WEIGHT 164 TONS

The constructional works are being carried out by the Engineer's Department of the Royal Board of Waterfalls without the intervention of a contractor. All the works have been designed by the engineering staff of the Board, and we are especially indebted to Lieut.-Colonel Axel Ekwall, the engineer-in-chief, for the use of plans and photographs and for his valuable help in the preparation of this description of the works.

Commercial Motor Transport Exhibition.

No. III.

(Concluded from page 475, November 10th.)

THE YORKSHIRE PATENT STEAM WAGON COMPANY, LTD.

ON the stand of the Yorkshire Patent Steam Wagon Company, Ltd., of Hunslet, Leeds, there was shown an oil engine driven chassis having a load capacity of 6 tons. The makers state that for some time they have been observing the progress of the high-speed oil engine, and that they are now satisfied that this form of prime mover has reached a reasonable finality in design. It will be seen from the reproduced photograph, Fig. 29, that forward control has been adopted. The Dorman-Ricardo four-cylinder engine, developing 75 B.H.P. at 2200 r.p.m., is situated to one side of the cab. By raising the front cowling of the cab on the hinges by which it is supported at the top, access is gained to the electrical connections and the radiator elements, while within the cab the bonnet over the engine is in three parts and may be easily lifted off. In order that complete overhauls may be carried out occasionally the cab itself is designed to be removable with very little trouble. For the transmission the combination of a single dry-plate clutch with a "Wilson" pre-selective gear-box giving five forward speeds and a reverse has been chosen.

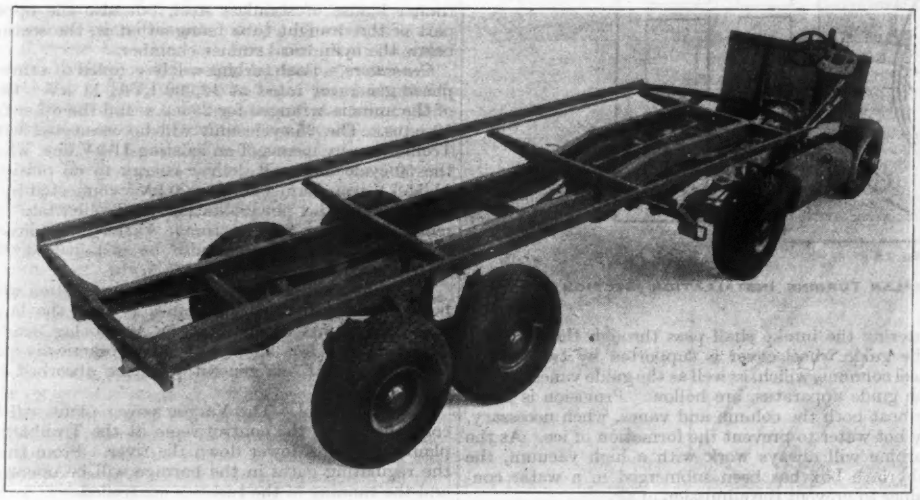

FIG. 28—ARTICULATED EIGHT-WHEEL CHASSIS—SCAMMELL

SCAMMELL LORRIES, LTD.

The name Scammell is particularly associated in the public mind with very large commercial vehicles, and for that reason we propose in dealing with the stand of Scammell Lorries, Ltd., of 52–54, High Holborn, London, to describe the articulated eight-wheeler with a maximum legal gross weight of 22 tons, shown at the Exhibition and illustrated by the engraving, Fig. 28. It is capable of carrying at least 15 tons useful load. This lorry is propelled by either a Scammell four-cylinder petrol engine, with an R.A.C. rating of 40 H.P. or a Gardner six-cylinder oil engine with an R.A.C. rating of 43 H.P. The engine is supported on a three-point rubber suspension.

The lorry has two particularly interesting features. First a six ratio gear-box is fitted, the highest ratio being an overspeed gear to give economical running on flat or down-sloping roads. The gears are of the constant mesh type, and are engaged by sliding dog clutches. Secondly, a novel means of suspension has been adopted for the rear bogie. Two parallel balance beams are pivoted at their centre to each end of a frame cross member, one at each side of the carrier frame. The ends of the balance beams have a pair of long bolts shackled to them. Each pair of bolts passes through and can slide in a trunnion mounted on each of the four axle arms. The trunnion axis coincides with the axis of its respective wheel. Rubber discs are placed between the flat top surface of the trunnion and plates secured to the ends of the long bolts. The two balance beams divide the load between, and allow free movement to, each axle arm.

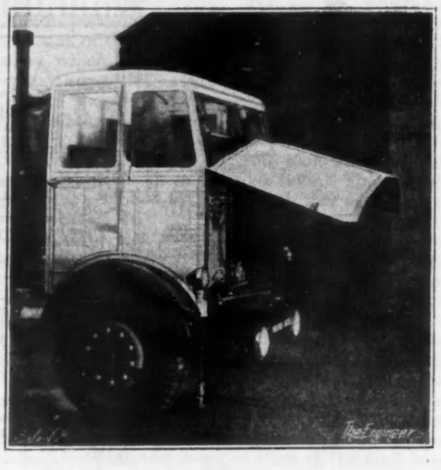

FIG. 29—CAB OF 6-TONNER CHASSIS—YORKSHIRE WAGON

The rubber discs are put under compression by the load and, in conjunction with the large section tires, absorb the road shocks. The balance beams take only the vertical load through the rubber discs and long bolts. All other forces are taken by the axle arms. It will be observed from the photograph reproduced that special attention has been devoted to the design of the frame and bodywork to obtain a light construction.

On the same stand a rigid six-wheeler was also shown and had similar features. The suspension of the bogie, though different in detail, operates on the same principle as that of the articulated vehicle. Specimens of the "mechanical horse" were also shown.

ALBION MOTORS, LTD.

In our issue of November 3rd we dealt with the chassis exhibits of Albion Motors, Ltd., of Scotstoun, Glasgow. Particular interest on this stand centred, however, on the new Albion heavy-oil engine—see Fig. 31—exhibited for the first time in the firm's latest Valkyrie 32/36-seater omnibus service chassis, which is normally fitted with the firm's 35/85 B.H.P. four-cylinder petrol engine. A wider range of operation is now given by the adoption of the heavy-oil engine, which has a bore and stroke of 4in. by 4¾in., and a rated output of from 35 to 70 B.H.P. at a maximum speed of 2200 r.p.m. The direct system of injection is used in conjunction with a C.A.V-Bosch fuel pump. The cylinder and crank case are formed as a single casting of strong proportions, and a feature of the design is the raised cam shaft, which is carried high up on the cylinder block, enabling a form of valve gear—see Fig. 30—very similar to that adopted on the petrol engine to be used. With the oil engine, however, the use of vertical valves has necessitated a slight alteration in the design. As the valves are directly

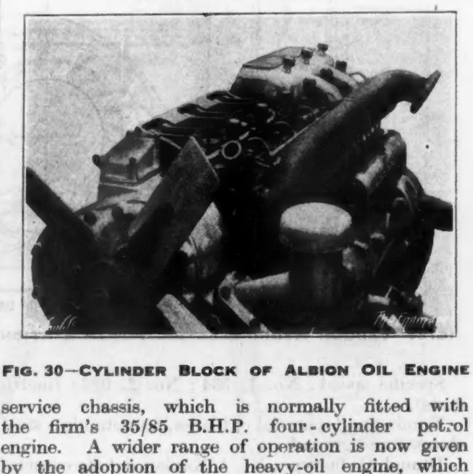

FIG. 30—CYLINDER BLOCK OF ALBION OIL ENGINE

operated from the cam shaft, the whole of the valve gear can be removed for adjustment or repair without altering the timing of the engine. The starting controls embody a neat form of decompression gear. Steel connecting-rods are employed, and special means have been adopted to ensure freedom from bearing trouble. When the new engine has undergone complete tests, it is hoped that further technical details and performance results will be available for publication.

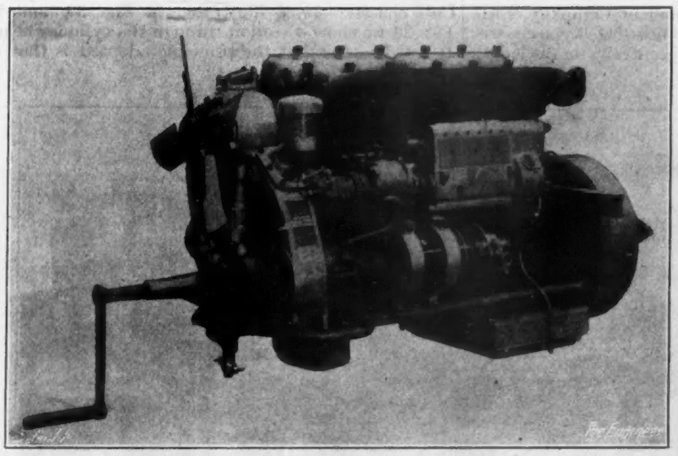

FIG. 31—70 B.H.P. SIX-CYLINDER OIL ENGINE—ALBION

KARRIER MOTORS, LTD.

Two new goods models to be known as the "Falcon" 3-tonner and the "Autocrat" 6-tonner are introduced by Karrier Motors, Ltd., of Huddersfield, for the 1934 programme, but only the first-named was exhibited at Olympia. Carrying a useful load of 3 tons, it has an unladen weight of 38 cwt. Being below the 50-cwt. tax limit, it is enabled legally to operate at 30 m.p.h. The chassis has a wheel base of 10ft. and is mounted on 32in. by 6in. tires. The power unit is a 24/49 H.P. four-cylinder overhead valve petrol engine in unit construction with the clutch and four-speed gear-box and it is mounted in rubber insulation in a frame of the cruciform braced type. Forward control has been adopted. Other models exhibited were the "Protector" 4-tonner, of which the front end has been re-designed and which has been fitted with hydraulic four-wheel brakes; and the "Bantam" 2-tonner, which has been improved in details, but shows little change otherwise except for the mounting of the engine in rubber insulation from the frame.

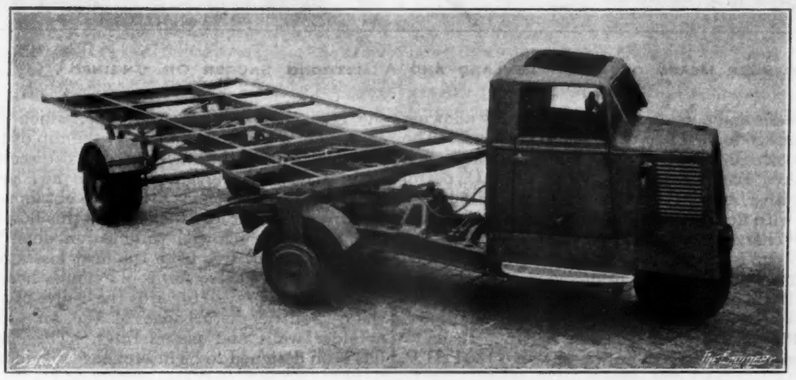

FIG. 32—"COB SIX" 14/52 H.P. THREE-WHEEL TRACTOR—KARRIER

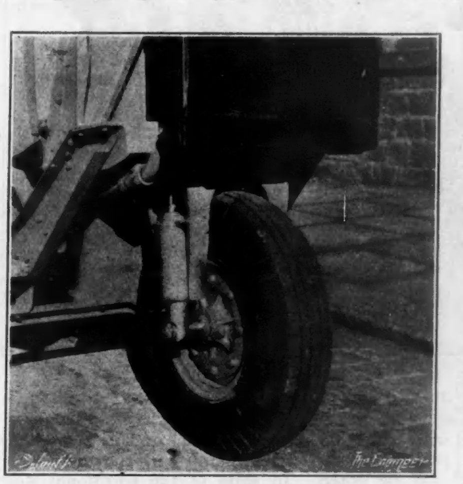

FIG. 33—FRONT SUSPENSION OF "COBS" AND "COLTS"—KARRIER

The effect of the new legislation, it is by no means impossible, will be to further increase the popularity of the three-wheel tractors made by the firm—the "Cobs" and "Colts." There is a newcomer in this range to be known as the "Cob-Six"—see Fig. 32. Whereas the "Cob Major," introduced in 1932, will deal with 4-ton loads on trailers of the quickly detachable type, the "Cob Six" will haul a 6-ton pay load. Its power unit is a six-cylinder 14/52 H.P. engine and it has servo-assisted brakes. In other features it is very similar to its forerunners, all of which have been improved as to the front wheel suspension. The new arrangement is illustrated in Fig. 33 and consists of dual helical springs and plungers instead of the semi-elliptics previously fitted. The steering also has been made lighter by the greater reduction given by the worm and wheel gear. Both "Cob Major" and "Cob-Six" are fitted with the Karrier automatic coupling and brake gear, by means of which trailers are rapidly attached and detached from the tractor without the need for the driver-operator to leave his seat. Furthermore, the trailer brakes, which are operated by means of the tractor hand brake, are automatically coupled when the tractor and trailer are brought together. When a tractor is operating with two or more trailers it is highly probable that the brakes on each trailer will not be adjusted to exactly the same degree, or possibly the brakes of one trailer may be rather more worn than those of the tractor, in which case it will be obvious that a fixed braking system through the tractor would not be efficient. This difficulty has been overcome by the incorporation of a dual braking lay-out, by means of which the direct system employed when the tractor is running solo is quite simply changed over to a compensated one, which is used when the tractor is coupled to a trailer.

In connection with bodywork the firm announces that arrangements are well in hand for the production of bodies built upon light steel underframing, by which means considerable savings in weight are to be effected.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY, LTD.

The exhibits on the stand of the Bristol Tramways and Carriage Company, Ltd., were principally confined to single and double-deck omnibus chassis of the company's own design and manufacture, which are available either with the firm's own petrol motor or the Gardner heavy oil engine. One of the main exhibits was the "G" type Bristol chassis for a 52-seater, double-deck omnibus which is equipped with the six-cylinder Bristol petrol engine illustrated in Fig. 34. This is a 2000 r.p.m., 103 B.H.P. engine, with an R.A.C. rating of 41 H.P., having a bore of 105 mm. and a stroke of 140 mm. It is complete with C.A.V.-Bosch magneto, starter, and lighting dynamo, and is fitted with syphonic cooling. The engine works in conjunction with a four-speed gear-box with the firm's patented selector gear, and the transmission includes a full floating worm-driven rear axle. The company's cam type spring fittings are used, and there are servo-assisted brakes of the Dewandre type. The tires are high-pressure, 36in. by 8in., and the wheel base is 16ft., the complete weight of the chassis being 4 tons 5 cwt.

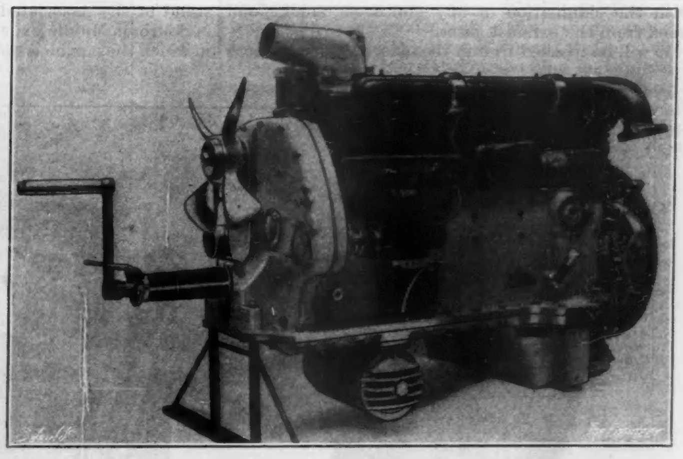

FIG. 34—103 B.H.P. SIX-CYLINDER OIL ENGINE—BRISTOL

Another model is the "J" type Bristol chassis, which was shown equipped with a four-cylinder, 103 B.H.P., Bristol petrol engine and an overspeed gear-box. This model is, however, available with three different petrol engines and an 85 B.H.P. five-cylinder Gardner heavy oil engine. Some fine examples of all-metal omnibus construction were also shown on the stand.

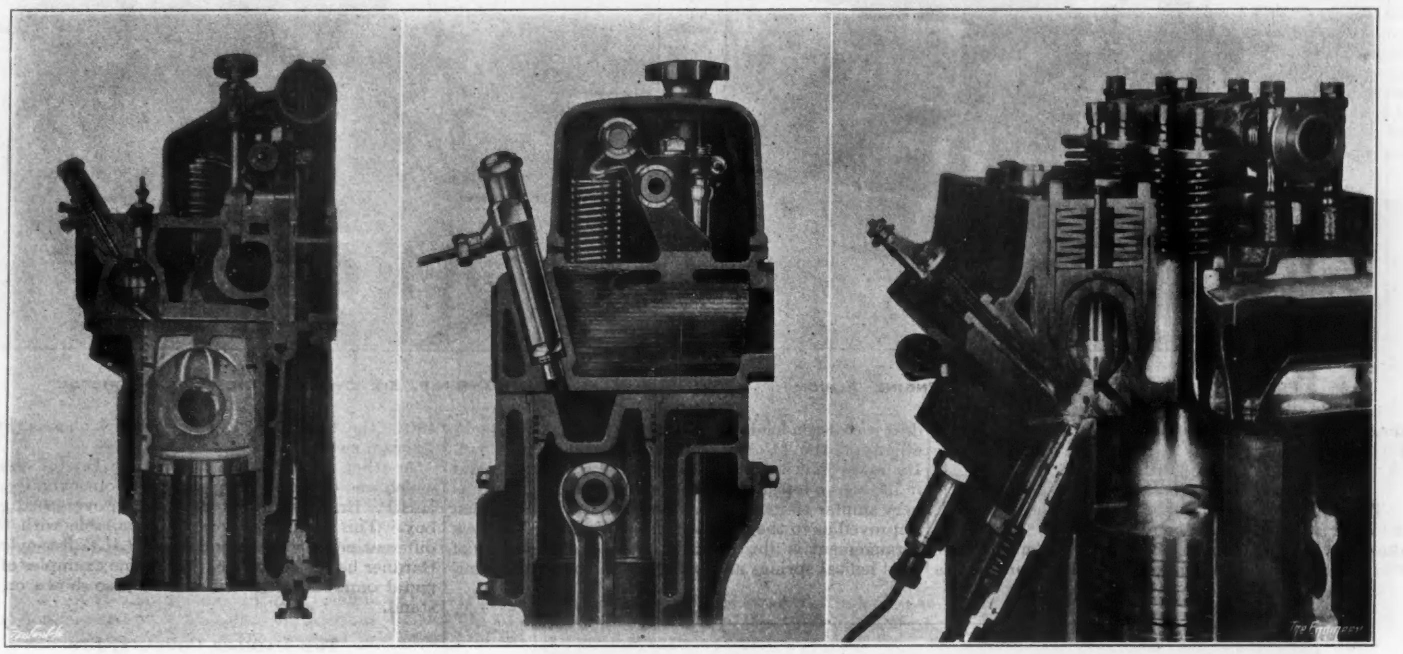
THE DAIMLER COMPANY, LTD.

Prominent on the stand of the Daimler Company, Ltd., of Daimler Works, Coventry, was a large working model of the fluid fly-wheel transmission gear, in which the moving fluid was ingeniously represented by coloured rubber balls circulating within half-couplings of wire mesh. The firm's exhibits were mainly designed to show the advantages gained by the adoption of the fluid fly-wheel transmission in combination with a pre-selective self-changing gear-box. Several double and single-deck omnibus chassis were on view, for which either six-cylinder Daimler poppet valve or sleeve valve engines are available or the Gardner five-cylinder oil engine with a bore of 108 mm. and a stroke of 152·4 mm. and a capacity of 7046 cubic centimetres. This engine, combined with the fluid fly-wheel and a five-speed self-changing gear-box, is claimed to give an absence of difficult gear changing, more economical running, and a higher degree of road safety. The engine can, with this arrangement, be stopped and started at will with the drive engaged and the engine running. Features of the Daimler chassis include a very low frame level with a sturdy and simple construction. The weight of the chassis has also been considerably reduced by the extensive use of high-tensile aluminium alloys, such as are commonly employed in aircraft construction.

ARMSTRONG-SAURER.

On the large stand of Armstrong-Saurer Commercial Vehicles, Ltd., there were exhibited three new oil-engined lorries, which have been specially designed to meet the new system of taxation. They comprise the "Active" and "Effective" four-wheeled models and the "Dynamic" a new six-wheeled vehicle. The principal features of the chassis structure include the use of light steel members and light alloys, which, while maintaining undiminished strength and a high safety margin, have resulted in a very advantageous ratio between the unladen weight and the pay load capacity. Thus in the case of the four-wheeled models the taxation class is 4 to 5 tons and the legal pay load capacity 7 to 8 tons. For the six-wheeled model the taxation class is 7 to 8 tons and the legal pay load capacity 12 tons. All the vehicles can now be arranged for either forward or normal control. In the case of the forward control the engine is placed in the centre of the cab with seats for the driver and his mate, one on either side. Particular attention, we noted, has been paid to the lay-out of the controls, which give a roomy cab, combined with a convenient driving position. A new feature is a sliding roof for the cab, which enables the ventilation to be controlled as may be desired. In fixing the position of the engine the greatest accessibility has been allowed for. Other features of the new chassis are an improved easy steering mechanism, air pressure brakes, and a gearbox giving eight forward speeds. Body lengths up to the legal 24ft. 6in. with forward control are now available. Either the four-cylinder 70 B.H.P. engine or the six-cylinder 110 B.H.P engine can be fitted. Particular interest attaches to the new compensating mechanism in connection with the braking of six-wheeler chassis, which was exhibited on the stand.

A sectioned 110 B.H.P. engine—see Fig. 37—having a bore of 110 mm. and a stroke of 150 mm., shows clearly the cross flow system of fuel injection, which has now been adopted by the company in all its new models, and which, it is stated, has resulted in an increased horse-power of from 10 to 15 per cent. with the elimination of any obnoxious smoke and smell from the exhaust gases.



FIGS. 35, 36 AND 37—SECTIONS THROUGH CYLINDER HEADS OF A.E.C., LEYLAND AND ARMSTRONG SAURER OIL ENGINES

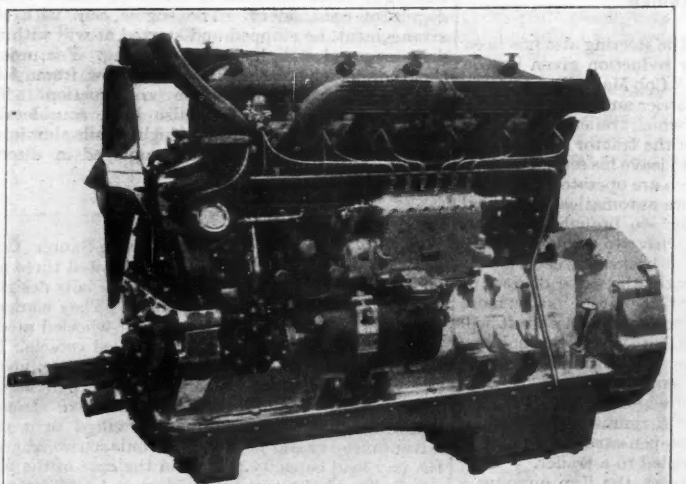


FIG. 38—130 H.P. SIX-CYLINDER OIL ENGINE—A.E.C.

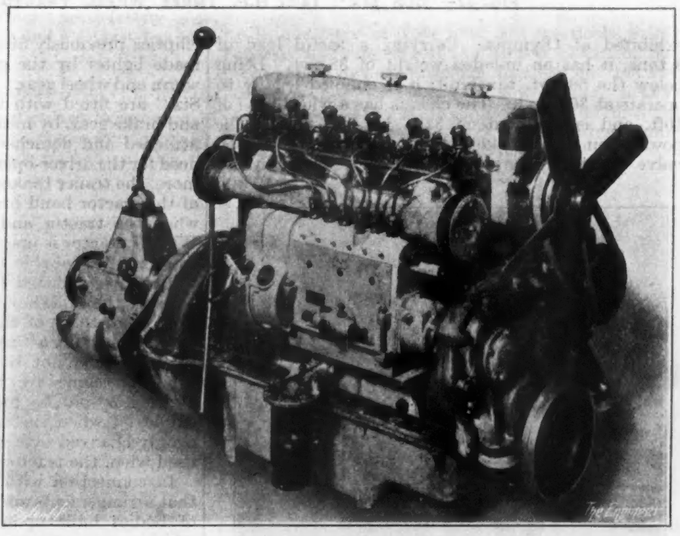

FIG. 39—60 B.H.P. "LIGHT SIX" OIL ENGINE—LEYLAND

It will be recalled that in the older models the Acro system of air cell construction was employed, in which the air during compression was forced through a funnel-shaped opening terminating in a narrow neck connecting with a dome-shaped air cell in the cylinder head. The fuel spray was so directed that it met the turbulent stream of air issuing from the air cell orifice into the combustion chamber, but the relative angle between the injected fuel and the air stream did not permit the fuel to penetrate freely the extreme air particles which had an effect on the available output. In the new Armstrong-Saurer cross flow system, illustrated in Fig. 37, the conditions governing the combustion process are entirely different. The air is now compressed into the air chamber or cell through a long passage which lies at a tangent to the circular lower portion of the domed cell, thereby compelling the air stream to rotate in a predetermined manner, giving an ordered turbulence. The fuel spray is now designed to meet the air current almost at right angles and so to produce a homogeneous mixture of air and fuel particles. By means of the correlation between the timing and duration of the injection period with the swirling air current a thorough saturation of the air with fuel is effected, which, it is claimed, remains constant with varying engine revolutions. It thus becomes quite unnecessary to vary the point of injection with engine speed and the vehicle can be driven with fixed injection timing. The standard Bosch pump and injectors are employed, and our illustration clearly indicates the relative positions of the swirl chamber, the fuel injector and the heating element. The series of corrugated steel washers giving flexible pressure to the top of the domed air chamber may be noted.

THE ASSOCIATED EQUIPMENT COMPANY, LTD.

One of the most interesting of the exhibits on the stand of the Associated Equipment Company, Ltd., of Southall, Middlesex, was the new "Q" type chassis, in which the engine is mounted centrally on the length of the chassis and outside the frame, thereby allowing full advantage to be taken of all the body space. The double-deck omnibus chassis and a long-distance coach shown have 120 B.H.P., 2000 r.p.m., A.E.C. petrol engines with a bore of 110 mm. and a stroke of 130 mm., working with fluid fly-wheel transmission and a four-speed self-changing epicyclic gear-box. A feature of the chassis design is the 11in. by 3in. pressed frame, which sweeps down at the nearside front end in order to facilitate low loading. The goods carrying models included the "Matador" 7½-ton lorry and the "Mammoth Major" 12½-ton light-weight chassis. On the "Regent" type of omnibus chassis there was shown a 130 B.H.P. A.E.C. standard oil engine, Fig. 38. This unit was also to be seen on the Hardy rail car, which was fully described and illustrated in our recent issue of October 27th; while on the A.E.C. stand a sectioned model of the four-cylinder engine attracted much attention—see Fig. 35. Since we described the A.E.C. oil engine at the last Commercial Motor Exhibition progress has been made in its design. The use of special alloys has given lightness of construction combined with maximum strength. We may briefly refer to the Elektron metal crank casing, the special hardened liners and hardened piston rings, and the alloy steels used in the manufacture of many of the important parts of the engine. Special spun copper-lead-bronze is used for the wearing parts of the bearings and has been attended with excellent results.

LEYLAND MOTORS, LTD.

The extension of the heavy-oil engine to the smaller range of commercial vehicles, is well illustrated by the new light-six oil engine designed by Leyland Motors, Ltd., of Leyland, Lancashire, and Kingston-on-Thames, for the well-known Leyland Cub chassis. It is illustrated in Fig. 39, and in Fig. 36 we show a section through the cylinder head. It will be seen that the principle adopted is that of the Leyland direct-injection type, which essentially consists of a simple open cup in the top of the piston towards which the fuel spray is directed. The natural upward movement of the air, as it enters the combustion space, is utilised to obtain a thorough mixture of the air and fuel, and as this flow is orderly and non-reversing, the combustion chamber shape is claimed to be free from the heat losses of some of the more complicated forms of cylinder head. Again, as the fuel is sprayed towards the centre of the piston, there is little disturbance of the oil film on the cylinder walls and piston rings. The engine itself has been designed to be interchangeable in the chassis with the Cub petrol engine, and the very neat positioning of the fuel pump unit shown in Fig. 39 may be noted. In spite of the additional weight of the fuel pump and the more robust electrical equipment, the complete engine only weighs 850 lb., and it occupies no more space in the chassis than does the six-cylinder petrol engine.

It has six cylinders, each with a bore of 3⅜in. by 5in., the displacement being 268·4 cubic feet, or about 4·4 litres. It is designed to develop 28 B.H.P. at 1000 r.p.m., and 60 B.H.P. at its governed speed of 2400 r.p.m. We were permitted to make an extended trial run in Surrey on one of the "Cub" goods vehicles fitted with the new engine, and found it to be exceptionally smooth and quiet in its running throughout its speed range. It started up easily, without the use of electrically heated glow plugs or other auxiliary apparatus, and on hills it exhibited that reserve of power which is peculiar to the oil engine as compared with the petrol motor. Some constructional features of the new engine include a monoblock cylinder casing and crank case, which is fitted with centrifugally cast cylinder liners of special quality metal. The pistons are made of heat-treated aluminium alloy, and each carries three compression rings and an oil scraper ring. The connecting-rods are also made in aluminium alloy, which is heat treated, and a further interesting feature of the design is the fact that bottom end bearing shells are done away with and the aluminium alloy is run in direct contact with the hardened surface of the crank pin. The fuel injection gear is of the C.A.V.-Bosch pattern with single-hole sprayers. The lubricating oil system is generally similar to that employed on petrol engines, and it includes a fabric type oil filter. Air filters are fitted to each end of the intake manifold, and the starting equipment consists of a 24-volt C.A.V.-Bosch starting motor with a dynamo for lighting. The engine we have described is a notable addition to recent heavy-oil engines.

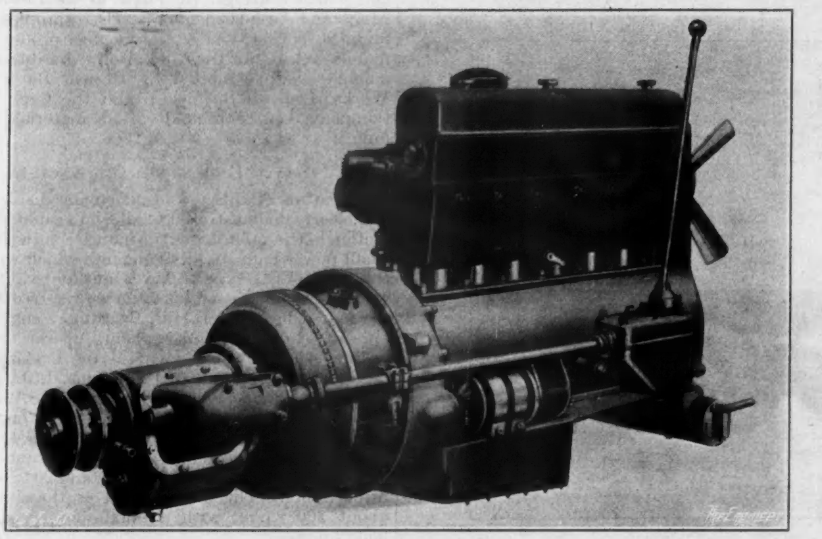

FIG. 40—110 B.H.P. PETROL ENGINE AND TORQUE CONVERTER—LEYLAND

Any description of the Leyland stand would not be complete without a reference to the Leyland hydraulic torque converter, working on the Lysholm-Smith principle, which was shown as a unit construction in combination with a six-cylinder 110 B.H.P., 2200 r.p.m. petrol engine, installed in a 26-seater "Tiger" luxury coach. The complete unit is shown in Fig. 40. For a full description our readers may be referred to our issue of October 13th, 1933.

THE SENTINEL WAGGON WORKS, LTD.

Much interest centred around the vehicles shown on the stand of the Sentinel Waggon Works, Ltd., of Shrewsbury, and London, these being, to the best of our knowledge, the only steam-operated vehicles shown at Olympia. They included the smaller 6 to 7-ton four-wheeled models shown with plain and hydraulically operated tipping bodies, one of these models being fitted with the firm's latest automatic stoker and feed water regulating apparatus. The 10 to 12-ton models were also on view, but we have chosen for illustration the new eight-wheeled vehicle for 13-ton legal loads shown in Fig. 41. This is interesting, not only on account of the very neat engine, boiler, and cabin lay-out which has been provided, but also because of the novel four-wheel steering device, illustrated in Fig. 42. As the engraving shows, there are two drop forged steel axles carrying wheels at either end. These are connected to the ends of strong flexible springs, the central bearings of which pivot on the cross members of the brackets, which in turn are attached to the frame of the chassis. The main axle wheel base is 14ft. 4¾in. and the front bogie centres 3ft. 5½in., those of the rear bogie being 4ft. with a 6ft. 4¾in. track. The front wheels carry single 36in. by 7in. tires and the rear wheels 38in. by 8in. twin tires, all of which are of the detachable disc pattern. With a 20ft. long flat platform type body and cab the chassis weight is 7 tons. The power unit is the new glandless four-cylinder single-acting non-compound steam engine, which has a bore of 5½in., a stroke of 6in., and is designed to develop 120 B.H.P. when supplied with steam at 225 lb. pressure. The boiler is of the firm's latest large-tube type and is arranged for hand firing, the fuel compartments being so contrived as to give a gravity feed. The engine cam shaft is designed for three forward and one reverse cut-off positions. There is a unit construction type of two-speed gear-box and the transmission is by a Hardy-Spicer cardan shaft drive to the four-wheel rear bogie through double reduction gears, the drive being from spiral bevel gear to double helical gear. Both the front and the rear bogies are fully compensated, there being front all-wheel steering, as already mentioned, with rear braking and torque reaction on the Hotchkiss system. On the stand there were shown the principal constructional parts of the engine and the transmission drive, and we were impressed by the evident care which has been taken in simplifying the design of the steam engine and boiler, the engine construction having been carried through on lines not far removed from those of standard oil engine practice. It is of interest to record that the 120 B.H.P. engine weighs barely 9 cwt.

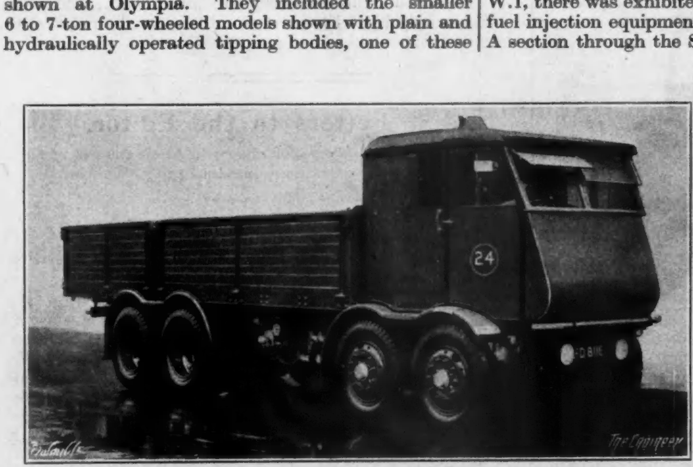

FIG. 41—RIGID EIGHT-WHEELER STEAM WAGON—SENTINEL

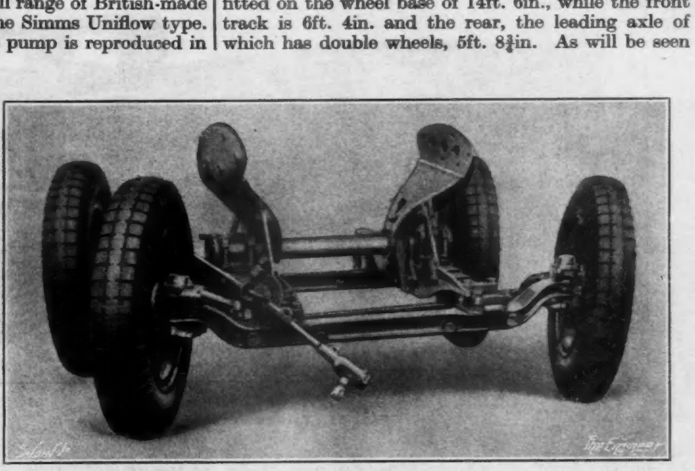

FIG. 42—FRONT STEERING BOGIE OF STEAM WAGON—SENTINEL

SIMMS MOTOR UNITS, LTD.

On the stand of Simms Motor Units, Ltd., of Percy Buildings, Gresse-street, Rathbone-place, London, W.1, there was exhibited a full range of British-made fuel injection equipment of the Simms Uniflow type. A section through the Simms pump is reproduced in Fig. 43. Assuming the pump to be filled with oil and the plunger near to the end of its stroke, as shown in the drawing, the upward movement of the plunger compresses the oil and delivers it through the spring-loaded valve into the pipe leading to the injection nozzle. If in response to governor or hand control an earlier cut-off is required, the plunger is slightly rotated by a rack motion, which at a pre-determined point in the plunger stroke brings the helix cut in the plunger into coincidence with the helical edge of the port cut in the upper end of the barrel. When this takes place the oil under pressure spills into the helical channel of the plunger and is ejected tangentially at high velocity into the spill annulus, rejoining the entry stream in the suction inlet pipe and part of it passing with this downward suction stroke through the suction ports and the suction annuli into the working chamber. The direction of flow of the oil through the suction ports is always the same, namely, in an upward direction, giving a uniflow system of operation. On the stand an electrically operated model with a stroboscopic arrangement of lighting clearly demonstrated the form of oil spray obtained with the Simms pump and injection nozzle. The pumps are available as single-flanged units without cams or complete self-contained single or multi-cylinder units with or without injection timing controls or governors. The sizes available are 6 mm. and 7 mm. bore with strokes of 7·5 mm. and 8 mm. and 10 mm. and 11 mm. bore with a stroke of 10 mm. For use in connection with the Simms fuel injection equipment the firm has recently introduced a new simple form of self-cleaning filter for fuel oil and other industrial uses, which was also exhibited on the stand.

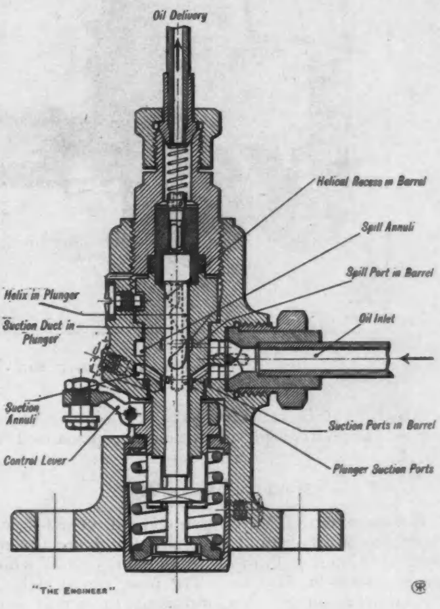

FIG. 43—FUEL PUMP—SIMMS

PAGEFIELD COMMERCIAL VEHICLES, LTD.

On the stand taken by Walker Brothers (Wigan), Ltd., of 40/42, Quadrant House, Pall Mall, London, there was to be seen a new 7-ton light rigid six-wheeled lorry known as the "Pegasix," designed by Pagefield Commercial Vehicles, Ltd., of Pall Mall, London. This lorry is propelled by a Gardner 5 L W oil engine, developing 85 B.H.P. at 1550 r.p.m., which is suspended in the frame by silentbloc bushes. The main frame of the vehicle is of 10in. channel section pressed steel, and the whole design is light and flexible, while, at the same time, amply strong. A platform, 16ft. 6in. or 19ft. 2in. in length, may be fitted on the wheel base of 14ft. 6in., while the front track is 6ft. 4in. and the rear, the leading axle of which has double wheels, 5ft. 8¾in. As will be seen from the engraving, Fig. 44, forward control has been adopted, and the front axle is set back. The turning circle is between 54ft. and 58ft. Four forward speeds and reverse are provided by the gear-box, which is in unit construction with the engine. All the gears are ground, on their splines, to accurate tooth profile after hardening. Self-energising brakes of the Bendix-Perrot duo-servo type, acting on all the wheels and operated either by foot or by hand, provide for the safety of the vehicle on the road. The whole lorry has been designed to permit of easy maintenance, and with this point in view accessibility has been carefully studied. At the same time, the unladen weight has been kept as low as possible consistent with safety. Complete with its cab, platform, and engine, it weighs 4 tons 17 cwt., and the fuel consumption, according to the makers, works out at 130 ton-miles per gallon. The actual lorry exhibited at Olympia had a large van body, but in other respects was similar to the vehicle, a photograph of which is reproduced in Fig. 44.

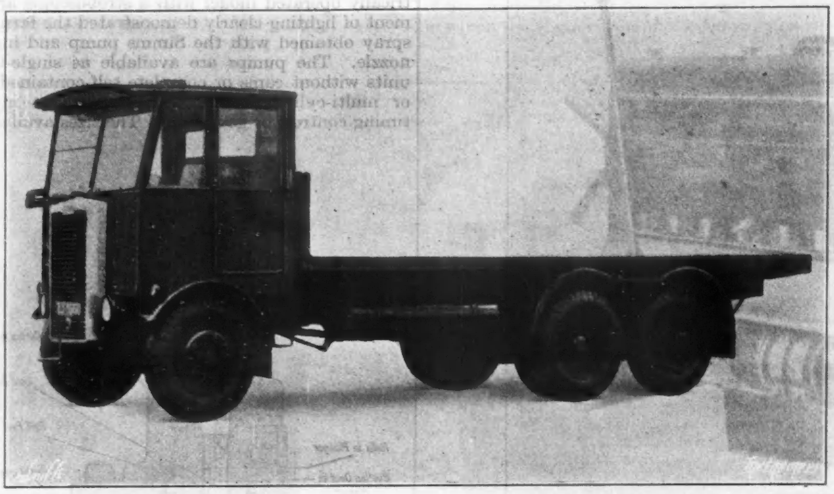

FIG. 44—LIGHT SIX-WHEEL LORRY—PAGEFIELD

MORRIS-COMMERCIAL.

A wide range of Morris-Commercial vehicles was displayed on the stand of Morris Commercial Cars, Ltd., of Adderley Park, Birmingham, one of which we illustrate in Fig. 45. The new range includes 30-cwt. to 3-ton vehicles, and also 3½-ton and 5-ton models, all of which embody special new features derived from the firm's extensive road experience. Four and six-cylinder engines are available with either normal or forward controls. The new design of chassis is specially strengthened with triangulated frame bracing, which, it is claimed, doubles the strength at the most important sections. The springing is special in that the springs are progressive and automatically vary the suspension according to the load which they are called upon to deal with. Lockheed hydraulic brakes are fitted to each of the four wheels and the gear-box is of the four-speed, silent, twin-top pattern. One of the largest vehicles was a double-deck omnibus chassis known as the "Imperial," which is equipped with a six-cylinder, 110 B.H.P. engine, a feature of which is the high arrangement of the cam shaft and the particular design which enables the power unit to be wheeled out on the front axles when repairs or adjustment are required.

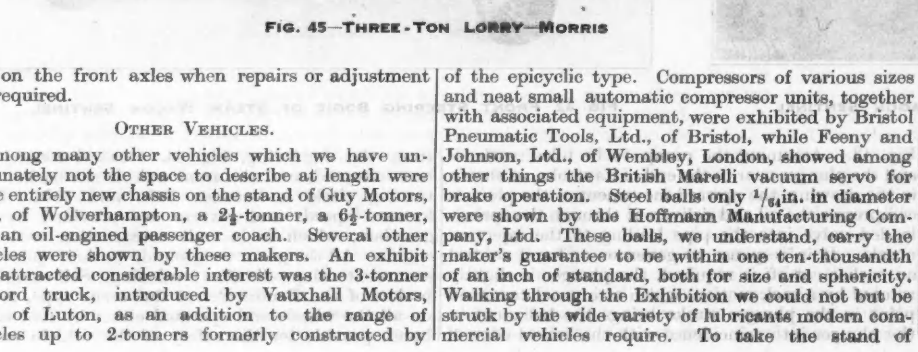

FIG. 45—THREE-TON LORRY—MORRIS

OTHER VEHICLES.

Among many other vehicles which we have unfortunately not the space to describe at length were three entirely new chassis on the stand of Guy Motors, Ltd., of Wolverhampton, a 2½-tonner, a 6½-tonner, and an oil-engined passenger coach. Several other vehicles were shown by these makers. An exhibit that attracted considerable interest was the 3-tonner Bedford truck, introduced by Vauxhall Motors, Ltd., of Luton, as an addition to the range of vehicles up to 2-tonners formerly constructed by the firm. Tankers of various types were shown by the Steel Barrel Company, Ltd., of Uxbridge, and Carrimore, Ltd., of North Finchley, London, showed two trailers, one a 5/6-ton and the other an 8-ton, besides six-wheeler attachments. An attractive vehicle was the 350/450-gallons per minute motor fire engine, exhibited by Halley Motors, Ltd., of Yoker, Glasgow. The fire pump is mounted at the rear of this machine, and is fitted with two delivery valves and a 4in. suction inlet. It is driven through a chain from an auxiliary gear-box in the chassis transmission line. Several other vehicles were exhibited by this firm. Fodens, Ltd., of Sandbach, Cheshire, exhibited a number of oil engine driven vehicles, and the novel bogie suspension system on the stand of Longframe Six-wheeler Construction Company, of Copenhagen, attracted considerable attention. There were a number of interesting exhibits on the stand of the Truck and Tractor Appliance Company (Manchester), Ltd., of which we may mention the twin-spring suspension arrangement, one spring above and the other below the axle, and the neat "pick-up" gear for the attachment of a semi-trailer.

ACCESSORY AND DETAILS.

A large amount of space in the Exhibition was taken by the makers of accessories and of garage equipment, &c. Among the firms showing such productions, David Brown and Sons (Huddersfield), Ltd., exhibited gears of all types and hobs and cutters for their manufacture; in addition, there was to be seen on the stand a new type of "Roots" supercharger. The grinding of gears was represented by the Gear Grinding Company, Ltd., of Handsworth, Birmingham, which exhibited specimens of ground gears, the involute gear-testing machine we described some months ago, and the parts of pre-selective gear-boxes of the epicyclic type. Compressors of various sizes and neat small automatic compressor units, together with associated equipment, were exhibited by Bristol Pneumatic Tools, Ltd., of Bristol, while Feeny and Johnson, Ltd., of Wembley, London, showed among other things the British Marelli vacuum servo for brake operation. Steel balls only $^1/_{64}$in. in diameter were shown by the Hoffmann Manufacturing Company, Ltd. These balls, we understand, carry the maker's guarantee to be within one ten-thousandth of an inch of standard, both for size and sphericity. Walking through the Exhibition we could not but be struck by the wide variety of lubricants modern commercial vehicles require. To take the stand of Sternol, Ltd., as an example, there were shown eight different types of oil, not to mention the various grades in each type and the range of greases. All kinds of fittings for commercial vehicles were shown by the A.C.-Sphinx Sparking Plug Company, Ltd., of Birmingham, including, of course, sparking plugs, oil gauges, petrol gauges, speedometers, whilst clocks, &c., were also to be seen. The Skefko Ball Bearing Company, Ltd., showed the range of products, ball and roller bearings, produced in its Luton works. Alloy and case-hardening steels, examples of drop forgings, spring steel, stainless steel products, automobile axles and the "Johnson" hardness testing machine were exhibited by Brown, Bayley's Steel Works, Ltd., of Sheffield; and the Cape Asbestos Company, Ltd., exhibited various materials for brake linings.

SMALL HIGH-SPEED OIL ENGINES.

A feature of this year's oil engine display, which was clearly demonstrated to all who visited the engine section in the gallery, was the increase in the number of small power high-speed oil engines, which will extend the range of this type of power unit for road transport work. In our last week's issue we referred briefly to the four-cylinder 45 B.H.P. Beardmore engine with a bore of 3½in. and stroke of 5in., operating at 2400 r.p.m. Another small engine is the Perkins car size motor, manufactured by F. Perkins, Ltd., of Peterborough and 55, Pall Mall, London, S.W.1. This firm supplies three models with bores of 3in., 3·15in., and 3·35in. with a common stroke of 4¾in., with designed power outputs over a speed range of 1000 to 3000 r.p.m. of 16 to 40, 18 to 45, and 20 to 48 B.H.P. respectively. The idling speed of these engines is about 300 r.p.m. with a maximum speed of over 3500 r.p.m.

Another small engine, Fig. 46, was shown on the stand of J. and H. McLaren, Ltd., of Midland Engine Works, Leeds, which firm exhibited a four-cylinder unit having an output of 36 to 50 B.H.P. over a speed range of 2000 to 3000 r.p.m. The model referred to is a short-stroke engine, which has the advantage of a low piston speed at high revolutions, a piston speed of 1650ft. per minute being attained at 2500 r.p.m. The complete engine with its fly-wheel, exhaust manifold and electrical equipment only weighs 700 lb., and with specially light Electron metal this can be reduced to 600 lb.

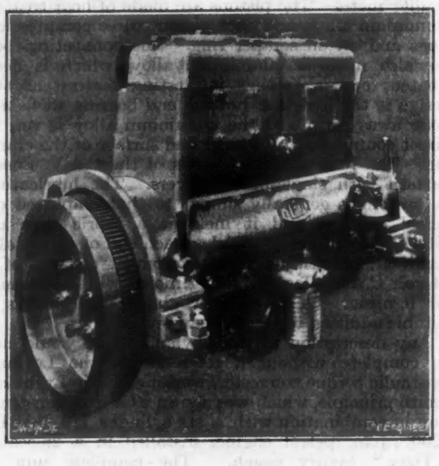

FIG. 46—50 H.P. OIL ENGINE—MCLAREN

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

WATER LOWERING IN QUICKSANDS.

SIR,—Mr. T. L. Reed Cooper's letter in your issue of November 3rd and that of "Waterworks Engineer" are not without interest.

Those who attended Sir Henry Japp's paper, or who read it carefully in your columns, will recognise that Mr. Reed Cooper's generalities give an erroneous presentation of the case, and it is to be regretted that he did not participate in the discussion, which was promoted for the very purpose of enabling persons interested to express their views and to give the reader of the paper opportunity to answer any detailed criticism.

It is not fear, but partly financial considerations, which prevent such systems as ground water lowering developing first in this country. New systems naturally develop where existing conditions create the urge or give the greatest opportunity. This was the case in the development of shield-driven tunnels in this country and of heavy excavating machinery in the U.S.A.

The geological conditions in North Germany and the Low Countries are such that a great and continual need exists for the evolution of means to deal with water-bearing grounds. In the case of the process of ground water lowering by deep-well pumps in filter wells, engineers, contractors, and pump manufacturers were all embodied in one very efficient organisation, which could handle the long and costly evolution of the system which has given such satisfactory results.

British conditions in carrying out large contracts do not lend themselves readily to organised gradual development of new methods.

That we should benefit by German experience is no more lamentable than the fact that a British firm built shield-driven tunnels under the rivers of New York.

Mr. Reed Cooper's submersible pumps are well known, and his patents for bore-hole pumps can be studied in the Patent Office Library, but it would be interesting to know whether really suitable pumps of tried reliability and in sufficiently large numbers were available for immediate use at the time the works described in the paper had to be put in hand.

If "Waterworks Engineer" were to read the paper more closely he would see that "unwarranted claims of novelty" were not made and his whole letter seems based on misconceptions.

It is to be hoped that, on mature considerations, he regrets having made an uncalled-for attack under a pen-name upon the Southern Railway and their engineers. This company by its bold undertakings at Southampton, has done so much to create employment and ensured a wide scope for British plant. Their engineers have been engaged upon works of great importance and serious responsibility, and they expressed their appreciation of having been able to avail themselves, in time of urgent need, of the experience of those who were in a position to offer, not advice, but immediate skilled assistance and equipment of proved dependability.

H. J. B. HARDING.

London, S.W.15, November 13th.

SIR,—In 1838 Robert Stephenson by forming a cone of depletion through water-logged sand was able to construct the Kilsby Tunnel ("Proc.," Inst. C.E., Vol. CXXXIV., pages 255, 256, Dawkins on "The Relation of Geology to Engineering").

In a description of Ransome's artificial stone (1873) it is stated that the chemicals used were silicate of soda and chloride of calcium. The base was finely sifted sand, to which a small proportion of pulverised stone was added to give the silicate and lime, produced in the manufacture, the necessary closeness of surface for its cementing action.

The report states that the chloride of calcium acts rapidly on the silicate of soda and solidifies the mass.

J. M. LACEY.

London, N.W.8, November 8th.

Modern Trends in Railway Motive Power.*

THE subject which we are to discuss to-night has to do with trends of railway motive power: trends in design, in performance, and in thought. Motive power characteristics depend to a large degree upon the conditions surrounding railway operation. During the past five years we have seen marked changes in these conditions and in the demands for railway service.

Shippers' requirements along with highway competition have forced railway management to alter the character of service given to the public for many years. Huge inventories are no longer necessary; hand-to-mouth buying is the order of the day. Deliveries of materials for manufacturing purposes are now made with sufficient dispatch to ensure prompt completion of finished product. Overnight shipments are now accomplished where days were formerly needed, so that even under the adverse business conditions existing for the past three or four years we find definite departures from previously accepted standards in railway operation, and this is reflected in the design of the motive power that performs the service.

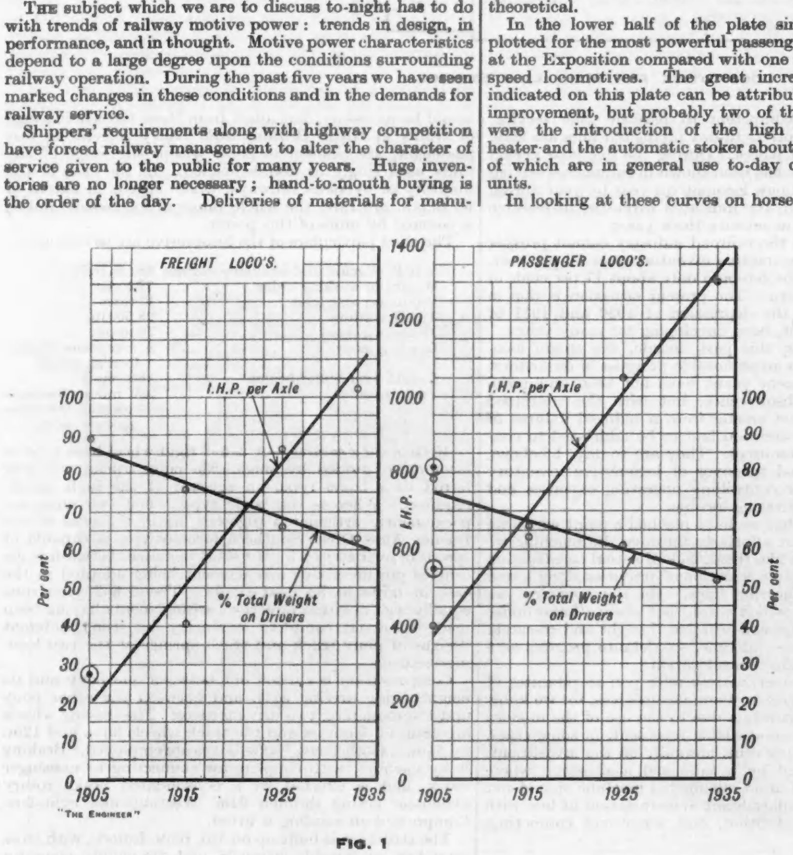

FIG. 1

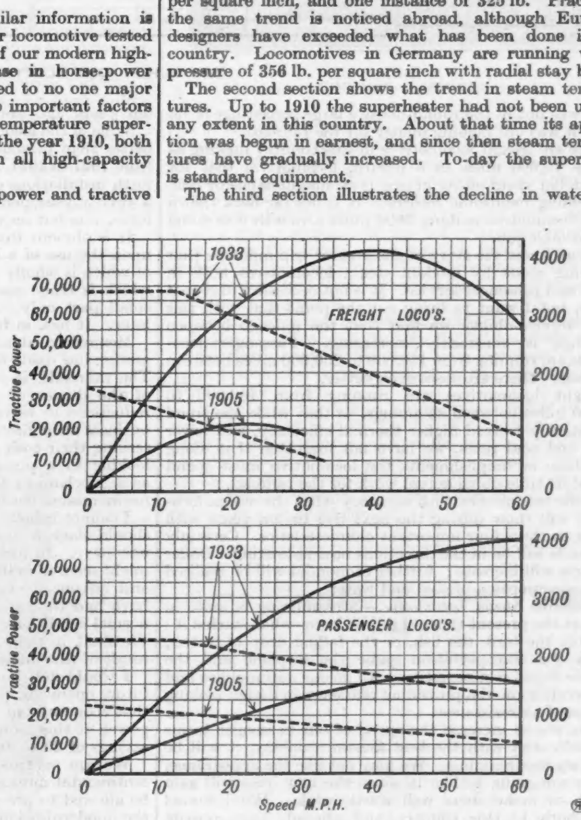

FIG. 2

Steam Locomotive—Indicated Horse-power—Weight Characteristics.—Fig. 1 shows the general trend based upon actual test figures of representative locomotives as to indicated horse-power per axle and percentage of weight on drivers. It does not represent maximum performance entirely—it does show tendencies.

You will observe that freight locomotives averaged about 250 horse-power per axle in the early 1900's, and that to-day we are exceeding 1000 horse-power per axle. Also observe that at the earlier date the percentage of weight on drivers was around 87, while to-day it is approximately 60.

There is a reason for this. As we all know, the freight service of 1905 was slow. Freight locomotives were designed to haul maximum tonnage at low speed. To-day, we still have a limited amount of freight handled in the same manner, but for the past few years the tendency has been toward higher speeds in this service. Since 1923 only the average speed of freight trains in this country has increased 42 per cent. Some of our freight schedules are nearly as fast as those of our passenger trains. This calls for revised ideas as to the characteristics of the freight locomotive. We must have adequate starting tractive effort, but equally important is the capacity of the boiler to maintain these schedules at high speeds. Without increasing to a prohibitive figure individual weight on driving wheels, this enlarged boiler capacity must be carried on trucks.

Individual driving wheel loads have increased materially since 1905, but not to the same percentage as the increase in horse-power. The average weight per driving axle of the freight locomotives tested at the St. Louis Exposition was about 43,000 lb. To-day, it might be considered as being around 60,000 lb. to 65,000 lb., or perhaps a 50 per cent. increase. The horse-power per axle, as you will see from the trend line, has increased during this time close to 300 per cent.

On the other side of the plate you will note that a similar condition exists as to passenger locomotives. The trend line shows an average of about 300 to 400 horse-power per axle in the early 1900's, and to-day we are exceeding 1200 horse-power per axle; likewise, the percentage of weight on driving wheels to total weight is decreased from approximately 75 per cent. to about 55 per cent.

Here I would call your attention to the influence of the "Atlantic" type locomotive as early as 1905. The large circles shown outside of the trend line indicate its relation to the averages of other classes. It had a low percentage of its weight on driving wheels and a correspondingly high boiler capacity. On account of the relatively small number of locomotives of this type in important service to-day, the trend lines have been developed without taking their effect into consideration.

Steam Locomotive—Tractive Power—Indicated Horse-power—Speed Characteristics.—In the upper part of Fig. 2 you will note in full lines the horse-power characteristics of two freight locomotives; in dotted lines, the tractive power characteristics of the same locomotives. The lower lines show the capacity of a "Consolidation" locomotive of 1905; the upper lines represent a modern high-speed freight locomotive with the same number of driving axles. These are actual test curves, not theoretical.

In the lower half of the plate similar information is plotted for the most powerful passenger locomotive tested at the Exposition compared with one of our modern high-speed locomotives. The great increase in horse-power indicated on this plate can be attributed to no one major improvement, but probably two of the important factors were the introduction of the high temperature superheater and the automatic stoker about the year 1910, both of which are in general use to-day on all high-capacity units.

In looking at these curves on horse-power and tractive power characteristics, please bear in mind that the old measuring stick of tractive power does not apply with the force to-day that it did in 1905. At that time the measure of railroad operation was ton-miles; to-day it is ton-miles per hour. Tractive power does not produce ton-miles per hour; horse-power does.

The average tractive power of the most modern fast freight locomotives may be considered at 60,000 lb. to 65,000 lb., or an increase of perhaps 75 per cent. above the "Consolidation" locomotive of 1905 that I have referred to. The horse-power increase, however, is over 250 per cent.

You will find that one of the principal factors in the great improvement in gross ton-miles per train hour is the use of modern high wheel, high horse-power, high-speed freight locomotives—locomotives that have sufficient tractive power to move the tonnage required, but also what their predecessors do not have—sufficient lung power or boiler capacity to give and maintain the horse-power required to perform this service.

Steam Characteristics.—In Fig. 3 we have in diagrammatic form an illustration of the trends from 1905 to the present day in connection with steam characteristics. The first section of the diagram gives you the trend in boiler pressures. I might say at this point that this line is based only on the conventional type of radial stay boiler and does not include anything but simple locomotives. You will note that for several years a boiler pressure of around 200 lb. per square inch was practically standard.

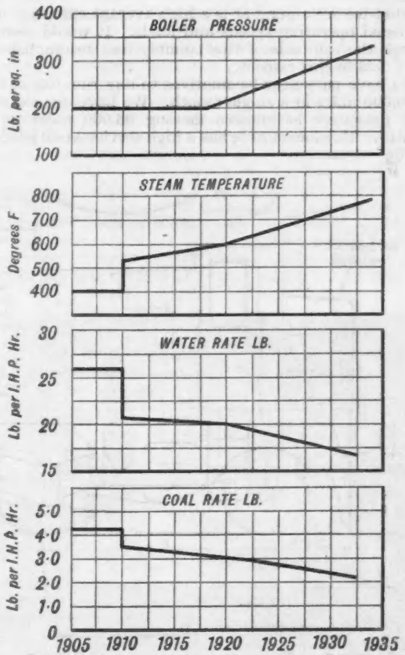

FIG. 3

Along about 1920 the tendency was to increase the pressures, and that tendency has continued until we have a number of locomotives to-day running at 300 lb. pressure per square inch, and one instance of 325 lb. Practically the same trend is noticed abroad, although European designers have exceeded what has been done in this country. Locomotives in Germany are running with a pressure of 356 lb. per square inch with radial stay boilers.

The second section shows the trend in steam temperatures. Up to 1910 the superheater had not been used to any extent in this country. About that time its application was begun in earnest, and since then steam temperatures have gradually increased. To-day the superheater is standard equipment.

The third section illustrates the decline in water rate in pounds per indicated horse-power hour, and the fourth section, the decline in the coal rate. For the saturated steam period up to 1910 these lines have been plotted based upon the averages obtained on the simple locomotives tested at St. Louis.

No trend line is shown for thermal efficiency. It is difficult to do this without opening the door to considerable argument. Steam locomotive thermal efficiencies have increased materially during the past few years up to a maximum of about 14½ per cent. in the condensing locomotive. Thermal efficiency, however, is not the only measure of locomotive performance. A maximum thermal efficiency may be obtained under certain conditions that do not represent the average which the locomotive meets in everyday operation. Thermal efficiency does indicate the possibilities of a design, but its measure should be taken under the conditions which the locomotive has to meet during most of its working time.

---

* From a lecture delivered to the New York Railway Club by Mr. William C. Dickerman, President of the American Locomotive Company, Ltd.

In too many cases maximum thermal efficiencies reported are taken at speeds which do not occur but for a small percentage of the time. Of equal importance is what I might call the service-ability factor. One locomotive giving a high peak thermal efficiency, but very expensive in first cost and unreliable in operation because of its high maintenance, does not make the money for the railroad that another locomotive does with a lower thermal efficiency and with a reasonable first cost, simple in design, low in maintenance, and having a high service-ability factor.

What we are aiming at is a high average efficiency over the usual operating speeds and loads. It would seem as though the railroads of this country had accomplished a great deal in this respect.

We have passenger locomotives to-day running as high as 20,000 miles in a single month. We have one example of a passenger locomotive making 96,000 miles in six months. This locomotive has a high service-ability factor, and it was not in the round-house a large percentage of its time ; it was out making money for the railroad.

There are freight locomotives in this country making as high as 10,000 miles in a month, locomotives that for every dollar spent either in first cost, maintenance or fuel, are yielding handsome returns. It is not far back that a freight locomotive making 3000 miles a month was doing a remarkable job.

You all know the story of the greater trip mileages that are being made by modern steam locomotives both in freight and passenger service. It is not necessary to repeat it here, but I want to bring out the point that with this higher service-ability we find that the mileage between shoppings is constantly increasing. Passenger locomotives are running from 150,000 to 200,000 miles between shoppings—there are cases even better.

Freight locomotives are running from 100,000 to 150,000 miles between shoppings, so that while the trend is constantly toward higher thermal efficiency, and lower steam and coal rates, we have not forgotten that along with these accomplishments the locomotive must spend most of its time doing actual work for the railroad.

No one can predict with accuracy what the steam locomotive will show during the next five to ten years with respect to these four important characteristics. Certainly the trends will be in the directions now indicating. Boiler pressures will increase ; further economies will be realised in the consumption of coal and water.

Streamline Steam Locomotive.—Streamlining is quite in vogue at the present time. I do not know what started it ; probably the bird, the fish, or the falling drop of water ; but in the transportation game the airplane and the dirigible found it a necessity. All of our automobiles and water craft show the prevailing tendency in design looking to reduced air resistance.

If we are to increase the speed of our passenger trains materially and with the best known economy, it will be necessary to streamline. We may not like the appearance, but we are going to like it, since the new lines will gain enough to make them well worth while. Wind tunnel tests, both in this country and abroad, have proven definitely that a streamlined locomotive and train, with proper vestibule connections between cars, and some attention to rear end air currents, will reduce the wind resistance by 20 to 30 per cent.

This is an extremely important item, since it has been demonstrated that an automobile travelling at 60 miles an hour meets with air resistance several times greater than the resistance to forward progress set up by contact of wheels and roadway. It can be shown, too, that reduced air resistance is directly proportional to the degree of streamlining provided.

Here, then, we can readily see a means of reducing the horse-power required to attain high speeds. It is calculated, and I think with a high degree of accuracy, that one of our high-speed passenger locomotives running at 80 miles an hour requires 200 to 300 more horse-power than it would if it were streamlined.

Conclusion.—By way of conclusion, then, it is only meet that I mention the unduly high expense at present revolving around the use of the largest single element in the cost of producing railroad transportation.

Motive power expenses have been unusually high during the past seven or eight years for several reasons. First, the cost of maintenance, per unit of work done by the locomotive, increases steadily with advanced age. Secondly, the thermal efficiency of the modern locomotive has been so greatly improved over that of the power units built prior to ten years ago that large fuel economies are now obtainable by the use of new locomotives, as compared with those now experienced with the existing inventory. And, finally, the character of traffic, particularly freight traffic, has changed radically in the past ten to fifteen years. There is a large and growing demand for high-speed freight service—quite aside from passenger service—which can be met economically and effectively only with motive power having adequate boiler and engine capacity and large driving wheels, all designed to pull heavy loads at high speeds.

Practically none of the locomotives built more than ten years ago are competent to perform this service.

Some of the locomotives to-day plying our lines are little better than museum pieces. During the five-year period from 1927 to 1931, as has been shown in summaries setting forth installations of new locomotives year by year during a twenty-year period, the indicated turnover, in tractive force, was but once in seventy-three years.

It is obvious that the railroad industry cannot prosper upon the use of a locomotive inventory over 50 per cent. of which is wholly obsolete and only about 17 per cent. of which is truly modern. The present situation is due in small part only to the depression of 1930 and 1931 or later. It has, in fact, been developing for many years.

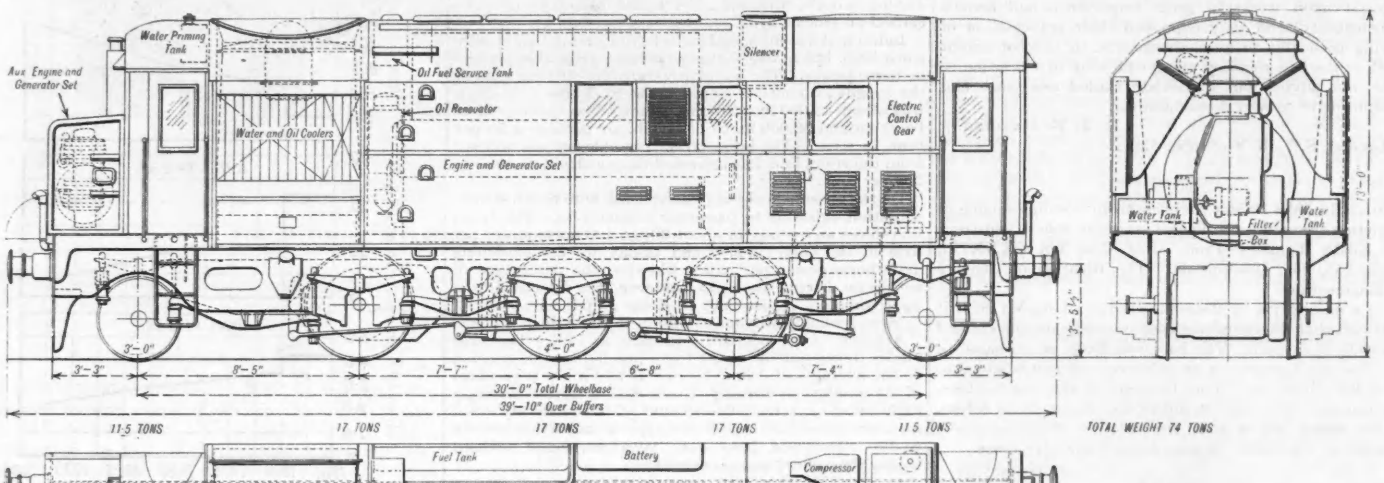
Meanwhile, during this past decade, the steam locomotive has made the most notable progress in its history. The railroads, in recent years, have not been unmindful of the degree of obsolescence, but with the continued reductions in revenue arising from a reduced volume of business their first attention had to be addressed to conserving their cash resources. They are to-day, I believe, looking to a planned turnover of locomotive inventory as a mechanism for controlling operating expenses and for increasing net operating income.

I cannot believe that we have reached a point where we should slacken in our efforts to improve the machine we now have. In times like these, lack of actual construction might seem to indicate a cessation of activities along sound and advanced engineering lines. On the contrary, we have had the time, which we do not always have under normal conditions, for constructive thought and research. We shall, in the course of time, see definite progress as a result of this intensified consideration.

I would not, however, merely refer you to promises of future operating values in steam locomotives, for we know that economies in operation due to the use of the modern power at this moment available represent, in some cases, savings of 20 to 40 per cent. annually on the investment.

We are confronted by a time and a situation where sentimental interest in an out-moded machine should not be allowed to prevent railroad modernisation in line with the modernisation of other, and sometimes competing, industries.

It appears from the latest returns that Great Britain maintains a lead over all other countries as regards the export of aircraft. In 1930–31–32 the total value of British exports exceeded that of the United States by £1,180,482. In 1930 British exports led by 68 per cent., in 1931 by 79½ per cent., and in 1932 by 60 per cent. In 1932 the exports were valued at £1,751,303. The total for the three years was £5,652,618.



880 B.H.P. OIL-ELECTRIC LOCOMOTIVE FOR MAIN LINE SERVICE

L.N.E.R. Main Line Oil-Electric Locomotive.

The main line oil-electric locomotive which is in the next few weeks going into service on the Newcastle-Berwick section of the London and North-Eastern Railway, is claimed to represent a distinctly further stage in the progress of oil-electric traction manufacture in Great Britain. Although not the most powerful yet built, it is intended for use, when required, with one or more similar units—a feature not incorporated in the larger individual engines so far constructed—and therefore is a step towards the utilisation of greater powers than the heaviest existing steam locomotives possess. Two similar units are under construction at Newcastle by Sir W. G. Armstrong Whitworth and Co., Ltd.

It is claimed that as regards flexibility and versatility, the new locomotive is unique. The patented electric transmission permits full utilisation of the power of the oil engine at speeds between 6 and 60 miles per hour. The locomotive is therefore suitable for heavy goods trains scheduled at 20 m.p.h. average speed and fast passenger trains running at a maximum of 70 m.p.h. Trains such as the 600-ton Anglo-Scottish expresses are beyond the ability of two such units, and higher-powered engines would be necessary, but apart from these the whole range of trains in Great Britain, from heavy mineral to fast passenger, are claimed to come within the scope of the units used singly or double-headed. In the case of the majority of overseas railways, where speeds in excess of 60 m.p.h. are rare, the whole range of locomotive duties is covered by units of this power.

The chief particulars of the locomotive are as follows :—

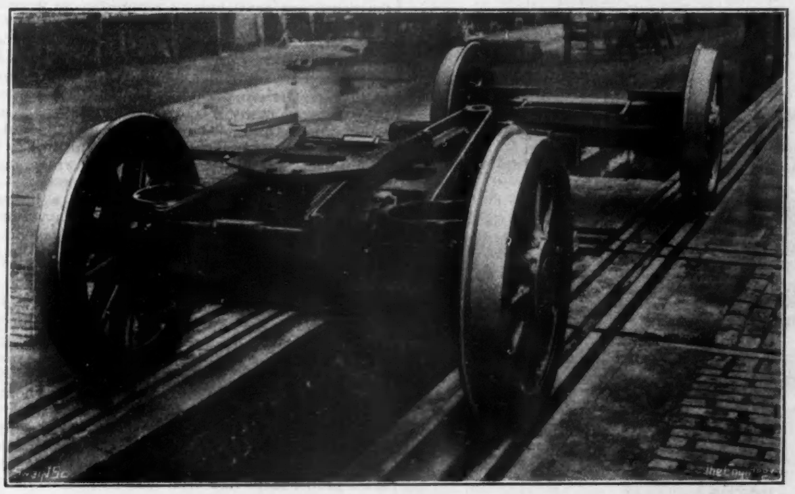
B.H.P. of main and auxiliary engines	880 B.H.P.
Weight in working order	72 tons
Maximum axle load	17 tons
Tractive effort	28,500 lb.
Maximum speed	70 m.p.h.
Loading gauge	A composite British loading gauge
Length over buffer beams	36ft. 6in.
Fuel capacity	900 miles passenger working, 500 miles goods working

Mechanical Features.—A 2–6–2 rigid wheel base type of locomotive, guided by single-axle pony trucks, was preferred to a bogie type, on account of the high speeds required. Whereas the bogie type, when two units are permanently articulated together, as in the case of the Buenos Aires Great Southern locomotives, is capable of speeds of over 80 m.p.h., the short distances between bogie centres precludes this arrangement being adopted in the case of units to be used singly. The 2–6–2 type runs equally well in either direction, arrangements having been made to avoid complete symmetry by using different designs of pony truck and truck springs at the two locomotive ends.

Compensation is carried out between one pony and its neighbouring driving axle, and between the other pony and the remaining two driving axles. The driving wheels are 48in. in diameter and the truck wheels 36in. and 12in. by 5½in. "Isothermos" axle-boxes are employed. Braking is by vacuum, with couplers for connecting to passenger stock, and is effected by a consolidated brake rotary exhauster acting through 24in. Westinghouse cylinders. Compressed air sanding is fitted.

The structure is built up on 1in. plate frames, with cross stretchers at suitable intervals, and the engine generator set is supported upon what is virtually a three-point support. The body is formed of steel sections and sheets in which welding has been adopted to a great extent. Triplex safety glass is employed for the driver's windows, and Arctic glass for the engine-room lights. A section of the roof is removable for the purpose of lifting out the main engine set during overhauls. The auxiliary engine is accommodated under a bonnet at one end of the vehicle, the bonnet being hinged and easily lifted in the same manner as the bonnet of a lorry engine. Ventilation of the interior is ensured by partitioning off the engine from the generator, and allowing the generator to draw in cool air through louvres and then to discharge it into the engine-room proper, from which it escapes through the roof ventilators.

Engine.—The engine is a British-built eight-cylinder Armstrong-Sulzer engine of the same size as that used on the Paris Ceinture Railway. Two cast iron cylinder blocks are built up on a welded steel crank chamber, which forms with the circular extension of the generator, what is virtually a single tubular unit comprising engine and generator, which can be lifted out of the locomotive, and which, when resting on an elastic seating, provides the three-point support previously mentioned. Separate cylinder heads, each with valves in removable cages, and separate fuel pumps and valve gear are provided for each cylinder. Full power is developed at 700 r.p.m. and two reduced speeds are provided for medium power and for idling, though with the arrangements made for continuous easy starting of the main engine, the latter speed is only used to a limited extent when in regular service.



THE SINGLE-AXLE PONY TRUCKS

The cylinder liners are of special cast iron, the pistons of forged aluminium alloy, and the connecting-rods are chrome nickel steel forgings. Cooling is effected by a direct driven pump circulating water through Serck radiator elements. Cooling elements are also provided for the lubricating oil. As in all Armstrong Whitworth locomotives of large power, these elements are arranged on each side of the locomotive with ducts leading up to a single fan placed in the roof. In this case a Davidson "Aeroto" fan, motor-driven and thermostatically controlled, is employed. Fuel tanks are arranged on each side of the engine-room, and are of sufficient capacity for British requirements, though larger tanks can be incorporated for overseas needs where 1000 miles between re-fuelling may be necessary.

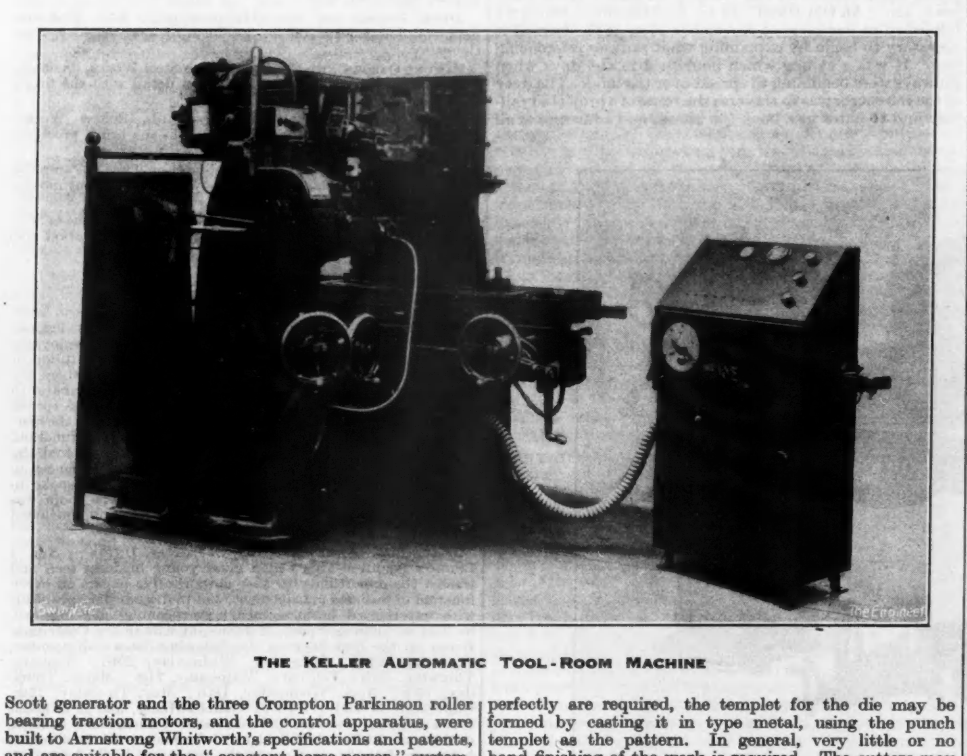
An interesting feature is the fitting of a streamline lubricating oil renovator which obviates the necessity of drawing off oil, cleansing it in renovators in the running sheds, and returning it to the locomotive. This filter is in constant use, and the make-up oil occasionally added amounts on the average only to 1 per cent. of the fuel oil used by the engine.

Electrical Transmission and Control.—The main Laurence Scott generator and the three Crompton Parkinson roller bearing traction motors, and the control apparatus, were built to Armstrong Whitworth's specifications and patents, and are suitable for the "constant horse-power" system. This control is entirely self-regulating, and the driver's duties are confined to attention to the road, and manipulation of the single controller handle and of the brake valve. It is stated that on the full power notch of the controller the output of the engine is automatically regulated within plus or minus 3½ per cent. of the nominal horse-power. When two units are coupled together, no men are carried on the second locomotive. A dead man's device is fitted, and where desirable it may take the form of the Armstrong Whitworth delayed action device, which allows the driver to leave his controller to accept tokens in single-line working.

Tests with passenger and goods trains of varying loads and speeds have been made by courtesy of the London and North-Eastern Railway Company on the Newcastle–Edinburgh line and on the Carlisle route, and are stated to have demonstrated the suitability of the locomotive for the regular service upon which it is now entering.

Automatic Tool-Room Machine.

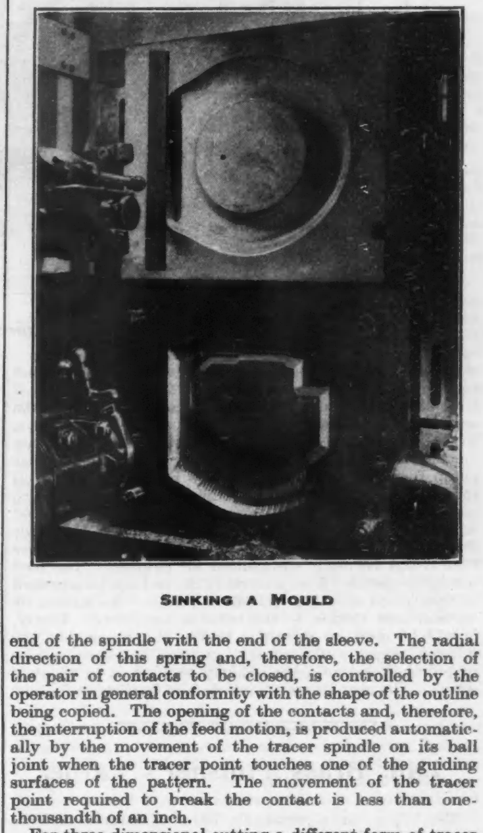
AT a recent demonstration of machine tools for producing moulds for plastic materials, which was given at the Coventry works of Alfred Herbert, Ltd., the Keller automatic tool-room machine illustrated herewith formed a conspicuous exhibit. This machine is made by the Keller Mechanical Engineering Corporation of Brooklyn, N.Y.—a branch of the Pratt and Whitney Company—and operates on the milling principle, the cutter being guided in the required path by means of a tracer passing over a templet or master form. In our second engraving the machine is shown cutting the die for a lavatory seat, the master form in this case being a plaster mould. In this and similar applications a three-dimensional movement of the cutter is required. The machine can, however, equally well be set to cut with a two-dimensional movement of the tool, as, for example, in contouring a stripping die, such as that used for removing the fin from a drop forging. For three-dimensional work, the master form may be of wood, cement, plaster, or other material, or may be a finished tool, the shape and dimensions of which are to be reproduced in the form of a mould. For two-dimensional work the templet may be of light sheet brass or zinc. If a punch and die which must match perfectly are required, the templet for the die may be formed by casting it in type metal, using the punch templet as the pattern. In general, very little or no hand finishing of the work is required. The cutters may range from 0·036in. to 4in. in diameter.



THE KELLER AUTOMATIC TOOL-ROOM MACHINE

Of the three movements of the tool relatively to the work, two are provided by a longitudinal and a transverse sliding movement of the work table. The third is given by a vertical movement of the cutter head on its column. The work is secured to the vertical face of a fixture bolted to the table and supporting a similar fixture to the face of which the pattern to be copied is attached. The head sliding vertically on the column and carrying the cutter spindle also carries the tracer spindle, the point of which engages with the pattern. The upper pattern-carrying fixture is adjustable horizontally, with respect to the lower work-carrying fixture to within fine limits. A correspondingly fine adjustment is provided for the vertical distance between the cutter and the tracer spindles.

Each of the three lead screws providing the three movements above referred to is driven by an individual variable-speed motor through a gear-box containing a pair of magnetic clutches. These motors communicate their respective motions in one direction or the other, according to which of the magnetic clutches is engaged. The engagement or disengagement of the clutches is, in turn, governed by electrical contacts established by the mechanical movement of the tracer when its point experiences pressure from the pattern or templet. For contouring or two-dimensional work, the tracer consists of a sleeve within which a spindle is mounted on a ball joint near the front or work end of the sleeve. Within the bore of the sleeve at the rear end there are four electrical contacts, two of which, lying on a vertical diameter, control the up and down motion supplied by the motor associated with the vertical lead screw, while the other two, lying on a horizontal diameter, control the sideways motion supplied by the motor associated with the horizontal lead screw. Corresponding contacts are carried on the rear end of the tracer spindle. The contacts are closed by means of a spring connecting the end of the spindle with the end of the sleeve. The radial direction of this spring and, therefore, the selection of the pair of contacts to be closed, is controlled by the operator in general conformity with the shape of the outline being copied. The opening of the contacts and, therefore, the interruption of the feed motion, is produced automatically by the movement of the tracer spindle on its ball joint when the tracer point touches one of the guiding surfaces of the pattern. The movement of the tracer point required to break the contact is less than one-thousandth of an inch.



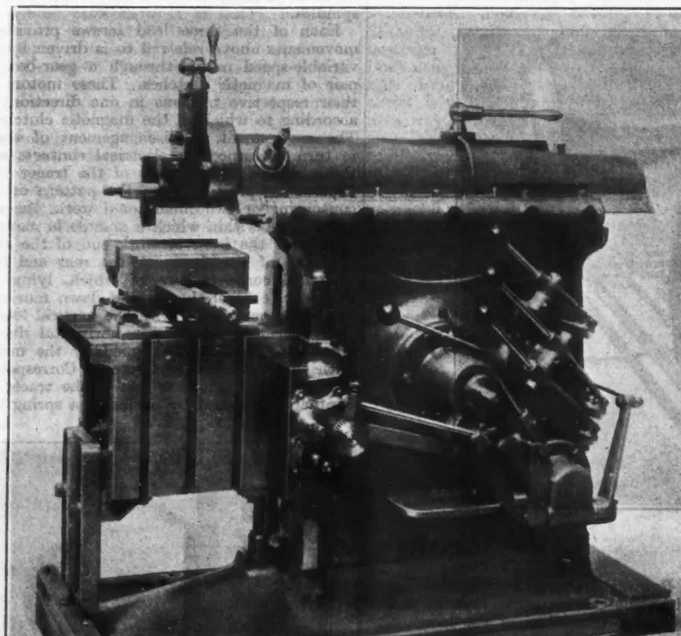
SINKING A MOULD

For three-dimensional cutting a different form of tracer is employed. This tracer follows the outline of the pattern automatically and, at the same time, continuously seeks contact with the pattern surface in the direction of the depth of the mould.

The cutter is driven by a 3 horse-power motor at speeds ranging from 80 to 3600 r.p.m. For very small milling cutters a super-high-speed spindle driven by a self-contained variable-speed motor can be fitted. With this spindle speeds of from 8000 to 11,000 r.p.m. are obtainable. All the electric controls of the machine are centralised at a separate cabinet.

The "General Purpose" Crank Shaper.

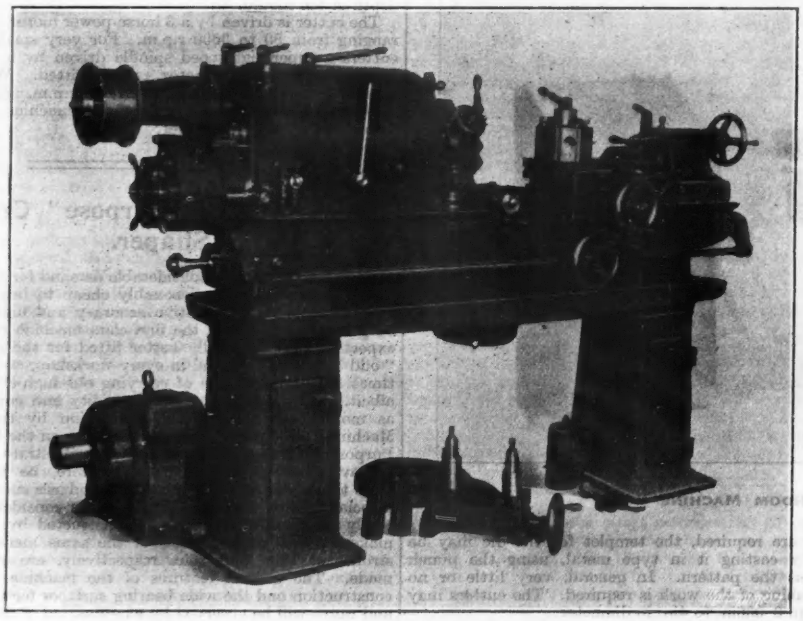
THERE is probably a considerable demand for high-class tools of various kinds reasonably cheap to buy. While in such tools the superlative accuracy and high rate of output associated with the first-class machine cannot be expected, they are really better fitted for the numerous "odd" jobs to be found in every workshop, and in busy times are quite capable of carrying out high-class work, albeit, perhaps, not with such rapidity and convenience as more costly tools. The production by the Butler Machine Tool Company, Ltd., of Halifax, of the "General Purpose" 18in. stroke crank shaper illustrated by the engraving on page 492 will, therefore, be welcomed, since this machine, while made to standards such as those associated with the name of Butler, is considerably less costly than other similar tools constructed by the same makers. Two other models of the same machine with strokes of 12in. and 26in. respectively, are also being made. The general features of the machine—its rigid construction and the wide bearing surfaces for the saddle and ram—will be observed by examination of the engraving. At the back fast and loose pulleys are mounted, the latter on ball bearings for economy when the machine is idle. In the fast pulley there is a quick-acting brake so arranged that the operator may stop the ram at any point in its stroke. Eight changes of speed from 10 to 100 cycles per minute are obtainable from gears mounted within the body and operated by ball-ended levers at the front of the machine. All the shafts within the gear-box are mounted on ball bearings. The stroke wheel is made of special cast iron, and is of single helical construction, while the crank pin and block are machined in one piece from a steel forging. The crank lever also is made of special cast iron, and it is heavily ribbed to withstand rigidly the stresses thrown upon it. It is driven by a large phosphor-bronze die. Length and position of stroke are adjustable while the machine is in motion. Nowadays, special attention is devoted to lubrication in all high-class machine tools, and this shaper is no exception. A gear pump installed in the base of the machine delivers oil through copper pipes to the link motion, ram slides, crank pin, and gearing. The oil, moreover, is filtered on both suction and delivery sides of the pump, the latter filter being so arranged on an extension of the base that it can be easily dismantled for cleaning. The feed motion is operated from a slotted disc, and can be arranged to take place at either end of the stroke. An automatic vertical feed motion to the table is also fitted. Lastly, it will be seen by reference to the engraving that the control levers, while suitably grouped together, are so placed that no confusion is likely to arise as to which is which. The gear-levers are interlocked to prevent fouling.



THE "GENERAL PURPOSE" CRANK SHAPER

7½in. Brass Finisher's Lathe.

THE 7½in. brass finisher's lathe illustrated by the accompanying engraving was made by the Selson Machine Tool Company, Ltd., of 23, Abbey House, Victoria-street, and has just been shipped abroad. It is directly driven by an electric motor mounted on an extension of the base behind the headstock, and twelve changes of speed, ranging from 25 to 500 r.p.m., are obtainable from the gear-box in the headstock. The hollow spindle has a bore of 1⅝in. The bed is 5ft. 9in. long, admitting work 2ft. 4in. long between centres. Built into the bed of the lathe there is a gear-box which gives three rates of automatic sliding feed to the saddle. Four copy screws are arranged at the tail end of the headstock, and any one of these can be readily located to agree with one of the mating nuts, which are mounted on an arm attached to a sliding shaft running the whole length of the machine behind the bed. Attached to the shaft is a chasing arm, which, on the movement of a small lever, hinges upwards or downwards. At the same time the sliding shaft is turned and the copy screw nut disengaged or engaged with the copy screw. By the use of this mechanism, much time is saved in the cutting of screws, &c. A cutting-off rest with front and rear tool holders forms part of the equipment.



7½ IN. BRASS FINISHER'S LATHE

SIXTY YEARS AGO.

How many of our readers, we wonder, could define the occupation known as "railway referencing." We do not know whether railway referencers still exist as such, but if they do they can have little opportunity nowadays of plying their calling, in this country at least. Even sixty years ago "An Old Hand" in his reminiscences, which we published in our issue of November 21st, 1873, deemed it necessary to begin by explaining what railway referencing was. It was a calling which flourished in the days when railways were beginning to spread over the land. The duty of the referencer was to traverse the route of a projected railway and to enter in a book the names and addresses of all parties interested as owners, occupiers, or lessees of the land over which the railway was to pass, and of such persons in the neighbourhood of the line on whom it would be necessary to serve notices intimating the intention of the promoters to apply to Parliament for authority to construct the railway. The book so compiled was known as "The Book of Reference to the Plans of the Proposed Railway." The referencers used to go forth in swarms towards the end of October in order that the plans and their books of reference might be completed and ready for deposition on November 30th, the day appointed by Parliament for such deposition in connection with applications for Bills to be considered in the ensuing session. Of necessity, our contributor's reminiscences were more of a personal than of a technical nature. They provide, however, an illuminating, not to say entertaining, picture of England during the railway mania of 1844 and 1845, and the years immediately preceding and following that highly speculative period. The old-time referencer was drawn from many occupations. Half-pay army and naval officers, and decayed, idle, or improvident members of the other professions flocked like vultures to the work, and in the waste and extravagance which marked the days of the mania they picked up good, if temporary, remuneration. Attired sometimes like a lifeguardsman, sometimes like a gamekeeper on holiday, they became the little magnates of the village inns, and, spending money freely to acquire the information which they sought, were objects of reverential attention from the rustic populace. Frequently they had to face opposition and to resort to guile to obtain their ends. There were owners of land who did not want the railways to encroach upon their properties, and there were post-boys who felt that the coming of the railway would deprive them of their occupations. Our contributor had some harsh and uncomplimentary things to say about the British farmer with whom naturally he was brought during the course of his work into close contact. He openly expressed his preference for rat catchers and poachers, and acknowledged that in his time they had provided him with much invaluable information, after proper steps had been taken to overcome their diffidence and shyness. Railway referencing undoubtedly had its excitements and its attractions. The period during which it flourished was one not lacking in romance and colour, for it marked the departure of an old and the beginning of a new order. It seems strange that so far as we know only one author, the late Stanley Weyman, has chosen it for the background of a historical novel.

BOOKS OF REFERENCE.

*The British Waterworks Year Book and Directory, with Statistical Tables,*1932–33. General Editor, G. P. Warner Terry. London: The British Waterworks Association, Grand Buildings, Trafalgar-square, S.W.1. Price £1 1s. to members, £1 11s. 6d. to non-members of the Association.—This edition, the fourth, is considerably larger than its predecessors, and contains full, up-to-date details of 1486 water undertakings, as compared with 871 in the 1931 issue of the book. The lay-out is the same as in the past, the first part comprising a Directory giving in alphabetical order the names of undertakings and full particulars concerning them. Section II. consists of some 156 pages of statistical tables and Section III. contains a large amount of miscellaneous information. The usefulness of this book of reference has been proved time and again, and we are sure the new issue will be found of equal, if not greater, value than its predecessors.

CATALOGUES.

PETTERS Ltd., Yeovil.—Details of the "Atomic" Diesel oil engine, stationary type.

DAVID BROWN AND SONS (HUDDERSFIELD), Ltd., Huddersfield.—A detailed list of the products of the Keighley Gear Company.

SAMUEL OSBORN AND Co., Ltd., Clyde Steel Works, Sheffield. —A book of some 400 pages dealing in detail with the firm's products.

FRANCOIS CEMENTATION COMPANY, Ltd., Benley Works, Doncaster.—A loose-leaf reference book of the firm's processes and activities.

A. REYROLLE AND Co., Ltd., Hebburn-on-Tyne.—Pamphlet No. 829, describing the "Castle" R-type direct-current motors and generators.

STURTEVANT ENGINEERING COMPANY, Ltd., 147, Queen Victoria-street, E.C.4.—Publication No. 1374 on air filtration and conditioning plant.

THE INSTITUTION OF AUTOMOBILE ENGINEERS.—Last Friday, November 10th, there was held one of the most enjoyable annual functions of the year—the dinner of the Institution of Automobile Engineers. Whether it is the fact that there are no "regular" speeches, or that there is a dance and cabaret to follow the dinner, the affair has for some reason a special character of its own, not unconnected perhaps with the personality of Mr. Basil Joy, the secretary. At this latest function, which was held at the Park-lane Hotel, Earl Howe told the assembly of members and guests some of his experiences in road racing and elsewhere, and the President also spoke in lighter vein. There were no other speeches. The room was subsequently cleared for dancing, and the function concluded eventually in the early hours of Saturday morning.

INDUSTRIAL ADMINISTRATION STUDENTS UNION: No. 1 LONDON GROUP.—This Union gives young business men and women the opportunity to hear authoritative papers on every function of business management, and to discuss their problems with experienced business men. Forthcoming meetings will be held at Thames House, Millbank, at 6.30 in the Conference Room on the first floor on the following dates:—November, Thursday, 23rd; December, Wednesday, 20th; January, Thursday, 18th; February, Wednesday, 21st; March, Thursday, 15th; April, Wednesday, 18th; May, Thursday, 17th. Omnibuses 77 and 177 go to Thames House, and it is about seven minutes' walk from Westminster Underground Station, or the trams at Vauxhall Bridge. Refreshments can be obtained before or after the meetings at the restaurant in the basement. Particulars of membership may be obtained from the Hon. Secretary, B. W. Galvin Wright, Imperial Chemical House, Millbank, S.W.1.

Railway and Road Matters.

The L.N.E.R. reports that a contract has been placed with the Westinghouse Brake and Saxby Signal Company, Ltd., for the installation of colour light signalling between Seven Sisters and Enfield Town.

The unilateral system for waiting vehicles is about to be officially tried in Jermyn-street. This is an arrangement whereby vehicles may on certain days stand on only one side of the street. They may stand on the south side on Mondays, Wednesdays, and Fridays, and on the north side on the other three days. Derby is one of the boroughs where this arrangement has been in successful operation for some time.

The number of passenger-carrying vehicles that are lighted by gas is gradually being reduced. The Railway Returns for the year 1932 show that the percentage lighted by gas out of the total number of carriages was reduced from 37½ at the end of 1931 to 34½ at the close of 1932. The percentage of those lighted electrically correspondingly rose from 62 to 65. All the 1377 passenger-carrying vehicles built or purchased during 1932 were electrically lighted.

We are prompted to follow up the paragraph herein on November 3rd as to the bell on the signal-box at Hebden Bridge by the remark that the use of a bell for the purposes named is quite irregular. There was a time when that was part of the equipment of a signal-box, but for a good fifty years that has not been the practice of any leading British railway. The companies did not consider it their business to warn passengers of the approach of trains, and, further, the abolition of the bell secured greater punctuality.

Herein on January 20th last we recorded that Mr. John Miller, the engineer of the North-Eastern Area, London and North-Eastern Railway, had found short fishplates, with two holes, so satisfactory that they had been adopted as the standard on that area instead of the 18in. four-hole plate. The Great Western is now experimenting in the same direction, and Mr. A. S. Quatermaine, that company's assistant chief engineer, at the G.W. Debating Society on October 19th, spoke of the successful experimental adoption of a 10in. two-bolt fishplate, instead of one of 18in. with four bolts; if, after further tests, the joint was found satisfactory for standard use, an economy of £5000 per annum would accrue from the change.

The Institution of Railway Signal Engineers, on the evening of Wednesday, November 8th, discussed the question of the possibilities of danger side failures of track circuits, caused by sand, dirt, grease, &c., on the rails. These features are liable to impair the contact between wheel and rail and to cause a vehicle that may occupy a section or be standing foul not to short circuit the track battery and thus allow the protecting signal to remain at "clear"—which is a failure on the danger side. This matter was mentioned by Lieut.-Colonel Mount in his annual report on the accidents of 1931, when he said that there had been two such accidents—neither of them serious—through such failures. He added that the matter was receiving the attention of the railway companies. The discussions on November 8th indicated that the fault did not lie with the signalling department, and that the chief mechanical engineers were seeking means whereby the locomotive, after having deposited sand on the rail, blew it or washed it off after the driving wheels had passed.

Following what we said on October 27th as to the fewer companies, as represented by their locomotives, using Carlisle and York, we might also refer to Peterborough. There are two stations in the city—what was the Great Northern is now the North Station, whilst the former Great Eastern is Peterborough South. Until the grouping of the companies, five railways ran into Peterborough—the Great Northern, Great Eastern, Midland, London and North-Western, and Midland and Great Northern Joint. The last-named is still there and under the same name, and, in addition, the London and North-Eastern and London, Midland and Scottish. Although the Great Northern was always the principal company, it did not arrive there until the line was opened from Boston on October 17th, 1848. The Midland entered Peterborough from Stamford on October 2nd, 1846, and then joined the London and North-Western line from Northampton, which was opened on June 2nd, 1845. The last-named did not, however, enter the present North Station. A little-known fact is that in running between the Great Northern and Great Eastern stations a length of the Midland had to be traversed, and thus to-day the London and North-Eastern, in order to get from the eastern to the northern section, has to pass over 34 chains of London, Midland and Scottish metals.

One of the benefits secured by the Light Railways Act, 1896, is that gates need not necessarily be provided at the level crossings of the railway over public roads. Safety is secured by speed limits and whistle boards on the railway and conspicuous warning boards on the highway. That is done at some of the crossings on the Totton, Hythe, and Fawley Light Railway on the Southern, and one such was at Frost-lane, where there was a collision, without fatal results, between a train and a motor car on November 15th, 1926. That mishap was investigated by Colonel Mount, whose report was reviewed by us on April 15th, 1927. Another crossing without gates is at Jacob's Gutter-lane, where a more serious accident occurred on July 26th. On that occasion the driver of a motor lorry was killed, and the coroner's jury who inquired into the facts considered that the train had been handled negligently, and that there should be gates. Colonel Anderson, who investigated the case on behalf of the Ministry of Transport, however, found that there was no negligence by the trainmen, and was of opinion that the evidence indicated conclusively that the accident was entirely due to the rash driving of the motor lorry. That officer also said that the accident occurred on the side of the level crossing where the view of lorry and train was best, and, in itself, constituted no justification for requiring the erection of gates. Conditions on the other side of the crossing had, though, changed, and the road-user's view of the railway had deteriorated. Colonel Anderson recommended that the local authorities and the Southern Railway should consider the provision of light signals to give a warning on the roadway when a train was approaching.

Notes and Memoranda.

A society for the preservation of old Sheffield tools and machinery has been formed. The Hon. Secretary is Mr. W. H. Bolton, of the Applied Science Department, Sheffield University.

The latest report issued by the National Federation of Iron and Steel Manufacturers shows that the output of pig iron in October was 373,300 tons, against 359,700 tons in September and 275,600 tons in October, 1932. The output of steel ingots and castings was 668,300 tons, which was practically the same as in September, but represented an increase of 228,500 tons compared with October, 1932.

An excerpt from the *Edgar Allen News* :—"The large and ever-increasing use of alloy in case-hardening steels in high-grade gear work has made the heat treatment department of any gear factory one of its most important sections, if not the most important. Accurate and costly machining operations are entirely wasted if the material does not possess adequate physical properties for the duties, and these in many cases nowadays can only be obtained by most careful attention to heat treatment."

A new type of flame, known as the diffusion flame, has been devised for forging operations. According to Mr. Henry O. Loebell, vice-president of the Combustion Utilities Company, New York, this new burning method provides alternate layers of gas and air slowly flowing through a furnace so that combustion takes place only at the zones where air and gas meet. When in operation, an unburned gas blanket flows over the heated steel, preventing it from forming scale, and the flame is said to enable work to be heated to the forging temperature at unheard-of speeds.

It appears from experiments carried out for the Safety in Mines Research Board by Messrs. T. N. Mason and R. V. Wheeler, on dusting in coal mines for the reduction of explosions, that as compared with the shale dusts commonly used, limestone and gypsum have been found markedly more effective in rendering coal dust incapable of propagating flame. A warning is given, however, that when assessing the value of an incombustible dust for treating coal dust on mine roadways, the ease with which it can be dispersed as a cloud, more particularly after it has been exposed for some time to the atmosphere of the mine, must be considered. In this respect gypsum is more liable to cake than either limestone or shale dust.

Some experiments carried out by Mr. R. L. Dowdell, and communicated to the American Society for Steel Treating, on the ageing of miscellaneous steels when treated for permanent magnets, show that tempering at 100 deg. Cent. for 12 hours, followed by tempering in the magnetised state until about 5 per cent. of magnetic induction is lost, followed by sacrificing 5 per cent. more by a reversed demagnetising field, gave the greatest stability of any of the treatments used. This treatment indicates that both hardening and magnetic strains should be partially removed in order to stabilise permanent magnets regardless of their composition. The several tables included give the treatment and ageing characteristics over a period of about ten years.

A pamphlet has been issued by the British Aluminium Company, Ltd., on the M.B.V. process for the surface treatment of aluminium and its alloys, by Dr. G. Eckert, which was one of the prize-winning essays in the 1932 International Aluminium Competition. The bath used in the M.B.V. process is composed of an aqueous solution of anhydrous sodium carbonate and anhydrous sodium chromate at a temperature of 90–100 deg. Cent. The colour of the M.B.V. film varies from light to dark grey, and while mechanical resistance of the film is not exceptionally high, it will resist the action of ordinary bristle brushes. A secondary treatment, which consists in maintaining the part concerned for 15 min. in a 3–5 per cent. solution of sodium silicate at 90 deg. Cent., followed by rinsing in water, increases the hardness of the coating appreciably and also improves its resistance to corrosive action. The M.B.V. film is very adherent and cannot be detached by folding, rolling or by pressure as it possesses a high elasticity.

It appears from a note by Major C. C. Turner, in the *Daily Telegraph*, that while some of our Continental rivals may be embarking on some spectacular aerial voyages, our own efforts in this direction are noteworthy, although they may not receive so much public attention. Thus since March, 1926, the R.A.F. has carried out thirty extensive formation cruises of three or more aircraft, the route aggregate being 250,000 miles. Many of the R.A.F. formation flights are periodical and by way of routine. Thus there have been six from Cairo to the Cape and back, with Army co-operation exercises *en route*, and others from Cairo to Somaliland, East Africa, and Rhodesia. Before the present cruise there have been four to West Africa. A remarkable circumstance of these British cruises has been their comparative freedom from serious mishap. One fatal accident has occurred during these operations, resulting in two deaths. The R.A.F. flies some 25,000,000 machine miles in a year, and it "polices" more than 1,000,000 square miles of the world.

The Annual Report of the Building Research Board, Department of Scientific and Industrial Research, shows that by far the largest number of failures which are reported to the Station are concerned with plasters and renderings. Hundreds of specimens of plaster have been submitted for examination, and in the majority of cases it could not be said that the materials were defective. "It is probably safe to assume," says the Report, "that haste is the most important of the changed conditions which give rise to these failures in lime plaster work; undercoats are not allowed sufficient time to carbonate and dry thoroughly before applying finishing coats; manipulation is a more perfunctory matter than it was traditionally; fresh plaster is more liable to disturbance; poorly seasoned timber may warp and shrink; electricians, gas-fitters, and pipe fitters may be expected to work above them at a time when plaster ceilings are very sensitive to vibrations. As a result of these tendencies, it is considered that the very low strength of a lime plaster ceiling on lathing should be augmented by an addition of a suitable material having definite hydraulic setting properties."

Miscellanea.

The old Reliance Gold Mine at Penhalonga, Rhodesia, is to be re-opened.

Some large deposits of molybdenum ores are said to have been found in the Rokko hills, near Takarazuka, Japan.

The Blue Star Line has decided to order two 12,000-ton ships equipped with refrigeration apparatus for trade on the New Zealand route.

Two more blast-furnaces have been blown in by Dorman Long and Co., Middlesbrough, one at Cleveland and the other at the Acklam works.

Paddington's new giant timetable clock, fully described in The Engineer of September 29th, 1933, which is claimed to be the biggest moving figure clock in the world, started work on Wednesday, November 8th.

What is claimed to be the largest land aeroplane in the world, the "K 7," has been completed at the Kharkov factory under the direction of the engineer Kalinin. According to the *Manchester Guardian*, it is an all-steel model, made entirely of Russian material.

Materials of construction, to use these terms in their fullest significance, will be demonstrated and explained in the language of their latest developments at the Fourteenth Exposition of Chemical Industries, which is to be held at Grand Central Palace, New York, December 4th to 9th, 1933.

The electric generators for the Boulder Dam powerhouse in America will be of 82,500 kVA each at unity power factor, three-phase, and are designed for 50-cycle generation at 150 r.p.m., and 13,800 volts or 60-cycle generation at 180 r.p.m. and 16,500 volts. The turbines will work under a head of from 450ft. to 560ft.

There is a brief account in the *South African Mining and Engineering Journal* of the efforts of a young Rhodesian. Michael MacDonald is only seventeen years old, but he works a gold mine alone, with the help of a dozen natives, and is getting ore assaying 9 dwt. per ton. He is putting in a battery of drop stamps to work the ore.

It is reported that the Sorima Company, which has been responsible for the salvage of the gold in the wreck of the "Egypt," off the coast of France, proposes to carry out experiments in diving to depths greater than those reached in the case of the "Egypt." These experiments will be conducted in combination with trials of artificial lighting in the Mediterranean.

Some indication of the state of trade in the Birmingham district may be gathered from the fact that the Austin Motor Company, which is now turning out from 1600 to 1800 cars a week, is extending its premises. A new factory for making motor tire valves has also been established in the district by an American firm, while a number of other existing factories are being extended.

Prior to the war and over a period of five years only ten trucks and 450 light cars were assembled in Russia. During the five years 1928–32 the U.S.S.R. has built up an automobile industry which has already turned out nearly 58,000 cars.. On August 16th, the Stalin Auto Works in Moscow had turned out 30,000 cars. One car in every ten minutes is now being produced at these works.

A new gasholder, according to the *Iron and Coal Trades Review*, is being erected at the Neunkirchen Ironworks in place of the waterless gasholder which was destroyed by the explosion in February last. The new holder is to be of the standard water type, and will have a capacity of 30,000 cubic metres; a new position has been chosen near the Bauernhaus steel works. A smaller gasholder of 3000 cubic metres is to be erected for the coking plant.

The Chinese Government is said to have finally confirmed the contract to the German Gutehoffnungshütte for the construction of an iron and steel plant near Pukow, China. Instead of 500,000 tons, as originally planned, the plant will produce only 250,000 tons annually—as the coal near Pukow is unsuitable for iron production and must be supplied by the far-distant Kao Kang mines of the An Yua district in Kiangsi. The total cost of the plant will be £4,000,000, and it is expected to start production in 1937.

A company known as Metallics and Non-Metallics, Ltd., is now undertaking the development of a natural sodium sulphate deposit some 40 miles north of Maple Creek, Saskatchewan, estimated to contain more than 25,000,000 tons of Glauber's salt—the largest deposit of its kind in the British Empire. The sulphate as it occurs in the lake is in crystal form, and contains 59 per cent. water of crystallisation, which must be driven off in connection with the conversion of the sulphate into salt cake. Plant construction will entail the expenditure of 150,000 dollars.

In an article in *The Edgar Allen News* on dredger tumblers, the author says: "It will be obvious from what has here been written, that the steel founder can perform a valuable service in devoting his energies to the solution of practical difficulties experienced by his customers. There is always something to be gained and nothing to be lost by communicating to the steel founder the practical troubles experienced in connection with the use of steel castings in particular operations, and more often than not collaboration between user and founder can result, as in the instance of manganese tumblers, in an improved product that successfully meets requirements."

It is claimed, says the *Morning Post*, that there is enough oil shale below the ground at the village of Sutton Poyntz, near Weymouth, to supply the whole of England indefinitely with petrol and oil. This claim is made by an Italian engineer, Dr. M. Marconi, who states that he has discovered a secret process whereby oil can be extracted cheaply from the vast deposits of shale on the Dorset coast. A company has been formed by Dr. Marconi, Mr. Herbert Weld, of Lulworth Castle, influential Dorset landowners, and Mr. T. B. Bertuccioli. At present a small factory is being erected at Sutton Poyntz on land belonging to Mr. Hugh Diment. The promoters state that they expect to find employment for 100 local men within the next five months.

TWO STANDARDS.

The evidence that this country is gradually rising from its industrial depression increases daily in strength and volume. The fear that rising hopes may be doomed once more to disappointment is slowly being replaced by a feeling of confidence. Inquiries are more frequent and firmer, and order books are beginning to fill up; employment is increasing rapidly and the prospect for the immediate future is good. All that now may be dreaded is some political action, either at home or abroad, which will check the acceleration. Provided that we are spared that infliction the revival rests with the producers and distributors themselves. The home markets are fairly secure, but we cannot live on our inland trade. Our manufacturers and our salesmen must look overseas, for it is there that we must seek for business to restore our trade to its normal dimensions, and it is just there that we have the greatest anxieties to face. There is no question of the severity of the competition. It is so severe that some people have spoken of it as unfair. Japan's competition has been so described, though it is difficult to see any unfairness in that kingdom producing cheaply if its economic system allows it. We cannot produce as cheaply as she can, because we have decided to insist upon a higher standard of living; it is absurd to charge her with unfairness because she retains a standard of living which suits her, but which we think too low. Indeed, complaints and recriminations are fruitless; what we have to do is to make our markets in the face of the competition of other countries, and the only unfairness of which we have any right to complain is that imposed by our own legislation or regulation, or customs of trade, or taxation, or rating, or cost of transport, and so on. Such things may be fetters about our ankles and may impose conditions which make revival difficult or doubtful. But it is our own business to set them right.

Amongst such factors we have to place for consideration, not for hurried condemnation, the standards set up by the B.S.I., and other standardising bodies. There is little doubt that in certain markets the price which accompanies the British standard of quality is too high. The foreigner with lower standards and lower prices secures the orders. We have already referred at some length to this important question—on June 3rd, 1932, and on September 29th last, when we printed a long letter which the British Standards Institution had sent to the British Chamber of Commerce in Buenos Aires in reply to a complaint made by the Chamber of the high price and unnecessary excellence of British goods. We return to the subject again, because of its great importance, and because further light has recently been thrown on one of its aspects. It will be recalled by those who followed the Buenos Aires correspondence that the possibility of adopting two standards was adumbrated. Let it be admitted that many purchasers are wise enough to pay the extra price for goods of quality, and even that more could be induced to do so by better salesmanship. There still remain many who are quite content with the lower standard offered by foreign producers; who do not ask for the safety of British machinery, and regard its long life as a hindrance to progress. They are quite prepared to subject life and limb to reasonable risk and do not mind overstressing machinery and structures so that they wear out rapidly. There is no question that this kind of market exists, and none, that we cannot touch it—because our prices are too high. We are faced then with two alternatives to the loss of the trade; either the production of a lower standard to suit these markets, or the retention of the present standards, but at a price equal to or below that of our competitors. The latter is almost unthinkable for such goods as we have in mind. In these days there are no national secrets about methods of manufacture; what one nation can do another may. The price for the same thing cannot be appreciably reduced below that of other nations by a new method of production. It can only be lowered by offering something different or by reducing the standard of living. It is true that the prices of many engineering products are maintained by price rings and associations, but it is very doubtful that they are excessive for the quality given. Hence, one of our two alternatives is removed, and we are left with the possibility, or, let us say, the desirability, of setting up two standards, one of quality A, and the other of quality B. The arguments for and against doing that have not yet been fully explored, but there is, undoubtedly, a feeling that it would be a retrograde step, and that sooner or later the lower standard would drive the higher from the field. The obvious answer to that contention is that if the lower standard satisfied the market, there is no reason why the higher should be retained. Another argument against two standards is that confusion would certainly occur, and that the British reputation would suffer just as certainly if the lower standard failed. Others contend that even a lower standard would not capture the market against local producers and cheaper competitors, and there appears to be a general consensus of opinion that more harm than good would be done by anything which prejudiced the reputation for excellence which this country enjoys.

In a sense, it may be said that our British Standards are defeating themselves. Before they existed all manners and qualities of products were made, and the British manufacturer could compete hopefully in any market in the world because he modified the quality to suit the price obtainable. But since the coming of British standardisation, the advantages of following standard specifications on the home and Empire markets are so great that alternative designs and qualities are, to a large extent, disappearing. Furthermore, the foreign purchaser insists on using the British specifications when he orders goods in Great Britain, but will accept the specifications of other countries if he is ordering in them. Until we get international standardisation that will be a constant difficulty. Of course, there are always plenty of manufacturers in this or any country who are prepared to supply goods not made to the national standards, and it might be thought that these people would supply the lower class of goods required by cheap markets. Fortunately, or unfortunately, that is only partly true. The general and increasing tendency, as we have said, is to specify British standards, and that immediately settles the quality, and, to a very large extent, the price. The position is, then, that we are not prepared to give up our high standard, that two standards will not be considered, and that our prices cannot be appreciably reduced. Success, in these circumstances, must depend upon the ability of the salesman to convince the purchaser that the extra cost is worth while. We are proud to be able to record the evidence of overseas observers that it is the first order which counts; after that, the excellence of the British products favours the salesman.

Street Design.

Nearly everyone with experience of modern traffic conditions in large towns must, we imagine, have amused himself in times of leisure by attempting to plan some ideal lay-out of streets in urban areas by which all troubles of traffic congestion would be overcome and all the demands of road users met in full. The subject, indeed, is so fascinating that nearly every writer upon it has allowed his imagination to run riot, so that, in effect, anything of value he may have had to suggest was concealed beneath a load of quite impracticable visions. Doubtless, the provision of "throughways," raised upon viaducts over our present streets, and limited for use to the higher speed vehicles, together with access ramps and all the other typical, but impossibly expensive, paraphernalia of the usually suggested scheme, would cure urban areas of acute congestion. But, short of taking the whole War Debt due from this country to America and diverting it to a directly utilitarian purpose, the likelihood of any such scheme ever being carried out on the large scale it demands is remote. An entirely sane paper which takes street lay-out as it is to-day and modifies it in accordance with modern demands is, therefore, a welcome addition to the literature on the subject. Last Monday, Mr. H. Allen Tripp read such a paper before the Institute of Transport. He is an Assistant-Commissioner of the Metropolitan Police, and is, therefore, in a position to view the question of transport, not, perhaps, from an independent, but certainly from an unbiassed standpoint. Certainly, in his review of the subject and the suggestions that he makes, he keeps a tight rein upon his imagination, so that the improvements he advocates involve no heavier expenditure of public funds than could easily be borne. The suggestions, in fact, are so sane, and arise so surely from an analysis of the requirements of both the road itself and its users, that one labels the paper "common-sense" at once.

Mr. Tripp adopts an attitude half-way between that which calls for a road that meets the needs of the traffic upon it and that which considers that the traffic should be regulated to suit the roads. His discussion, for instance, of the rights of various road users comes under the latter head. In his own words—"At present, inheriting the habits of a leisurely past, the wealthy shopper generally expects his or her vehicle to wait outside the shop while purchases are made. This, in the crowded thoroughfares of inner London, has ceased or is ceasing to be practicable, and in view of traffic necessities the demand cannot be conceded as a just requirement. Nearby standing accommodation (off the road) . . . will have to be the solution . . ." Or, again, "The demands made by tramcars are heavy. They demand a track upon which they shall have priority over other traffic, and also expect that when they stop for passengers . . . all other traffic going the same way shall stop also . . . the demands are far too high to be conceded to one specialised form of transport." Similarly, he believes that the claims of frontagers cannot be met in full. "The demand that highway accommodation should be provided in order to further private gain, at the expense not only of the public purse, but also of the convenience and even safety of public traffic, is thus another demand that cannot equitably be conceded." Premises which attract local traffic, in fact, must provide at their own expense standing space off the highway for the vehicles. Such points, and many others, which Mr. Tripp brings forward are concerned with the fitting of the traffic to suit the roads. On the other side—making the roads to fit the traffic—he has so much to say that it would be difficult to do justice to it by means of extracts. Arising from a careful analysis of the requirements in a good road and the equitable claims of road users, he divides streets into two classes—the arterial and the distributive. The latter exhibits little alteration from those we know to-day. But in the former everything is subordinated to the main object of keeping the traffic flowing freely. The highway ends of side roads are closed and built upon. At crossings, of which there are not more than three to a mile, there are roundabouts or traffic signals. The road is wide and divided centrally by an island, which is interrupted at long intervals to suit cross roads and accommodate taxi-ranks. Standing of cars on the road surface is prohibited. Pedestrians are only permitted to cross at certain clearly defined points, and under the protection of light signals. That there shall be no possibility of their attempting to do so elsewhere, the pavement is railed off from the road, and the railing is only interrupted at omnibus stops, near the heads of taxi ranks, and at pedestrian crossing places. Great arterial roads radiating from the city would be designed on a similar plan. "We would have our road fenced on both sides from end to end. No houses whatever fronting it should be built. Roundabouts of adequate dimensions having been provided at each of the intersections, these would be the only entries permitted. At each junction a footbridge, approached by easy ramps, would be provided. No pedestrians would under any circumstances be allowed to set foot on the carriageway save in case of emergency . . . It may be objected that an arterial road of this character with so few approaches would be in the nature of a fence as between the adjoining portions of the country. The answer is that it would be less of a dividing line than any new railway track."

The greatest resistance to any such scheme as that advocated by Mr. Tripp is likely to be exerted by the pedestrian. The motorist, we think, might be not unwilling to waive any right he has to leave his car before the premises he wishes to visit in consideration of the increased speed and safety of travel upon the new arterial road. But the pedestrian—and the motorist is almost as much a pedestrian as anyone else—still clings in this country to his ancient right to use the roadway at any place and time to suit his own convenience. To quote Lord Buckmaster, "pedestrians are on the road by right, and the whole of the motor traffic is there by licence, and people there by licence have no right to interfere with the rights of people who were there before motor cars were thought of." In other countries, however, the pedestrian has already had to submit to a limitation of his rights, and in certain cities of the United States he is even subjected to a fine if he attempts to cross the road elsewhere than at certain clearly defined points. In the words of Mr. Tripp: "It is just as if there were a right of way from time immemorial over land upon which the sea has now suddenly encroached. People may still assert their right to the footway, but if great waves are apt to be washing right across it is not always policy to exercise the right." If we may add one more argument to the many that Mr. Tripp brings forward, the restraint exercised upon the pedestrian by the railing of the road, and the restraint exerted on the motorist by the central island, might between them do much to bring about a much-desired reduction in the appalling death-roll of the road.

The Sulzer Single-Tube Steam Generator.*

By Professor A. STODOLA, Zurich.

No. I.

THE Sulzer single-tube steam generator—illustrated and described in THE ENGINEER of October 14th, 1932, consists of a continuous tube, constructed by welding, in which the feed water is preheated and evaporated, and the resulting steam superheated. The increase in volume of the water and steam raises the velocity of flow in such a way that it is quite impossible for steam bubbles to remain on the sides of the tube, and heat transmission is considerably improved. Careful regulating tests on one of the first of these steam generators to be constructed prove that the superheat temperature is strictly under control and that the working medium passes from one state into the next without any trouble, even when the load on the boiler fluctuates greatly and suddenly.

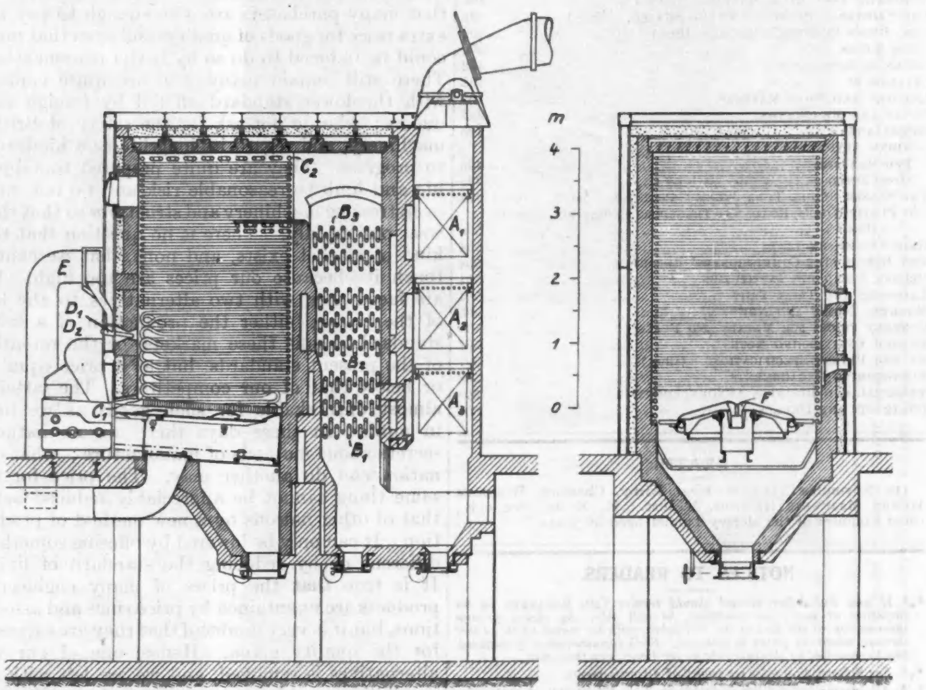

FIG. 1—SULZER SINGLE-TUBE BOILER IN A DYE WORKS

Pressure, 100 *atm.; Steam Temperature,* 400 *deg. Cent.; Output,* 7·5 *Tons of Steam per Hour.*

F—Coal passage in underfeed stoker; left and right of the grate, clinker removers.

Naturally, the counterflow principle is adopted, *i.e.*, the feed water is introduced where the flue gases leave the generator, and evaporation and superheating take place where the tube is subject to radiation from the burning fuel.

THE FIRST SINGLE-TUBE GENERATOR.

The first commercial Sulzer single-tube steam generator was installed in the dyeing and bleaching works of Charles Weber, Ltd., Winterthur, and was started up in 1932. This steam generator, illustrated in Fig. 1, has a heating surface of 195 m.², of which 74 m.² are in the combustion space; the tube is 1300 m. long. Steam is raised at 100 atm. gauge pressure and 400 deg. Cent. temperature and drives a De Laval turbine of 500 kW output, and also supplies the works with heating steam, for which purpose the steam is condensed at a pressure of 9–10 atm. abs. in a high-pressure condenser (a "steam transformer") and then led back to the steam generator. The heat of condensation evaporates the "cooling water," which is at a pressure of 8 atm. abs., and is preheated in a flue of the steam generator. Fig. 2 shows the front of the steam generator.

In larger units—as, for example, in the steam generator, raising 18 tons of steam per hour, supplied for the district heating station of the Technical University of Zürich—the arrangement of the tube is as shown in Fig. 3.

The type of welding adopted by Sulzer Brothers consists, as shown in Fig. 4, in expanding the ends of the tubes and inserting in them a nipple provided with a cone at each end; the nipple ensures correct alignment and prevents drops of the weld metal penetrating into the interior of the tube. The slight reduction in bore caused by the nipple induces an eddying in the neighbourhood of the welded joints which has a favourable effect on the heat transmission; the loss in pressure is practically negligible.

THE REGULATION OF THE GENERATOR.

The following considerations show that the regulation of the single-tube steam generator, *i.e.*, adjusting the rate of steam raising to suit the momentary requirements of the service, and particularly to ensure that the final temperature of superheat always remains unchanged, may be no easy task.

With a tube 1300 m. long a particle of water requires 8⅜ minutes from the time it enters the tube until it issues at the other end in the form of steam. If the rate of steam raising is halved the time required for the particle to traverse the tube is increased to 17 minutes. Hence a considerable lag before a change in the rate of feed produced an effect might be anticipated. Fortunately, that is

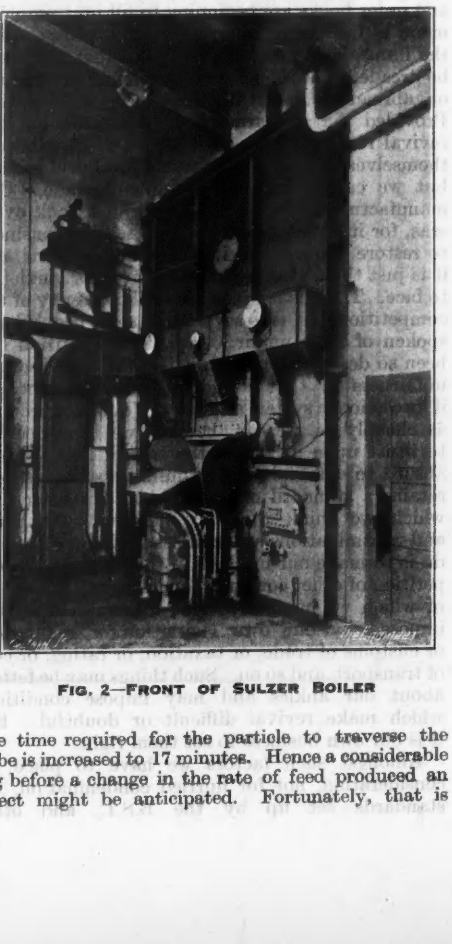

FIG. 2—FRONT OF SULZER BOILER

---

* Translated and abridged.

not the case. A sudden increase in the feed pump pressure, for example, is transmitted almost instantaneously to the spot where evaporation begins, since the " wave " passes through the " solid " water column filling the preheating zone with the "velocity of sound," about 1000 m./sec., and the velocity of flow is consequently correspondingly increased. Hence more water at once begins to evaporate, and the steam requires, in the case under consideration, only 37 seconds to reach the end of the tube, when the boiler is working fully loaded. Finally the quantity forced into the tube by auxiliary injection at the spot where superheating begins requires only 13 seconds to traverse the rest of the tube with the boiler working at full load. But even this time lag, compared with the instantaneous restoration of balance by the turbine governor, is quite considerable. Hence means had to be devised to effect closer regulation.

Steam Supply Regulation.

The solution adopted for the regulation in the first generator was suggested to a large extent by the following fundamental considerations :—

(1) A change in the rate of steam raising has to be effected in such a way as to maintain the temperature at the outlet as constant as possible. Just as in a centrifugal governor, the drawback which has to be prevented must be allowed to occur to a certain extent, *i.e.*, the regulating devices can only be made to function when the final steam temperature exceeds or falls below the normal temperature by a certain amount. If then, for example, the upper limit of temperature is reached, a certain balance between the heat introduced and the momentary rate of steam raising may be obtained, and a further increase of the amount of feed water delivered would then mean " over-regulation." Delivery of feed water is consequently of the greatest importance during that regulating period, when there is an excess of heat introduced above what is required for the momentary steady rate of steam raising. Consequently, it is not only the excess temperature which is used to determine when regulation shall be effected, but also the differential quotient of that excess with regard to the time $= d\,T/d\,z$. For this reason the corresponding part of the regulating device is called a " differential regulator."

(2) It is, of course, self-evident that when the load on the boiler increases, the intensity of the firing must be increased as well as the quantity of feed water delivered. But the rate of steam raising, the intensity of firing, and the quantity of feed water are all functions of each other of a particular kind, and the regulating devices have to take account of this.

The type of construction adopted for the whole regulating arrangement is based on the general adoption of hydraulic control and hydraulic remote transmission, the reliability of which has long been recognised by the makers of steam turbines.

The principal organs of the regulating apparatus are the following :—

1. *Remote Temperature Indicator.*—The difference in expansion between a straight tube, 2600 mm. long, projecting outwards, and an equally long rod of Invar steel (with a coefficient of expansion of about 10^{-6}), which is subjected to the temperature of the boiler-room, is transmitted, as shown in Fig. 6, to a control apparatus, in the upper part of which a "pulsating" movement is produced. The face *g* of the valve B connected with A is under the influence of pressure fluctuations between 0 and 10 atm., so that the valve, by means of the back-pressure face *f*, is caused to pulsate up and down ±0·3 mm. The valve A also follows the motion of the end of rod F and operates by means of levers G and L the control valve N, and by means of N the piston S fitted with usual compensating motion. Spring V presses valve U downwards, so that pressure oil forces its way through openings W into the space T until balance with the spring pressure is restored. R is the oil outlet, D the pulsator oil, 0 to 10 atm., P the pressure oil inlet, and E the regulating oil. The increase of pressure in the space T, as compared with the initial state, is therefore proportional to the distance passed through by the end of the rod F, *i.e.*, proportional to the increase in temperature above the normal. The "regulating oil," thus produced, is the working medium for the actual regulating members. The whole device is termed a " thermostat " by the makers.

2. *Differential Regulator with " Summation Valve " for Directly Influencing the Temperature*.— As mentioned above, the differential regulator has to control the quantity of feed water delivered in accordance with the rate at which the temperature rises, independently of the absolute height of the temperature, *i.e.*, approximately in proportion to $d\,T/d\,z$. This is effected by causing a piston to move up and down in accordance with the temperature, thus expelling or drawing in the contents of the cylinder through a throttle opening. The resulting oil pressure is very nearly proportional to the speed of the piston, and consequently also to $d\,T/d\,z$. How this result is realised in practice is shown in Fig. 7. Here the (temperature) regulating oil enters at A below the spring-loaded control valve B, which, when raised, allows pressure oil to pass by way of the tube *a* and then under the servo-motor piston C, which raises the piston D and brings the valve B back to its middle position by means of the compensating lever F. During this movement the pressure under D falls (even below atmospheric) in consequence of the throttling of the oil by the opening E. This fall in pressure is transmitted to the valve G, so that it—by the spring H—lowers the valve J and allows pressure oil to flow past the edge K into the space L until the oil pressure rise in L has compensated the fall in pressure on G and brought the valve J back into the middle position. R is the oil outlet, S the pressure oil inlet, P the regulating oil from thermostat, and T the regulating oil to control valve of feed water regulator.

The influence of the absolute height of the temperature is at the same time made effective in a very ingenious manner, the same regulating oil as at A being led also to the piston M in the space N, so that with the help of the springs H and H_1 the control valve J may be at the same time influenced independently, and can cause a corresponding rise in pressure in L. The pressure in L is consequently at all times the sum of the temperature regulating pressure and the (algebraic) value of the pressure changes caused by $d\,T/d\,z$ in the space below D. The part composed of M H G J is therefore rightly named " summation valve."

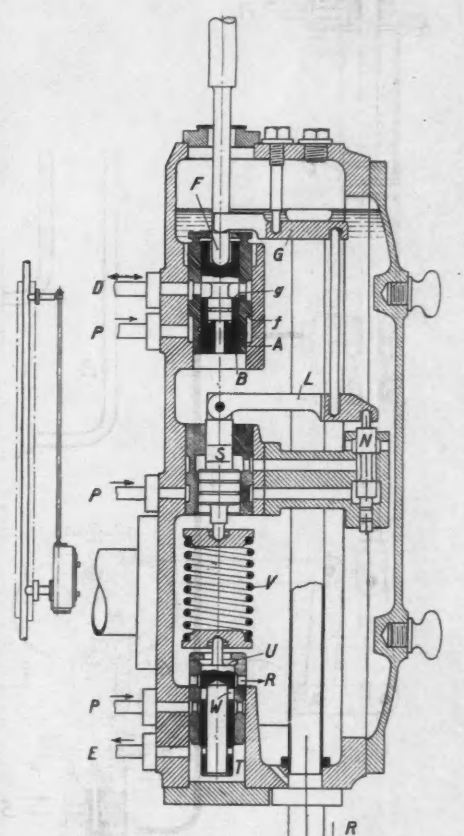

Fig. 6—Remote Temperature Indicator

3. *Injection Regulator with Positive Compensating Motion* is shown in Fig. 8. The regulating needle A, which is in the form of a sharply tapered cone and allows the feed water to pass through the pipe B to the injection point, is raised and lowered by the long-stroke servo-motor piston C, which is controlled in the usual manner by the valve D. The piston is lowered by the needle pressure and an additional weight, so that pressure oil is necessary only for raising the piston. On the lower face of the control valve D, the regulating oil of the temperature indicator acts at E. The total pressure acting on the lower face of the valve (neglecting the weight of

FIG. 10—PRESSURE REGULATION

A—Steam pipe from boiler.

1 —Connecting pipe for steam pressure.
2 —Plunger.
3 —Valve.
3'—Vessel filled with cylinder oil.
4 —Rod.
4'—Oil make-up.
5 —Spring.
6 —Hand wheel.

B—steam pressure receiver.

7 —Regulating oil space.
8 —Pressure oil pipe.
9 —Outlet.
10'—Pulsator oil pipe.
11 —Regulating oil from thermostat.
12 —Control valve for turbine valve.
13 —Safety valve
14 —Annular space.

C—Turbine valve.

15 —Cock.
16 —Space under servo-motor piston.
17 —Servo-motor for turbine valve.
18 —Steam pressure regulating valve.
19 —Control valve for by-pass valve.
20 —By-pass valve.
21 —Starting valve.
22 —Annular space.

D—By-pass valve.

23 —Cock.
24 —Space under servo-motor piston.
25 —Servo-motor.
26 —Hand-operated valve.
27 —Connecting oil pipe.
28 —Pressure oil inlet.
29 —Pressure oil inlet.

the valve itself, which is slight) is taken by the spring F, which is held against the cam H by means of guide piston G and roller G^1. When the servo-motor piston C falls, the valve is brought back into the middle position by means of the cam H, the pressure of the spring being increased. R F is the oil outlet, S the pressure oil inlet, and T the cooling water inlet.

4. *Feed-water Regulator with Isothermal Compensating Motion* is shown in Fig. 9. A slightly tapered regulating needle A allows the excess feed water to pass through B into the suction piping, when the feed pump, as in the present plant, is set to deliver a fixed total quantity. The serve-motor piston C is controlled by the valve D, the combined pressure coming from the differential regulator acting on its under face at E. With an increase in the feed-water delivery, the return motion is effected through the oil forced by the servo-motor piston C upwards out of H towards H_1. This oil presses the valve D back into the middle position by means of piston K_1 and spring F_1. Spring F and the spring F_1 loaded by the piston K_1 serve to compensate the regulating oil pressure in E. For isothermal action the throttle opening L is essential. It allows the spring F_1 to expand, thus causing a renewed raising of D and C, and also an increase in feed-water delivery, *i.e.*, a temporary over-regulation. In consequence of the fall in temperature which now takes place, the pressure at E will fall and the temperature, after some fluctuations, will return to its initial value when the oil brake is properly adjusted. The spaces round F and F_1 are connected to the collecting vessel M for the removing of any oil which oozes out. N, P = cocks for adjusting the feed-water regulator by hand; R = oil outlet; S = pressure oil inlet; T = cooling water inlet.

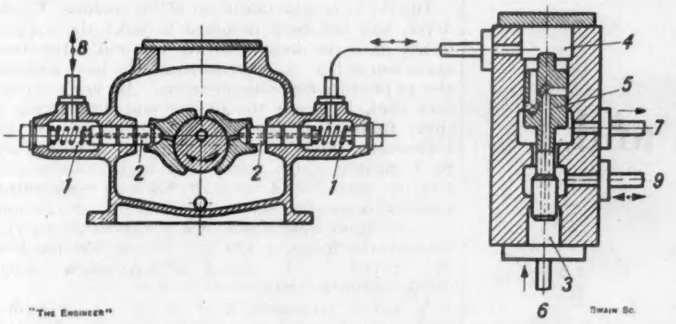

FIG. 11—PULSATOR

1, 4—Pulsating oil column.
2—Plunger.
3—Pressure-oil space.
5—Vibrating valve.
6—Pressure-oil connection.
7—Oil outlet.
8—Pulsator oil pipe for steam-pressure controller.
9—Pulsator oil for thermostat (0 to 10 atm.)

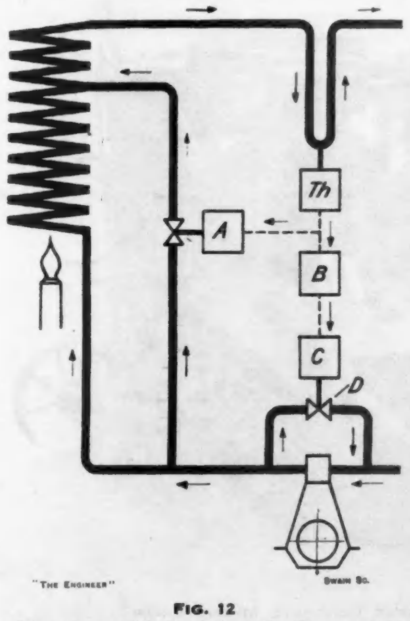

FIG. 12

General Arrangement of the Regulation with a Thermostat at Steam Outlet.

A—Injection regulator with positiye compensating motion.
B—Differential regulator.
C—Feed-water regulator (isothermal).
D—By-pass valve for feed water.
Th—Thermostat.

5. *Injection Regulator with Isothermal Compensating Motion.*—This regulating device, which was used during the tests described below, may also be considered as described by Fig. 9, when one imagines the injection to be below A and the inlet and outlet for the pressure oil on the valve casing to be interchanged in the manner shown in Fig. 8, the influence of the compensating motion being also altered appropriately.

6. *Appliance for Hand Control of the Regulation.*—Simple cocks allow the servo-motor to be connected alternately with the pressure oil piping and the oil outlet. Thus, for example, the cock marked N in Fig. 9, when turned through 45 deg. in a counter-clockwise direction, serves to connect the upper side of the servo-motor piston with the pressure oil. The oil forces the control valve downwards, and this, in turn, causes the servo-motor piston to fall, in consequence of its underside being connected to the outlet. The quantity of feed water delivered to the boiler is consequently reduced. The contrary takes place when the cock is turned through 45 deg. in the clockwise direction.

If the cock marked P in Fig. 9 is turned through 90 deg. in a counter-clockwise direction, the servo-motor piston passes quickly into its highest position, and the quantity of feed water delivered to the boiler is thus set at its maximum value. The cock may also be turned into the same position when the generator is being stopped, if it is considered necessary to cool the tubes and the boiler setting quickly.

The injection regulation with isothermal return motion may also be operated by hand in a similar manner.

7. *Pressure-regulating Device.*—In the plant tested at the works of Charles Weber, Ltd., Winterthur, the pressure in the generator is regulated to remain constant, and it was necessary, in addition to the "turbine valve" controlling a turbine, to fit a "by-pass valve," which leads the steam direct to the high-pressure condenser. Because of the method described below for starting and stopping the generator, it is not possible to dispense with this by-pass valve even in ordinary power plants.

The essential parts of the pressure regulation (Fig. 10) are: The pressure receiver, the steam pressure regulating valve 18, and the by-pass valve 20. The method in which they work is as follows:

The steam pressure on the piston face of the plunger 2 is transmitted to the valve 3, and through the rod 4 to the spring 5. Its height is adjusted by changing the spring tension by means of hand wheel 6. In space 7, and in regulating oil pipe 10, an oil pressure proportional to the steam pressure is produced.

The safety valve 13, during normal service, remains in its top position, so that the middle space 14 of control valve 12 is connected with the space 16 of the servomotor 17 through cock 15, which, in the figure, is shown in its working position. With increasing oil pressure in the system 10, *i.e.*, with increasing steam pressure, the steam pressure regulating valve 18 leading to the turbine is opened, and with falling oil pressure closed. The starting valve 21 is, in normal service, kept in its top position by pressure oil from pipe 28, so that space 22 of the control valve 19 is connected with space 24 of the servo-motor 25 through cock 23. When starting, valve 26 connects pipe 27 with system 10. Therefore, if the steam pressure is still insufficient, valve 21 is in its lowest position, so that the pressure oil entering through pipe 29 opens the by-pass valve 20 completely.

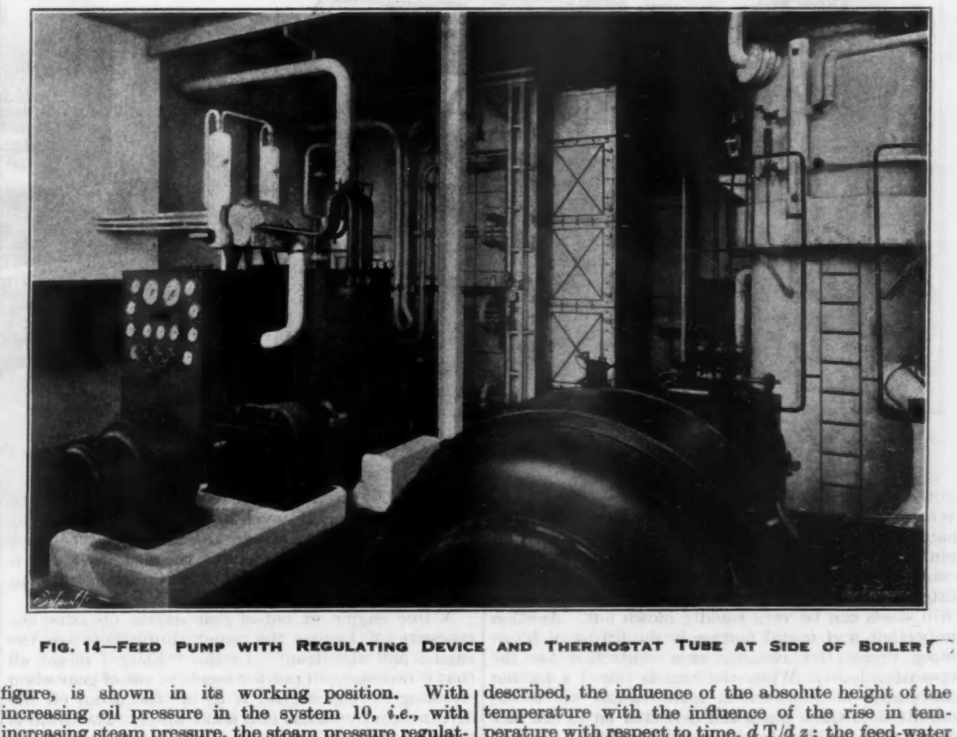

FIG. 14—FEED PUMP WITH REGULATING DEVICE AND THERMOSTAT TUBE AT SIDE OF BOILER

Valve 13 is intended to protect the turbine from too low temperatures, *i.e.*, from water hammer. For this purpose the regulating oil from the thermostat acts on the lower face of the piston. If the temperature sinks below about 350 deg. Cent., the valve falls and connects the servomotor piston space 16 with the outlet, whereby the turbine valve 18 is closed.

8. *Pulsator, i.e.*, the necessary device for maintaining a continuous slight fluctuation in pressure in all parts of the regulating device is shown in Fig. 11. The oscillations of all movable parts constantly caused in this manner, makes them respond more quickly to the slightest change in the mean pressure, and almost entirely eliminates the risk of any member seizing.

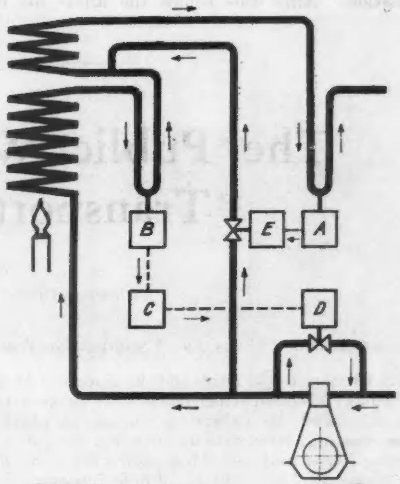

FIG. 13

General Arrangement of the Regulation with a Thermostat at Steam Outlet and an intermediate Thermostat before the Injection Point.

A—Thermostat at end of tube.
B—Intermediate thermostat.
C—Differential regulator.
D—Feed-water regulator (isothermal).
E—Injection regulator (isothermal).

COMPLETE ARRANGEMENT OF THE REGULATING DEVICE WITH A THERMOSTAT AT THE STEAM OUTLET.

The regulating parts just described may be grouped together in various different ways. The arrangement shown in Fig. 12 is that which is chosen for ordinary power plants with many prime movers and steam generators, where the load variations do not as a rule exceed more than 20–30 per cent. of the maximum output of one unit.

Here the end thermostat Th acts directly on the injection regulator A, which works with mechanical compensating motion, and also on the differential regulator B. In the latter are combined, as already described, the influence of the absolute height of the temperature with the influence of the rise in temperature with respect to time, dT/dz; the feed-water regulator C, which is set for a constant temperature, is thus operated. D is the by-pass valve for the feed water.

COMPLETE ARRANGEMENT OF THE REGULATING DEVICE WITH A THERMOSTAT AT THE STEAM OUTLET AND AN INTERMEDIATE THERMOSTAT BEFORE THE INJECTION POINT.

Fig. 13 shows the arrangement intended for regulating plants in which importance is laid on the closest regulation, even with great and sudden fluctuations in load. As can be seen, in addition to the end thermostat A, an intermediate thermostat B is arranged directly before the injection point. From the intermediate thermostat the regulating oil controls the differential regulator C, which is connected with the summation valve controlling the feed-water regulator D. The feed-water regulator is under the combined influence of the absolute height of the intermediate temperature T and its variation according to time, dT/dz. The regulating parts B C D, since they are subject to the great time lag in the long tube, constitute a kind of pre- (or coarse) regulation. After this comes the after- (or fine) regulation by means of the injection regulator E, which acts in this case with isothermal compensating motion. Since the steam flowing towards the injection regulator has already been treated, the regulator must act more promptly and therefore a very complete balance of temperature may be expected in a very short time.

As shown in Fig. 14, these regulating parts can be brought together into a box which takes up very little room (as can be seen from the measuring apparatus). The looped tube of one of the thermostats can be seen in the background.

(To be continued.)

The Public Works, Roads, and Transport Exhibition.

No. II.

(Continued from page 456, November 10th.)

The Climax Rock Drill and Engineering Works.

The Climax Rock Drill and Engineering Works, Ltd., of 4, Broad-street-place, with works at Carn Brea, Cornwall, are exhibiting pneumatic plant for stone dressing, rock drilling, digging, &c., and for dressing kerbs and setts, together with some drill-sharpening machines and an oil-fired furnace.

We illustrate one of the smaller sizes of drill sharpeners in Fig. 21. This machine has been designed to meet the needs of the smaller mine, quarry, or contractor, where jack-hammer drills are used and bits not exceeding 2⅝in. in diameter are required. The swaging ram is operated by an air cylinder in the base, and is pulled down by side rods. The ram also acts as a gripping vice. The dollying hammer is mounted on the same base, at right angles to the swaging ram, and faces the operator. In addition, to the right of the dollying hammer, there is a knock-in and knock-out pin punch, for opening out the hole in the shank or bit on hollow drill steel. The punch is fed forward by an air feed and at the same time it is hammered into the hole of the steel. When the desired depth has been reached, it is hammered out by reversing the control lever. A pin puller is fitted at the side of the machine, and is controlled by a foot lever. A blow-out device is fitted to the front of the machine by means of which drill steels can be very rapidly blown out. Another important and useful feature is the fitting of blowpipes under the swaging ram controlled by the operating lever. When the ram is raised a further movement of the control lever causes air to be admitted to these pipes and deflected on to the face of the dies, rapidly clearing away the scale.

The operation of the machine is controlled by a single lever. A slight movement of this lever closes the swaging ram on the steel stock. A further movement brings the dolly hammer into operation, and on release of the lever the dolly hammer ceases operation. When used for swaging, the ram gives any number of sharp, quick, but powerful blows, by means of short movements of the operating handle. The dolly is retained in the dolly cylinder by means of a plunger acted upon by air pressure, thus obviating the use of springs, which are a constant source of trouble. The weight of the machine is about half a ton, and it requires 55 cubic feet of free air at a pressure of 80 lb. per square inch.

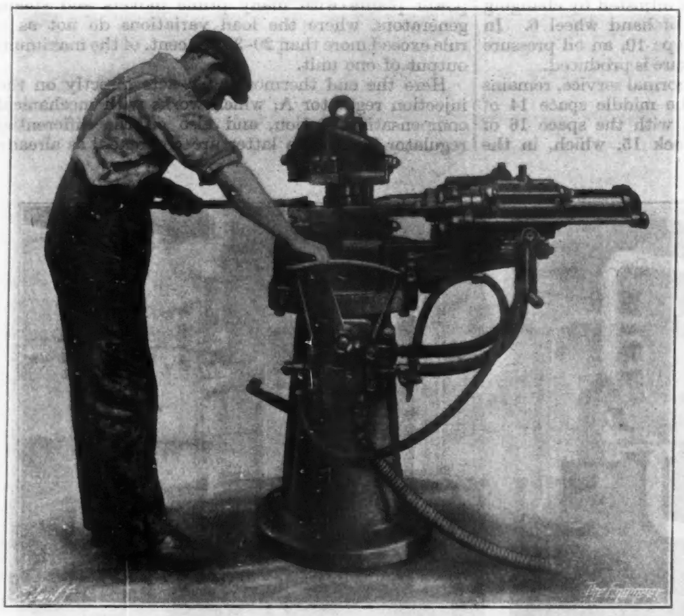

Fig. 21—Rock Drill Sharpener—Climax

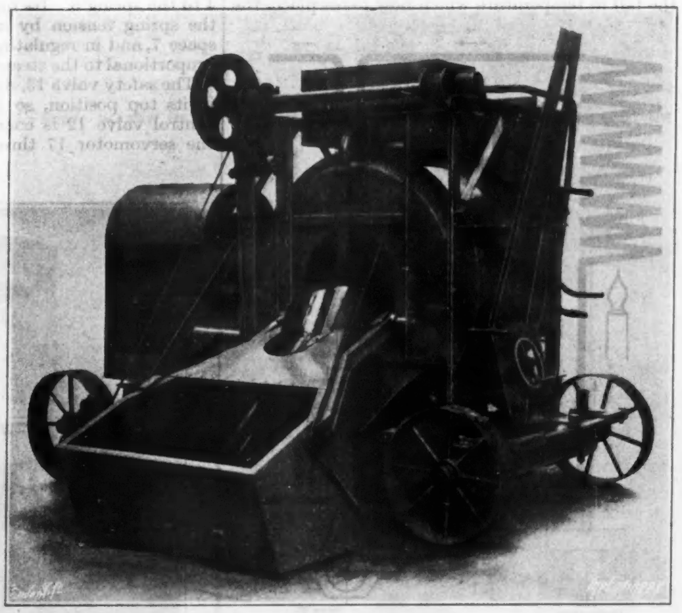

Fig. 22—Portable Concrete Mixer—Liner

The Liner Concrete Machinery Company.

For the first time the Liner Concrete Machinery Company, of Glasshouse Bridge, City-road, Newcastle-on-Tyne, is showing a concrete mixer of the rotary drum type. It is illustrated by Fig. 22. There are, however, mixers of other types on this stand.

The rotary drum mixer has a capacity of 10/7 cubic feet, and is, it will be seen, of the portable type. It is driven by an enclosed petrol engine. One of the outstanding features of the machine is the arrangement for carrying the drum, which is mounted on four rubber-tired rollers, two of which are driven by the engine through machine-cut gear wheels. This method of mounting and of driving the drum has the advantage that it dispenses entirely with the customary gear ring or chain wheel round the drum, thus enabling the drum to be readily removed from the machine. A smooth, even and silent rotation of the drum is obtained with no metal-to-metal contact, and with no external wear of the drum. There is also less noise, which means less vibration and consequently less wear.

A free engine or out-of-gear device obviates the necessity of having the usual clutch between the engine and the drum. In the "Liner" mixer all that is necessary to put the machine out of gear when cranking up the engine, is to lift the drum off the driven tires by means of a hand wheel. The drum is then lowered on to the revolving tires and immediately starts to revolve.

The direction in which the control lever of the hopper-raising gear is moved for the in-gear or hoisting position is directly opposite to that for the lowering position, instead of the lowering position being, as usual, half-way between the hoisting and the braking position. The effect of this is to dispense almost entirely with the gap or period when the hopper is out of control when changing from hoisting to lowering, and *vice versâ*. Safe and smooth working results without necessity for fine adjustment, and wear and tear is reduced.

Millars' Machinery Company, Ltd.

The most novel exhibit on the stand of Millars' Machinery Company, Ltd., Pinners' Hall, London, E.C.2, is the plant, illustrated by Fig. 23, for making tarmacadam, bituminous macadam, and asphaltic road surfacing mixtures. It has the outstanding feature that it can be worked at widely different temperatures, and consequently will do the work for which two plants are usually necessary. It has a capacity of 10 tons per hour.

The dryer is a modification of the makers' T.B.M. dryer, and has been designed to meet the requirements of users manufacturing tar and bituminous macadam at low temperatures and who have occasion also to produce asphaltic mixtures. By low temperature work is meant the drying and discharging of stone from 2½in. down at a temperature varying between the limits of 90 deg. Fah. and 120 deg. Fah., the capacities stated being based on a moisture content not exceeding 4 per cent. By high temperature work is meant the drying, heating, and discharging of stone from 2½in. down at a temperature varying between the limits of 400 deg. Fah. to 450 deg. Fah. The output stated is based on a moisture content not exceeding 6 per cent.

A special arrangement of lifting and propelling blades fitted inside the drying drum ensures that graded material can be passed through and discharged with very little variation from the initial grading, this variation usually not exceeding 1½ per cent. The design allows the fine material, *i.e.*, ⅛in. and down, to be retained in the drum and discharged with the larger stone. Alternatively, all dust can be extracted by means of special doors fitted at each end of the dryer, and collected, if need be, in a cyclone type dust collector.

On the low temperature work the dryer operates on the "parallel-flow" system, the drying being effected by means of large volumes of warm air drawn down the drum by a large fan. The air enters the dryer through adjustable inlet ports and intermingles with the hot fuel gases as it passes down the drum. The inlet ports are adjustable so that any quantity of air can be introduced to the dryer in addition to that delivered through the secondary air ports arranged for the combustion of the oil fuel. With this arrangement a great variation in the adjustment of the burner is possible, enabling the burner to operate from a quarter open to full open to suit the moisture content and the terminal temperature required. Strict uniformity of temperature is a noteworthy feature of this arrangement.

On high temperature work the dryer operates on the "contra-flow" principle, the drying and heating of the stone being effected by introducing the hot gases into the dryer at the discharge end instead of at the feed end. They pass out at the feed end of the dryer by means of the same exhaust fan. This arrangement ensures that the aggregate is dried at the cooler end of the drum and then passes through the hottest gases as it is discharged. The one exhausting fan is employed for reasons of economy, but the feed and discharge ends are connected to the fan by means of ducting, and dampers are provided so that the fan can draw either from the feed end or discharge end according to whether the high or low temperature process is in operation.

The apparatus for controlling the discharge of the dust consists of special doors fitted in the discharge chambers at each end of the dryer. The effect of opening either of these doors is to increase the velocity of the gases passing through the dryer, thus drawing off the lighter dust. If both doors are kept closed, all the fine material is retained in the drum. The combustion chambers are each provided with cleaning doors, through which a straight-through raking tool can be used.

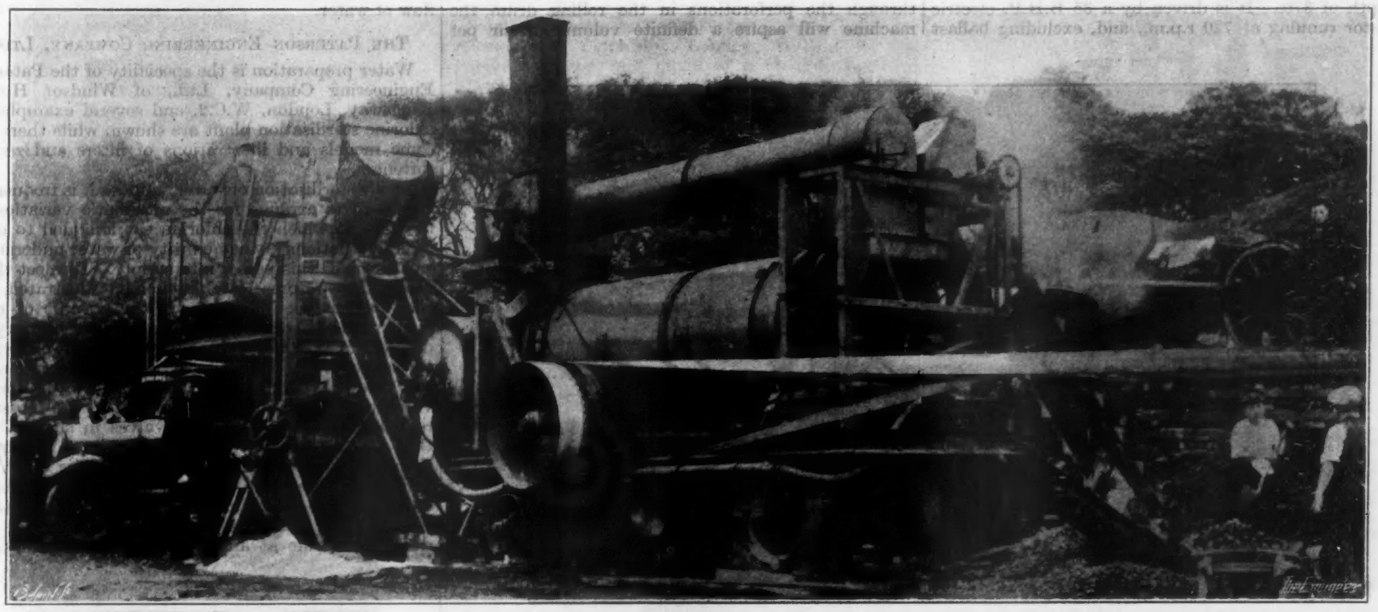

FIG. 23—PLANT FOR MAKING TAR-MACADAM AND ROAD-SURFACING MIXTURES—MILLARS

The combustion chambers are constructed of steel plate stiffened with steel angles. The feed end chamber is arranged to receive the feed spout and the discharge end chamber is provided with a discharge hopper built of steel plate and fitted with a discharge door of the gate type. At each end of the plant the upper portion of the combustion chambers is arranged to receive the steel ducting connecting up to the fan. The combustion chamber at the feed end is fitted with a special fire-brick chamber to suit the oil burner, and the chamber at the discharge end, being larger, is lined with fire-brick. Each combustion chamber is fitted with one oil burner—a No. 10 size at the feed end and a No. 20 size at the discharge end. Under certain conditions it is necessary for the feed end burner to be fitted alongside the No. 20 burner at the discharge end in order to secure the necessary temperatures. The oil is atomised by compressed air at a pressure of 3 lb. per square inch, the air being derived from a blower mounted on the main frame. A fuel oil supply tank is mounted on the main frame, with a fuel level indicator and semi-rotary hand pump for filling. The oil is delivered to the burner at either end of the dryer under a pressure of 4 lb. per square inch, the air being taken from the blower which also supplies the air for the atomisation of the oil. The tank is completely covered and is readily accessible.

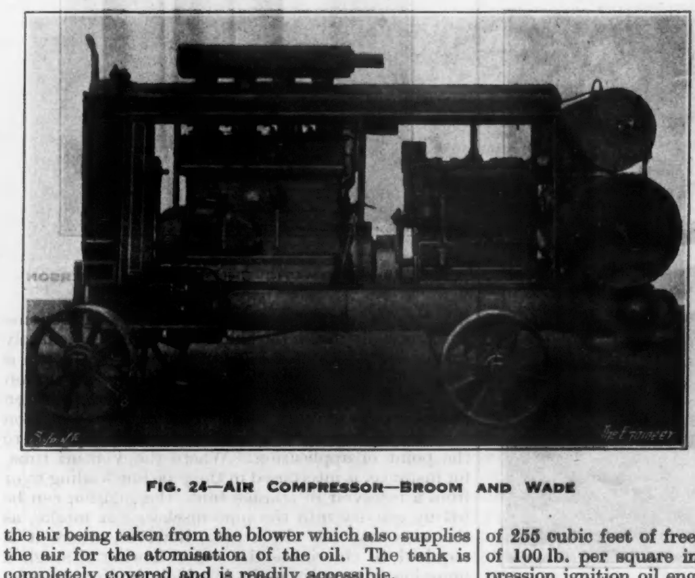

FIG. 24—AIR COMPRESSOR—BROOM AND WADE

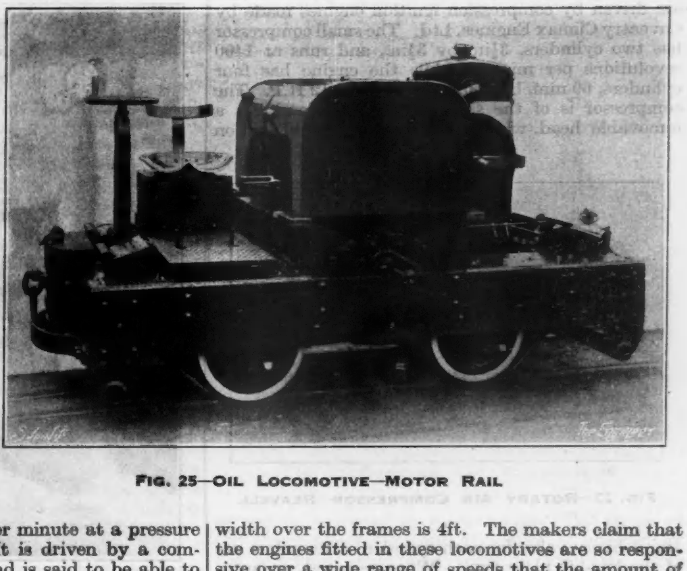

FIG. 25—OIL LOCOMOTIVE—MOTOR RAIL

The drying drum is 4ft. in diameter by about 12ft. long and is constructed of steel plate, ¼in. thick, fitted with steel lifters and semi-diaphragm plates for breaking up the flow of the gases. It is mounted on cast steel tyres and supported on cast iron rollers fitted with gun-metal bushes mounted on steel axles. The axles are provided with adjusting screws to facilitate the alignment of the drum and to ensure smooth working. Vertical thrust rollers are fitted at the feed end to ensure that all expansion of the drum is passed on to the discharge end. The drum is lagged with asbestos mattresses and covered with light steel sheeting to protect the lagging from the weather. The fan is of the centrifugal type and driven by a Renold chain and sprockets from the main countershaft of the plant.

The feed elevator is of the intermittent type with buckets of malleable iron. A small hopper built of steel plate is arranged to take the discharge from the dryer and is fitted at the lower end with a hinged balanced closing door so that the dried material can be retained in the hopper as desired and be discharged at will into the loading skip of the mixing unit or into the boot of a hot elevator.

The chassis of the stationary model is fitted with cast iron cup and ball bearings at the discharge end, while the feed end has cast iron brackets provided with cast iron wedges, by means of which the inclination of the dryer can be varied to suit the material being dried. The portable model is mounted on four road wheels having steel treads, steel centres, and heavy cast iron hubs. The axles are of mild steel turned from the solid, and the front axle is mounted on a swivelling forecarriage and provided with draw gear. The machine requires about 15 horse-power.

On this stand there are also some concrete mixers, trucks, and other contractors' plant.

BROOM AND WADE, LTD.

A new air compressing unit is being shown on the stand of Broom and Wade, Ltd., High Wycombe. It is illustrated by Fig. 24, and has an actual delivery of 255 cubic feet of free air per minute at a pressure of 100 lb. per square inch. It is driven by a compression ignition oil engine, and is said to be able to run for a full eight-hour day at a cost of only 9s. for fuel and lubricating oil, which is about a quarter of the running cost of a similar petrol-driven set.

The compressor is of the makers' sleeve valve type, which we have described in the past, and has three cylinders, 6¼in. bore by 5¼in. stroke. It runs at a speed of 1000 revolutions per minute, and has a piston displacement of 303 cubic feet per minute. There is an air governor for unloading the compressor when the working pressure is reached, and an air receiver, 2ft. in diameter by 3ft. 9in. long. It is tested to a pressure of 190 lb. per square inch, and is equipped with the usual fittings. The aftercooler pipe is fitted with four cocks for ¾in. hose.

The engine is a Ruston four-cylinder set of 70 horse-power, and has both hand and compressed air starting gear. The drive is direct through an automatic centrifugal clutch. Air filters are fitted to the intakes of both the engine and the compressor. One radiator is used for cooling the engine and compressor, but the two units have separate pumps. A sheet steel housing is provided with detachable sides. The weight of the complete plant is about 4 tons 6 cwt.

There are half a dozen other air compressors on this stand, ranging from 20 cubic feet per minute upwards, and a collection of pneumatic tools.

MOTOR RAIL, LTD.

Three oil-engined locomotives are to be seen on the stand of Motor Rail, Ltd., Simplex Works, Bedford, one of which we illustrate in Fig. 25. They are intended for working on 2ft. gauge railways, and are of 2½ tons weight. One is equipped with a 12–16 B.H.P. compression ignition engine, another with a 20–28 horse-power engine, while the third is an old-type Simplex petrol locomotive which has been re-equipped with a high-speed British oil engine.

The locomotive which we illustrate has a wheel base of 3ft. 4in., and an overall length of 9ft. 0¼in. The wheels are 1ft. 5¾in. in diameter and are all drivers. The final transmission of the drive is effected by chains. The height to the platform, above the rails, is 1ft. 8½in., and the rail clearance 2¾in. The total width over the frames is 4ft. The makers claim that the engines fitted in these locomotives are so responsive over a wide range of speeds that the amount of gear changing necessary is reduced to a minimum. The radiators are the "Davies" detachable tube type, and are unaffected by vibration and shocks, and can readily be dismantled in case of damage.

STOTHERT AND PITT, LTD.

There are several appliances on the stand of Stothert and Pitt, Bath, which are somewhat novel, and among them there is the excavator illustrated in general arrangement by Fig. 26, which shows a larger size of the same machine.

The actual machine at the Show has an output of 30 cubic yards per hour, dependent on the material to be handled, and is capable of excavating to a vertical height or depth of approximately 14ft. The ladder can, however, be increased in length to dig a height or depth of 20ft. It is driven by a twin-cylinder Lister oil engine of 9½ H.P., running at 750 r.p.m., and the weight of the total equipment is approximately 8 tons *ex* ballast. The machine shown in the accompanying illustration is one of a larger size, capable of digging 60 cubic yards per hour actual output, and is shown working on gravel and sand. In this case the unit has to deal with a 7ft. depth of overburden, and is capable of digging a 30ft. vertical depth of gravel and sand, making a total vertical depth of 37ft. It is driven by a 35 B.H.P. electric motor running at 720 r.p.m., and, excluding ballast the approximate weight is 27 tons. This particular unit has excavated over 150,000 cubic yards of material, and on a number of occasions an output of over 100 cubic yards per hour has been recorded by the makers.

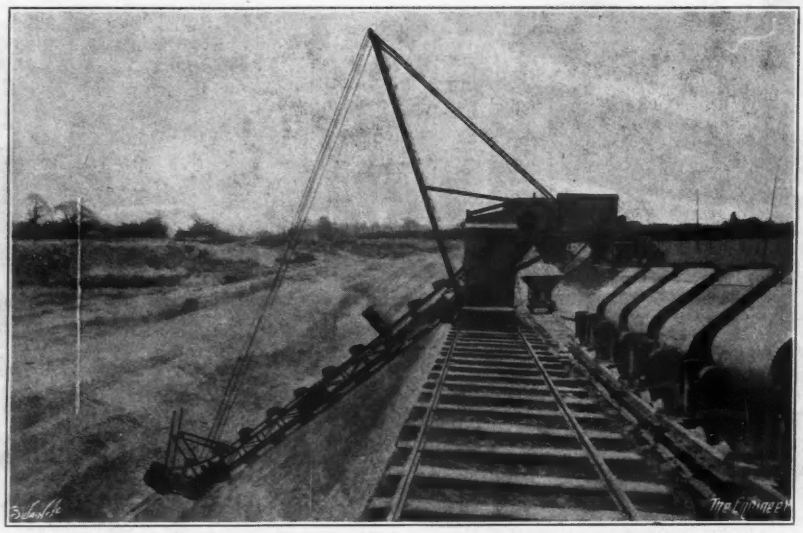

FIG. 26—MULTI-BUCKET EXCAVATOR—STOTHERT

There are also several other machines on this stand, including a vibratory screen which embodies, in addition to the vibratory action, an oscillating action produced by means of excentrics running in ball bearings in conjunction with spring suspenders. It is suitable for all screening problems, such as coal, coke, stone, &c., and can be designed for any output and number of gradings. Other machines include some concrete mixers, a hot mixer for tarmacadam work, and a portable telescopic mast and winch for general contracting work.

REAVELL AND CO., LTD.

A range of air compressors with capacities from 54 to 148 cubic feet is shown by Reavell and Co., Ltd., of Ranelagh Works, Ipswich, the newer types of which are driven by compression ignition engines made by Coventry Climax Engines, Ltd. The small compressor has two cylinders, 3¼in. by 3¼in., and runs at 1400 revolutions per minute, while the engine has four cylinders, 69 mm. by 100 mm. It gives 12 H.P. The compressor is of the single-acting type, and has a removable head, which contains a combined suction and delivery valve for each cylinder. The valves are of the low-lift plate type. When required, an automatic unloading device can be fitted. This unloads the compressor when the air in the receiver reaches the maximum pressure and reloads it when the pressure falls to a predetermined minimum. Immediately after unloading, air is admitted to a throttle control which automatically slows down the engine to an idling speed, and when the minimum pressure is reached the engine is again speeded up prior to the compressor being reloaded. This device results in a great saving of fuel and materially lengthens the life of the machine.

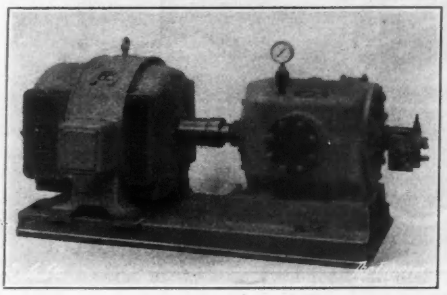

FIG. 27—ROTARY AIR COMPRESSOR—REAVELL

The rotary air compressor shown in Fig. 27 is of what is known as the rolling drum type, which avoids the wear of the rotating blades unavoidable in the old form of "crescent" compressor. Inside the bore of the casing there is a free drum, ground to fit accurately, and having a number of perforations. This drum runs in roller bearings in the end covers of the casing. Inside the rolling drum and running excentrically to it is an accurately machined rotor, provided with sliding blades in the usual way. When the rotor begins to revolve the centrifugal force generated in the blades causes them to press against the inner surface of the rolling drum, and the latter, being perfectly free to rotate, is at once carried round by the pressure of the blades. As air can pass freely through the perforations in the rolling drum the machine will aspire a definite volume of air per revolution and compress it just as positively and efficiently as if the blades pressed against the stator or casing itself. The shaft of the rotor is carried on ball bearings at each end, and as the only moving parts are the rotor and the rolling drum, which rotate on ball and roller bearings respectively, and the sliding blades, it will be realised that the mechanical efficiency of these machines is very high. These machines are made in several sizes for delivery pressures from 5 lb. to 20 lb. per square inch and for deliveries up to 2220 cubic feet per minute.

ELECTROFLO METERS COMPANY, LTD.

The most recent development shown by Electroflo Meters Company, Ltd., of Abbey-road, Park Royal, is the application of the electrically operated flow meter to the measurement of flows through Venturi flumes and over either rectangular or notched weirs. This meter, which we have described in the past, depends, it will be remembered, on the immersion of an electrical resistance in a bath of mercury, and the consequent variation in the current passing. In the original meter, the mercury is raised and lowered by a differential pressure round about a fixed resistance element, but in the new meter for flumes, which is illustrated by Fig. 28, the arrangement is reversed and a balanced float is used to raise and lower the resistance element in the mercury. An advantage of this arrangement is that the meter can be surmounted, as shown in the engraving, by a local height and rate of flow indicator.

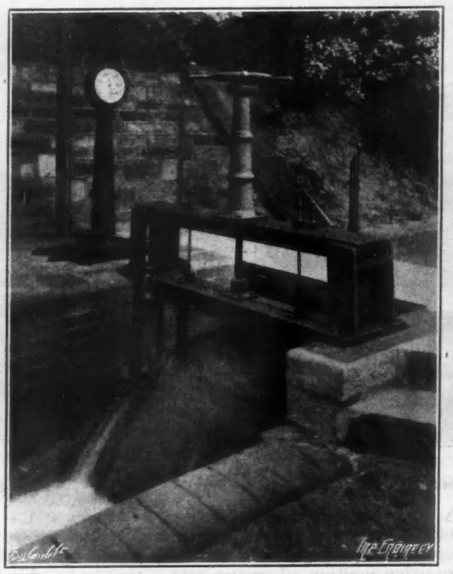

FIG. 28—FLOW METER—ELECTROFLO

Another quite recent development is the Electroflo Lineagraph. The main feature of this is a 12in. wide single-pen continuous recorder, which is driven horizontally across the full width of the chart. The chart has rectangular co-ordinates, and lasts for approximately three months, while the chart extension slide exposes a full unobscured record of one week's operation. It will be remembered that we recently reprinted in THE ENGINEER (April 21st, 28th and May 5th, 1933), a paper by Dr. F. V. A. E. Engel, of this firm, on his researches on non-uniform flow of water.

THE PATERSON ENGINEERING COMPANY, LTD.

Water preparation is the speciality of the Paterson Engineering Company, Ltd., of Windsor House, Kingsway, London, W.C.2, and several examples of chlorine sterilisation plant are shown, while there are some models and illustrations of filters and zeolite softeners.

In the sterilisation of water supplies it is frequently necessary to arrange for the automatic variation of the rate at which the chlorine gas is added to cope with fluctuations in the quantity of water undergoing treatment as this passes into supply. To meet these cases the automatic chloronome, illustrated by Fig. 29, has been devised for the purpose of controlling the chlorine flow by means of the varying differential head set up by a fluctuating flow of water through a Venturi tube. In the automatic chloronome this pressure difference is utilised to operate a special valve which combines the functions of the pressure-reducing and flow-regulating valves in such a way that an increase of water flow produces a proportionate increase of chlorine gas, and *vice versâ*. A particularly sensitive type of manometer indicates on a scale the rate of chlorine addition at any time. A regulating valve is provided for adjusting the dose of chlorine at any predetermined rate. Once this required dose has been decided, the chloronome automatically varies the chlorine flow proportionately to the flow of water. After measurement, the gas is passed through a moisture seal into an absorption tower, where it is converted into an aqueous solution discharged by gravity at the base of the absorption tower, and conveyed by chlorine-resisting piping to the point of application. Where the Venturi tube, for instance, is interposed in the pipe line leading to or from a reservoir or storage tank, the solution can be fed by gravity into the pipe discharge or intake, as the case may be. In a case, however, where it is required to chlorinate the water flowing through a pumping or pressure main, in which the Venturi tube is situated, as, for example, in the outflow from pressure filters, a pump of special design must, of course, be installed for injecting the chlorine solution against the head of water in the pipeline.

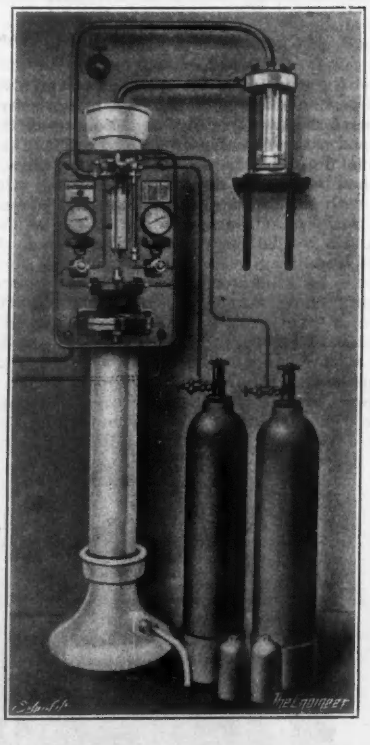

FIG. 29—AUTOMATIC CHLORONOME—PATERSON

A particular feature of the chloronome is the moisture seal interposed between the control panel and absorption tower. This seal, by preventing the entrance of moisture to the fittings on the control board, obviates any corrosion which would inevitably occur were the chlorine gas to become damp.

A recent development in this connection is a gaseous chlorine administrator combined with means for showing the actual quantity of chlorine being applied at any time, and giving a permanent record on a chart. The Chlorograph consists essentially of an orifice type flow meter connected to a glass "U" pattern manometer tube provided with a silvered scale which is calibrated to read the flow of chlorine in terms of the weight of the quantity of gas passing per hour. The recording mechanism consists of a special diaphragm chamber which is connected to the flow meter, and to a metallic aneroid cell. Fluctuations of pressure due to variation of flow through the meter are transmitted by means of a special liquid from the diaphragm chamber to the aneroid cell, and a pen arm coupled to this cell by a lever system records the variation of flow on a chart driven by a seven-day clock.

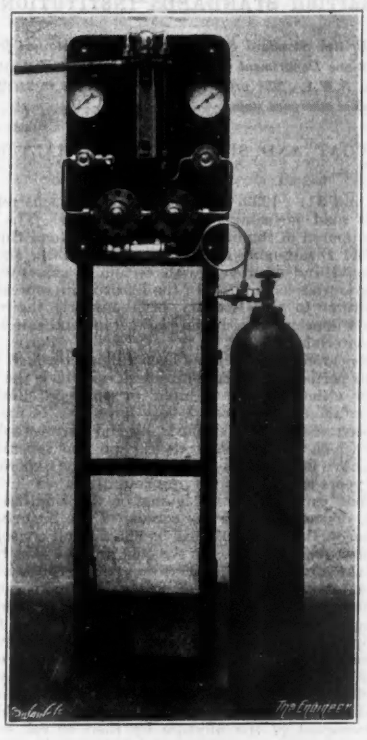

Fig. 30—Gaseous Ammoniator—Paterson

An apparatus for the addition of ammonia gas, before or after chlorine, to potable water, to ensure its being tasteless, is shown in Fig. 30. It acts on the same general principles as the Chloronome.

W. H. Dorman and Co., Ltd.

There are four oil engines and two petrol engines on the stand of W. H. Dorman and Co., Ltd., Stafford. They range from 15 to 86 horse-power in the case of the oil sets and from 24 to 55 horse-power for petrol.

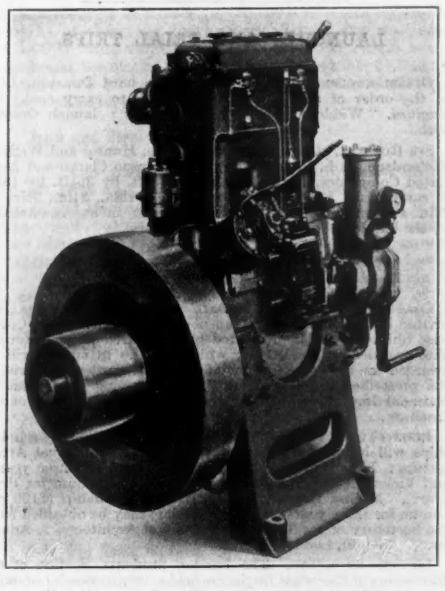

Fig. 31—15 H.P. Oil Engine—Dorman

We have chosen the smallest set for illustration in Fig. 31.

It is a two-cylinder engine of Ricardo type with cylinders 110 mm. in bore by 180 mm. stroke and it runs at 600 r.p.m. The cylinders are cast in pairs and have liners of nitrided cast iron. The cylinder heads are detachable and the whole assembly, head, block, and crank case, is held together by through bolts. The pistons are of aluminium alloy. The fuel pump is of Bosch make. The valves are overhead and are operated by rockers and a cam shaft in the crank case. The engine will run satisfactorily on paraffin, gas oil, solar oil, and any Diesel grade of fuel oil having a viscosity about 50 seconds Redwood at 100 deg. Fah. The power of the engine is obtained at or about sea level with fuels having a calorific value of about 19,500 B.Th.U. per pound gross. The fuel consumption at full load is 0·45 pint per B.H.P. hour on an average Diesel grade of oil.

The Consolidated Pneumatic Tool Company, Ltd.

All the plant and tools on the stand of the Consolidated Pneumatic Tool Company, Ltd., Egyptian House, 170, Piccadilly, London, W.1, is of the pneumatic type, and much of it is quite familiar. There are, however, some new features about the oil-engine-driven portable compressor exhibited. It is driven by a Dorman-Ricardo engine, and the compressor is fitted with the usual type of unloader, which comes into action when the receiver is fully charged with air. At the same time, the unloader acts on the engine governor to reduce the speed and save fuel as much as possible. The compressor has cylinders 5¾in. by 5in. and runs at 800 revolutions per minute. Its piston displacement is 120 cubic feet per minute, and the delivery pressure is 100 lb. per square inch. The engine has four cylinders, 4in. by 5in., and is designed to run on Diesel oil.

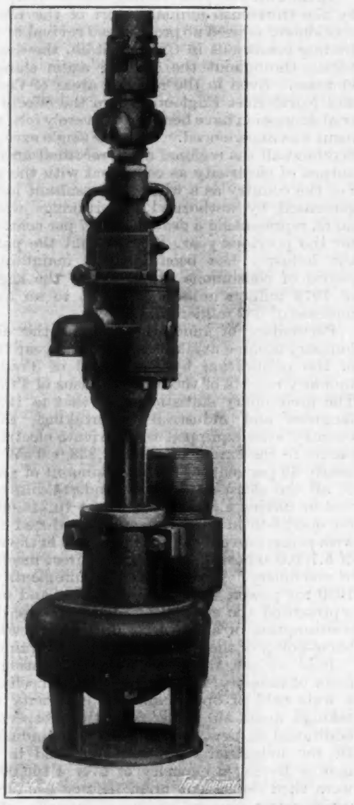

Fig. 32—Air Motor-Driven Sump Pump—Consolidated Pneumatic

The little sump pump illustrated by Fig. 32 has been brought out for such services as pumping surplus water from manholes, ditches, tanks, &c., and is driven by a rotary air motor. It is made in two sizes, one capable of pumping 145 gallons per minute against a head of 20ft., or 130 gallons against 30ft. The other set will raise 205 gallons per minute 20ft., or 175 gallons 30ft. The air pressure in each case is 90 lb. per square inch.

George Kent, Ltd.

Water-measuring and recording instruments of various kinds are exhibited by George Kent, Ltd., of Luton, and include the flow transmitter shown in Fig. 33, which is of the mercurial type, and is operated by the differential pressure produced by an orifice plate. In this transmitter a contact arm is rigidly attached to the gland spindle, which is operated by the float in the mercury chamber. The contact arm moves across a closely wound former immersed in oil. This coil or former is fed with an electrical supply through an iron resistance regulator, which maintains the current value constant. The voltage between the moving contact arm and one end of the coil is impressed on the receiving instrument, which is generally of the voltmeter pattern.

For the purposes of demonstrating the measurement of water flows, an installation has been arranged in which water is circulated by means of a pump. The water flows through a Venturi tube, over a weir plate, and through a flume. The flow through the 3in. Venturi tube is recorded on a mercurial recorder, which has a drum-type recorder 19in. long with a pen travel of 10in. The range of registration is approximately 1 to 14, and the accuracy within 1 per cent. at all normal rates of flow. The counter is constructed to give a ten-minute integration. After passing the Venturi tube the water is raised to a weir tank equipped with a V notch, and the head of water over the weir indicated by a dial indicator. Finally, the water runs down a Venturi flume at the rate of about 8000 gallons per hour. This flow is recorded by taking a pressure pipe from the upstream side of the flume to the float chamber. Above this float chamber and operated by the float there is mounted a recorder showing on a drum chart the rate of flow through the flume. This chart has a length of 11½in., a pen travel of 4in., and is equally spaced. The recorder has a range of registration of 1 to 30, and is fitted with a continuous integrator. There are also on this stand a number of instruments for recording at a distance flows, pressures, and levels.

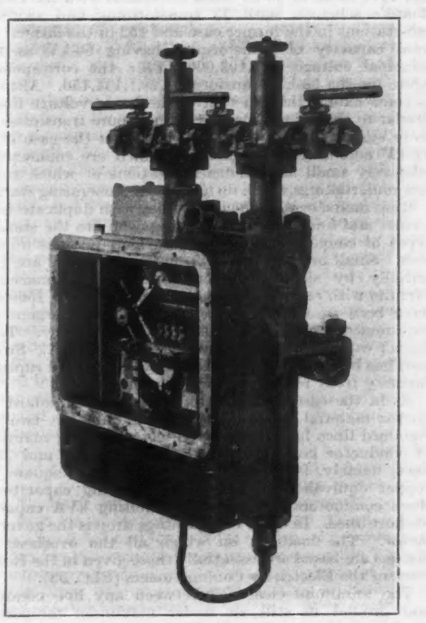

Fig. 33—Electrical Flow Transmitter—Kent

Blackstone and Co., Ltd.

There are a number of oil engines on the stand of Blackstone and Co., Ltd., Stamford, ranging in size from 10 to 60 horse-power in high-speed vertical sets, and up to 55 H.P. in horizontal form. They are of the compression-ignition type, and are fitted with the spring injection system with which our readers are familiar. In the case of the vertical engines the new C.C.C. system of pump injection for the fuel is used. In this each cylinder has its own pump, driven by a common cam shaft, and connected to the spray by a short pipe. The stroke of the pump is constant and regulation is effected by the governor by-passing some of the fuel. The arrangement is said to ensure a sharp opening and closing of the spray valve, so that there is no risk of dribbling at the beginning and end of the injection period.

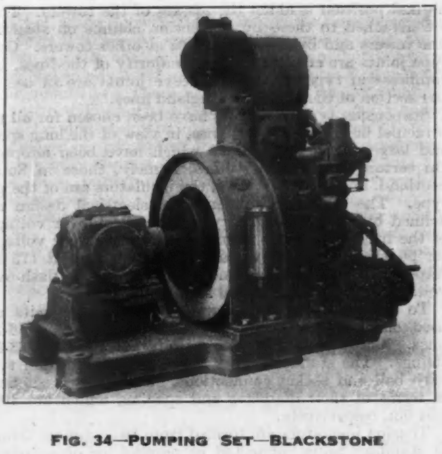

Fig. 34—Pumping Set—Blackstone

The 3in. pumping set shown in Fig. 34, which is driven by one of these engines, is shown running. The pump is of the Unchokeable type, which we have already described, but has a vertical spindle and is driven through the gear-box seen mounted on the bed-plate. The demonstration shows plainly how the pump can handle gravel and even small boulders without damage.

(To be continued.)

Grid Secondary Lines.

The lower-voltage sections of the British Grid System formed the subject of a paper read on Thursday, November 9th, by Mr. C. W. Marshall before the Institution of Electrical Engineers. Lines which operate at 66 and 33 kV are the principal sections of the grid considered, the few sections working at 22, 11, and 6·6 kV being relatively unimportant. There are 221 circuit miles of 66-kV lines and 1319 miles of 33-kV lines associated with the Central Board's schemes, with 33 transforming and switching sub-stations in the former case and 152 in the latter. The total capacity of transformers having 66-kV as their principal voltage is 1,193,000 kVA; the corresponding figure for the 33-kV transformers is 1,134,450. Although to some extent the function of the lower voltage lines is similar to that of the main grid lines, pure transmission is more closely approached, particularly in the case of the 33 kV and lower voltage lines, which are connected to relatively small and inefficient stations or which supply new undertakings which do not possess generating stations.

Ring mains or double-circuit lines with duplicate transformer and line supplies to each station are the standard types of connection wherever the load justifies duplication. Small or relatively unimportant supplies are given initially by single line and transformer connections. Circuits with capacities ranging from 40,000 to 1500 kVA have been provided to meet the widely divergent load requirements of different parts of the country. Transformer capacities range from 45,000 to 50 kVA. Switchgear has been used of practically every standard rupturing capacity from 1·5 million kVA downwards.

As in the case of the 132-kV lines, the standard conductor material is steel-cored aluminium, but two non-standard lines have copper conductors. Four main sizes of conductor have been used for the 66-kV and 33-kV lines, namely, 0·175, 0·15, 0·1, and 0·075 square inch copper equivalent. The current-carrying capacities of these conductors determine the limiting kVA capacities of short lines. In other cases voltage drop is the governing factor. The loadings on which all the overhead line designs are based are essentially those given in the Regulations of the Electricity Commissioners (El.C. 53).

The minimum clearance between any line conductor and ground in still air under maximum temperature conditions (50 deg. Cent.) is 20ft.; that for any earth conductor under the same conditions is 17ft. More stringent clearance or constructional conditions are imposed at certain classes of crossings. The normal span length for the various classes of lower voltage lines varies from 900ft. for 0·175 square inch steel-cored aluminium conductor lines to 400ft. for 0·1 square inch copper conductor lines. The maximum allowable span length on standard supports is 35 per cent. greater than the normal span for the line.

Standard angle supports are so designed that, when used with the maximum angles of deviation, the sum of two adjacent span lengths may, where ground contours permit, exceed by 10 per cent. twice the normal span lengths. The steel core is galvanised, and in cases where the conductor has only one layer of aluminium strands the core is coated with bitumastic compound before the aluminium wires are laid on.

After the lines have been put into service, resistance tests are made on each conductor, using currents of the order of full load. Thereafter control tests are carried out, at intervals of a year, on sections of conductors on lines in industrial areas where atmospheric pollution is abnormal and on others which are close to the sea coast.

Interlocked-strand steel-cored aluminium conductors have been used experimentally on a short section of 66-kV lines in North-East England. This type of conductor has the advantage of considerably reduced overall diameter and improved anti-corrosion properties.

Earth conductors are, except in a few specifically mentioned cases, of the same materials, and manufactured to the same specification as the line conductors. Their normal position is along the apexes of the towers. They are attached to these by suspension clamps on straight-line towers and by tension clamps at other towers. Cone type joints are employed in the majority of the lines, but compression type aluminium sleeve joints are in use on one section of the Mid-East England lines.

Suspension type insulators have been chosen for all the principal 66-kV and 33-kV lines, in view of the long spans and large conductor sections which have been adopted. On certain of the 33-kV lines, namely, those in South Scotland, and on 11-kV lines, the insulators are of the pin type. The basic requirements for electrical design are defined by the minimum dry and wet flash-over voltages of the insulators. The minimum dry flash-over voltages for 66-kV and 33-kV insulators are 280 kV and 175 kV respectively. The corresponding minimum wet flash-over voltages are 170 kV and 100 kV.

To meet these requirements, five insulator units are used on both suspension and tension strings on 66-kV lines. Correspondingly, three units are used on 33-kV strings. The standard units are of the cap-and-pin type with ball and socket connections. They may be defined in terms of their diameter and spacing, which are 10in. and 5in. respectively.

Tension insulators are formed from two or more strings of standard units connected in parallel, or of strings of special high-strength units, as may be required by mechanical considerations. Provision is made on the towers for fitting one additional standard insulator unit per string to provide against exceptionally onerous atmospheric conditions.

Arcing horns are fitted to the conductor clamp fittings of all suspension and tension insulator strings with the object of protecting insulators and conductors from the action of power arcs. So far, it has not been necessary to use special anti-fog or anti-dirt insulators on lower-voltage lines, but on certain lines immediately adjoining the sea coast the maximum number of standard insulators has been provided from the outset.

Lattice steel towers are standard for all the Board's 66-kV lines. They have also been used for all 33-kV lines, with one exception. In this case centrifugally cast concrete poles have been used as straight-line and medium-angle supports.

Standard towers are of the narrow-base type for small and medium-angle positions. The main members of these towers slope uniformly from base to top. Large-angle and terminal towers are of the broad-base type, with main members sloping uniformly from the base to the middle cross arm. The line conductor disposition is triangular on single-circuit towers and hexagonal on double-circuit towers, with the earth conductor at the apex.

Other sections of the paper cover foundations, earthing, tower tests, special constructions at crossings, underground cables, switching and transforming stations, and protective equipment. One of the most interesting statements made in connection with tapping the lines is that for the smallest connections transformers are teed off directly to the supply line through isolating and earthing switches, with or without protective fuses in the transformer primary circuit. Fuses have been introduced in these cases only when it is essential to disconnect the transformer locally in order to preserve continuity of supply on other circuits, for the Board's experience has shown that transformers may be directly connected to 33-kV lines without impairing reliability.

The Electricity Commissioners' Report.

Although the year ending March 31st, 1933, covered by the thirteenth annual report of the Electricity Commissioners, showed no pronounced revival in industrial and trading conditions in Great Britain, the demand for electricity throughout the country again showed a notable increase. Even in the regional areas of Central Scotland and North-East England, where the effects of the industrial depression have been most severely felt, some improvement was experienced. With the single exception of North Scotland all the regional areas recorded an increase in the output of electricity as compared with the previous year. For the country as a whole the resultant increase in units generated by authorised undertakings was 897 million units, representing a growth of 7·7 per cent. on the output for the previous year. Throughout the past three years the industry has been able to maintain an enviable record of continuous expansion to the aggregate extent of 1979 million units, equivalent to an average annual increase of 659 million units.

Particulars of much interest to the electric supply industry became available during the year 1932 as a result of the publication by the Board of Trade of the preliminary reports of the fourth Census of Production, 1930. The preliminary statistics show that in 1930 the various factories and industrial undertakings throughout the country were equipped with private electrical generating plants to the extent of about 2,833,000 kW (equivalent to nearly 40 per cent. of the total amount of generating plant in all the electricity supply undertakings), with electric motors having a capacity of about 10,244,000 horse-power for operation in part by factory produced electricity, and with prime movers having a capacity in the neighbourhood of 6,700,000 horse-power for the direct mechanical driving of machinery. The electrical requirements of industry in 1930 for power, inclusive of lighting and other purposes, represented the equivalent of an average demand for or consumption of about 1022 units of electricity for every horse-power of the total electric motor equipment installed.

It is evident, therefore, that the existing power equipment of industry, both electrical and mechanical, presents a wide field of opportunity to electricity supply undertakings, apart altogether from the prospects arising from additional or new uses of power for industrial purposes. Of the industrial equipment installed in 1930, electric motors having a capacity of over 4,100,000 horse-power were then dependent upon factory produced electricity, while prime movers having a capacity of the order of 6,700,000 horse-power were installed for direct mechanical drive. This equipment thus represents a potential addition of over 10,000,000 horse-power to the existing industrial load on the public supply systems as and when the factory generating plant and prime movers become obsolete.

Inclusive of the Central Electricity Board and allowing for the case of two companies with undertakings in England and also in Scotland, the number of separate undertakings at March 31st, 1933, was 650, a net decrease of ten on the number holding supply powers at the end of the preceding year. There were also four other statutory bodies not possessing powers to supply, but charged with definite duties of an advisory or supervisory character in respect of the organisation for the supply of electricity in districts within their jurisdiction.

The returns of units generated and fuel consumption, &c., rendered to the Commissioners in respect of generating stations of all authorised undertakers in Great Britain, including the voluntary returns in respect of all generating stations owned by railway and tramway authorities and of certain stations owned by non-statutory undertakings, are summarised in a table covering the year ended December 31st, 1932. The units generated showed a resultant increase of nearly 843 million, or 6·6 per cent., on the figures for 1931, the larger output being accomplished by an increase of 243,584 tons, or about 2·5 per cent. increase, in the amount of coal and coke consumed, and also by a small increase of 3575 tons in the amount of oil fuel used at generating stations as compared with the previous year.

The stations of authorised undertakers were responsible for an increased output of 831 million units, a growth of nearly 7·3 per cent. on the corresponding figure for 1931, public authority undertakers accounting for an increase of about 585 million units and company undertakers about 246 million units. The output from the stations of railway and tramway undertakings showed a falling off of over 9 million units, but in the case of the stations of the non-statutory undertakings included in the returns there was an increase in output of over 21 million units.

The progressive improvement in steam power station practice during the past three years alone is shown by the fact that the average number of units generated in the stations of authorised undertakers per ton of coal and coke consumed increased from 1200 units in 1930 to 1249 units in 1931 and to 1299 units in 1932.

A table showing the sales of electricity in Great Britain by authorised undertakers during the year ending December, 1932, together with comparative figures for previous years, indicates that during the last calendar year the units disposed of amounted to 10,096,966,827, an increase of 710·2 millions on the previous year. On the basis of the estimated population of Great Britain in 1932, namely, 45·08 million inhabitants, the sales of electricity from public sources of supply in that year represented an average consumption of approximately 224 units per head of population.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

TWO-COAT AND SINGLE-COAT ASPHALT (COLD PROCESS).

510 and 511—1933. These two specifications relate to asphalt road surfacing by the cold process. The drafts were prepared in the first instance by the Road Emulsion and Cold Bituminous Roads Association, Ltd., and were considered and approved with certain modifications, by the appropriate committee of the Institution, representing, in addition to the Ministry of Transport, the various interests concerned with the production and purchase of road materials.

Much careful research has been carried through with a view to perfecting asphalt processes, in which the use of heat is either greatly reduced or entirely eliminated. Both at home and abroad a very large area of roads has now been successfully surfaced by the various cold processes which have been evolved, and the specifications which have now been issued consolidate the experience of many years and widely varying conditions.

In hot asphalt the hardening of the mixture is, of course, dependent upon the cooling of the bitumen; for this reason the mixture must be spread and consolidated soon after manufacture. In the cold processes the hardening of the mixture is dependent upon other considerations, such as the evaporation of water, the evaporation of volatile oils, or the amalgamation of oil and bitumen. By making use of these features, those responsible for the development of the cold processes have introduced materials which not only require the minimum of heat (if any) during their manufacture, but which may be so controlled that the spreading and consolidation may be carried out when desired with the mixture in a cold state. The transport of the mixture by road or rail for long distances becomes possible, and its storage for use when needed is a practicable proposition.

Owing to the fact that in the so-called cold processes little or no heat is used, relatively inexpensive plants may be employed; excellent work, for instance, can be done with the ordinary concrete mixer, which is already in the possession of most highway authorities and contractors.

The arrangement of the specifications follows the lines of previous road surfacing specifications issued by the British Standards Institution, the first part being devoted to definitions, the second to materials, and the third to construction and workmanship. In a series of appendices are described tests demanded by the specifications. Owing to the variety of processes covered by these specifications the limits laid down are necessarily wide. The intention is that, when inviting tenders, engineers should state the classification and table of these specifications with which tenders should comply, and that the contractors should specify in their tenders the actual gradings and percentages of ingredients of the materials they offer. If this procedure is adopted, tenders will be submitted on a comparable basis and their consideration will be greatly simplified.

LAUNCHES AND TRIAL TRIPS.

Diesel-engined Barge; built by Richard Dunston, Ltd., to the order of the Leeds Corporation; to carry coal. Oil Engines, "Widdop" twin-cylinder 50 H.P.; launch October 20th.

Sir Russell, steamer; built by Swan, Hunter and Wigham Richardson, Ltd., to the order of Stephenson Clarke and Associated Companies, Ltd.; dimensions, 252ft. by 36½ft. by 18ft.; to carry coal. Engines, triple-expansion, 19in., 31in., 51in. by 26in. stroke, pressure 180 lb. per square inch; constructed by the builders; trial trip, November 10th.

Coastwise Shipping Medal, 1934.—Contributions are invited by the Institute of Transport in competition for a Coastwise Shipping Medal, presented by Sir Alfred Read, a former Vice-president. The Medal, which will be in silver, will be awarded for the contribution judged first in order of merit on the prescribed subject, "The British Coasting Trade and its National Importance." The writer must be a member of the Institute.

Institution of Naval Architects.—The following scholarships will be offered for competition in 1934:—Naval Architecture: Elgar Scholarship (£130 per annum for three years), and Vickers-Armstrong Scholarship (£150 per annum for three years). Marine Engineering: Yarrow Scholarship (£100 per annum for three years). Full particulars may be obtained from the Secretary of the Institution of Naval Architects, 2, Adam-street, Adelphi, London, W.C.2.

London Students.—The London Students' Section of the Institution of Electrical Engineers held a very successful smoking concert at Carr's Restaurant on Thursday evening, November 9th. Well over 100 members of the section attended, and among the guests were Mr. P. V. Hunter, President of the Institution; Mr. H. T. Young; Mr. J. H. Heynor, editor of the *Students' Journal*; and student and graduate representatives of the Institutions of Civil and Mechanical engineers.

Williams Prize.—The Williams Prize of the Iron and Steel Institute has this year been awarded by the Council jointly to Mr. D. F. Marshall, of Sheffield, for his paper on "The External Heat Loss of a Blast-furnace," which was presented at the last annual meeting of the Institute in London, and to Mr. A. Robinson, of Scunthorpe, for his paper on "Some Factors Leading to Greater Production from a Steel Furnace," which was presented at the autumn meeting of the Institute held in Sheffield in September last.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Satisfactory Import and Export Figures.

The improvement in the iron and steel trades is reflected in the figures of imports and exports provided by the Board of Trade returns for October. Both imports and exports are up, the total imports for October being 88,854 tons, compared with 80,342 tons in September, whilst the exports total 193,613 tons for October, against 157,367 tons for the previous month. The imports of Continental pig iron are insignificant, but 1679 tons was sent to this country from Sweden. This, of course, relates to special iron. Of the remaining 4486 tons of forge and foundry iron, 2287 tons came from British India. No Continental basic iron was imported in October, and the 3000 tons which came in was Indian iron. It is scarcely surprising, perhaps, in view of the increased demand and the rise in prices in this country, that the imports of semis show an increase over the past three months. In August 20,085 tons of blooms, billets and slabs were imported, and this rose to 24,871 tons in September and to 28,511 tons in October. This, however, is less than half the quantity imported over the corresponding months in 1931 under Free Trade. The increase in the imports of sheet bars has not been so noticeable. Last August 4168 tons came into the country; in September this had risen to 8980 tons, and in October receded to 8626 tons. The imports of girders, beams, and joists show a decline on the past three months from 6015 tons in August to 5933 tons in September, and 4487 tons in October. Compared with the ten months of last year, however, imports are slightly up, being 63,423 tons for this year, 60,790 tons for 1932, and 86,512 tons for 1931. The imports of hoop and strip have increased to 9934 tons for last month, compared with 8668 tons in September. So far as exports are concerned, the figures for pig iron show a decline to 7559 tons, compared with 8138 tons in September. Exports of plates and sheets, not galvanised, last month totalled 8875 tons, an increase of over 2000 tons compared with September. There was also an increase of nearly 1000 tons in the exports of plates and sheets under ⅛in. thick. The exports of galvanised sheets, probably as a result of the Argentine order, jumped from 22,028 tons in September to 41,151 tons in October, whilst the exports of tin-plates were 3000 tons up last month at 34,040 tons. The total quantity of railway material exported also improved during October to 9161 tons, compared with 8386 tons in September.

Machinery Exports.

The exports of machinery during October remained fairly steady so far as tonnage was concerned; but the value was £203,166 higher than in September, being £2,509,603, compared with £2,306,437 in October. Exports of textile machinery in October were valued at £475,670, compared with £385,077 in September. Of this total British India took machinery valued at £153,765, the next largest individual customer being China with £41,870. The exports of prime movers increased in value during October to £266,577, compared with £216,199 in the previous month. Here, again, India took machinery valued at £38,780, whilst the Soviet took £19,243, and British South Africa £17,850. The exports of agricultural machinery, however, were down, the value of the October total being £40,030, compared with £50,787 in September. The value of machine tools for metal working exported during October amounted to £74,625, but for the ten months ending October 31st the value was £1,109,003, less than half the 1932 total for the similar period of £2,674,959. It is interesting to note that during the ten months of this year the exports include one war vessel of 14,026 tons, valued at £225,000, whilst steam vessels numbered seven, of 31,412 tons, valued at £1,579,589. Seventy-two motor vessels were exported of 2427 tons, valued at £114,020.

Iron and Steel Production.

The monthly statement of the National Federation of Iron and Steel Manufacturers upon the production of pig iron and steel shows that the situation is still sound, and that the production of pig iron was the highest since November, 1930. There was no change in the number of furnaces which remained at seventy-four, two having been blown in and two having ceased operations during the month. Although the report does not mention it, of the furnaces blown in, one was at the Carron Company's works and one at the New Cransley Iron and Steel Company, in Northamptonshire. Of those which ceased production, one was at Goldendale, Staffs., and one at Renishaw. The production of pig iron in October amounted to 373,300 tons, compared with 359,700 tons in September and 275,600 tons in October, 1932. The production includes 102,400 tons of hematite, 175,400 tons of basic, 78,500 tons of foundry, and 8500 tons of forge pig iron. The output of steel ingots and castings in October amounted to 668,300 tons, compared with 669,000 tons in September, and 439,800 tons in October, 1932.

The Pig Iron Market.

The most interesting feature of the advance in the price of basic pig iron which was announced recently is the system of rebates which has been introduced. Hitherto official rebates in this department of the industry have been calculated over lengthy periods, but the producers now offer monthly rebates, a concession which consumers are likely to appreciate. To obtain the rebates consumers have to give a certificate that they have not purchased any foreign iron. The rebates are available to consumers of Indian basic iron as well as to users of the home product. The inclusion of the Indian producers in the scheme could not be avoided, since the Tata Iron and Steel Company, Ltd., the only maker of Indian basic pig iron, is closely associated with the British makers, and is a party to an agreement by which the company has an allotment of 60,000 tons for sale in the British market, and under which it observes the British producers' scale of prices. These vary according to the makers' system of zones; but the advance has been general and amounts to 7s. 6d. per ton, the rebate under the conditions mentioned being 5s. per ton. As practically no foreign basic pig iron is being imported, the net increase to consumers will be 2s. 6d. per ton. The advance has been well timed, as the demand is strong on the increased activity in the steel trade. An indication of this is given by the decision of Dorman, Long and Co., Ltd., to re-light a furnace at their Cleveland works, and another at their Acklam plant. Both these furnaces will produce basic iron for their steel works, and it is expected that the whole of the additional output will be absorbed by the firm's steel works. In other districts, also, the consumption of basic iron is on a good scale. In the foundry iron section of the market large orders are rather scarce, as so many users, particularly the important ones, have covered themselves well forward. Deliveries against contracts, however, are on a satisfactory scale. The demand for hematite has increased considerably of late, and business with Yorkshire consumers has been transacted for delivery over the first quarter of next year.

Semi-finished Steel.

The chief characteristics of the market are the strength of the producers' position and the steadily increasing tightness of supplies for near delivery. Although the official rate for British billets of ordinary rolling quality was recently fixed at £5 5s., it is by no means easy to place orders at this figure. The majority of the makers ask £5 7s. 6d., but there are some who stand out for £5 12s. 6d. Continental producers have taken advantage of the opportunity afforded them by the stringency of the position and the higher British prices to advance their quotations. Officially, the increase is said to be 2s. 6d. gold, but actually the full advance does not seem to be insisted upon. An interesting change, however, appears to have been made in the Continental quotations, and the prices quoted in the Birmingham area are now higher than for other districts in Great Britain, which is contrary to the position which ruled until recently. The alteration is probably due to the demand for foreign billets being principally from the Midlands. The demand is principally for 2in. and 2¼in. billets, which are now quoted at £5 10s. d/d for the Midlands and £5 5s. elsewhere. For 2½in. and up the price is £5 8s. d/d Birmingham area. In the case of customers of old standing, or when attractive tonnages are involved, prices are subject to special negotiation. The demand for sheet bars is improving, but is less consistent than for billets. British sheet bars are quoted at £5 5s., and in some cases up to £5 7s. 6d. Continental sellers are asking £5 d/d. An example of the effect of the advance in the price of billets is provided by the increase in the re-rollers' price for strip, which is now £9, the quotation for Continental material ranging from £7 6s. 6d. to £8. The Continental makers, therefore, by raising the price for billets, have forced the strip makers to raise their prices, and, at the same time, have kept their own strip quotations low. The strong demand for semis is said to be the chief cause of Dorman, Long and Co. putting into blast two steel furnaces at their Britannia works.

Finished Materials.

Apart from the rather brighter prospects in the shipbuilding industry, business in the finished steel department is on a sounder basis than at any time this year. The recent expansion in business may not have been so extensive as was forecast for the autumn, but there has been much less irregularity in the demand from the home trade, and the steel works are maintaining a steady rate of operations. Lately export trade in finished steel has shown signs of increasing principally with Empire markets, whilst the home demand has certainly not relaxed, and according to some reports has actually improved during the past fortnight. On the North-East Coast the position is sufficiently encouraging to warrant hopes of more plant being put into operation. The structural engineering side of the business in this district is well employed. The rail departments are fairly busy and recent orders for chairs and fish-plates have been secured from the South African Government. The ship repairing yards are also taking fair quantities of steel. In the Midlands the recent rate of output has been maintained. Although it is said that the constructional engineering industry has not become so active as appeared likely early in the month, it is taking fairly regular supplies. The demand is principally for the lighter classes of steel, and business in strip, small bars, and, to a lesser degree sheets, is expanding. The re-rollers hold their price of £7 for re-rolled small bars excepting when they are competing for a good line with Continental works, who continue to quote £6 9s. 6d. to £6 10s. including duty. The steel works are also well employed on this class of material and quote £7 5s. to £8 5s., the wide variation in the quotation being due principally to the difference in the state of some of the works' order books. Competition from the Continent in the Midlands, however, is not serious, and although angles are quoted at £6 15s. to £6 17s. 6d.; joists, B.S., at £6 17s. 6d. to £6 18s.; and plates, $\frac{3}{16}$in. and up, at £8, the amount of business going abroad is not large.

Scotland, Lancashire, and the North.

Steady conditions continue to rule in the Scottish steel markets, and although the demand for shipbuilding material cannot be considered satisfactory, the prospects of an improvement in this direction have promoted a cheerful tone. The structural engineers in Scotland are not busy, but, nevertheless, a fair volume of steel is finding an outlet through their works. Conditions in the tube industry, however, have improved, and the demand for hot-rolled and solid-drawn tubes is on a good scale. The recent improvement in the demand for sheets has been maintained, and although this is largely confined to the heavy gauges, it has been sufficient to keep most of the tube works well employed. The Canadian open water season is now over, and on the whole has been rather disappointing so far as the exports of Canadian steel are concerned. Re-rollers in Scotland are not experiencing busy conditions, and in most cases are at work only half the week. They have retained their price, however, at £7 5s. d/d Glasgow and £6 15s. for export. Conditions in the Lancashire steel market have improved considerably of late, and one of the most satisfactory features is the expanding demand from the structural engineers. An increased disposition on the part of users to buy forward is the result, probably, of the tendency of prices of uncontrolled steel material to advance. For some time past business in special and alloy steels has been satisfactory. The demand also for small bars and hoops has been increasing and in some cases the delivery times have been extended. The re-rollers in this district continue to quote £7 10s. for small bars, but makers in other districts have taken business in Lancashire at lower figures. One of the disappointing features of the market is the failure of the demand for boiler tubes to increase. Business in this department has been at a low ebb for some time, but recently there were indications which have not been fulfilled that the corner had been turned. Activity continues to rule in the Yorkshire steel trades, particularly in the Sheffield district. Business in alloy and tool steel has been on a particularly good scale. There has also been a good demand for rods for reinforced concrete work. Rather irregular conditions exist at some of the Yorkshire structural engineering shops, but the volume of business arising from the requirements of this section of the industry is not decreasing.

The Copper Market.

In spite of the disturbance to trade created by the American policy of depreciating the dollar, or because of it, good business has been done in electrolytic copper. Most of the consuming markets have bought with freedom, and the producers have been equally ready sellers as the market declined. This is a reversal of the policy they have pursued for some years of trying to maintain the market by limiting their sales when prices fell. In fact, in some quarters the view is held that the unsatisfactory situation which has grown up in the copper market since the war is largely due to the mistaken policy of the copper producers in endeavouring to obtain complete control of the market and to eliminate merchants. In this case also they appear to have changed their tactics, and are now willing sellers to merchant interests. The latter have bought considerable quantities at the recently ruling prices. Another reason, of course, for the American producers' eagerness to affect sales is that they can sell in sterling at a low figure and still make a comparatively good return in American currency. As the exchange value of the dollar declined, the price dropped from £35 5s. to £34 10s. c.i.f. No doubt much of the buying in the United States has resulted from the new tendency in that country to invest in commodities as a hedge against further currency depreciation. However, the producers' quotation as a result of the improved sales, advanced to 8.25 c. d/d, and, according to reports, further increases are expected. The failure of the big copper producers and the Customs smelters to reach an agreement regarding the "code" has not greatly influenced the market, since the whole situation for the time being seems to turn upon the American monetary policy. In Europe there is little confidence in the position, but consumers have taken advantage of the cheap prices and have bought fair quantities. There has also been a certain amount of investment buying from countries still on the gold standard. The London standard market has been much under the influence of conditions in the electrolytic department. Prices have slipped back, although the movements have not been important. Comparatively little speculative interest has been shown in this metal, and the easier tone has resulted in some bulls getting rid of their commitments Nervous markets developed in mid-week owing to the depreciation of the dollar exchange. The electrolytic price dropped £1 to £1 10s. and standard, cash and forward, were £1 16s. 3d. to £1 17s. 6d. lower.

Tin.

A rather brighter tone developed in this market on the renewal of American purchases, which were ascribed by the market to the desire of American buyers to exchange their dollars for commodities. At the same time, it is probable that some of the new buying has been for industrial purposes in the belief that values in this market are more likely to advance than to recede. The sharp break in the dollar price last week, followed by expectations of movements such as those described, were responsible in part for a firmer tone, so that when the buying actually matured the price movements were comparatively narrow. A feature of the market at the moment is the scarcity of prompt metal, which has resulted in a backwardation of £1 to £1 2s. 6d. The stocks of tin in this country are only a little over 11,000 tons, and if buying by the United States develops on a serious scale they may be again materially reduced. This possibility has created some nervousness in the market, although the approach of the New Year, when there will be an increase in exports, has naturally had a steadying influence. The demand from consumers on the Continent has been poor, although there have been some transactions with Italy. Disappointment, however, is felt at the slowness of the Continental markets to develop. The continued fall in the dollar exchange in mid-week resulted in realisations, and prices dropped sharply, £2 10s. for cash and £3 for forward.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

The Rail and Road Controversy.

Before any final plan of combined road and rail traffic organisation can be adopted the fullest data have to be collected concerning the changed conditions of transport and the requirements of railway companies, road haulers and users, and such data are being abundantly provided by reports and statistics collected by the Office Central du Rail et de la Route. The problem is not quite the same as in Great Britain, for geographical conditions in this country, with long distances and a vast network of roads through relatively thinly populated regions, are perhaps more equally favourable to both methods of transport. Nevertheless, long-distance transport is no longer a monopoly of the railways, which have to compete with road haulage even between Paris and Marseilles. The difficulty of conciliating the interests of both methods of traction lies in the fact that the lorry has not yet given the full measure of what it can do in dealing with different classes of goods, for its progress has been rapid, and what it is doing to-day may be largely surpassed in the early future. The railway companies, on the other hand, are making equally rapid progress in adapting themselves to the new condition of things by improving rolling stock, accelerating services, collecting and delivering goods from door to door, and offering every facility to those on holiday or pleasure bent. During this period of progressive rivalry in providing the public with what it needs, and at the same time creating new needs, there can be no question of an amicable collaboration between the railway companies and road haulers. Those engaged in road transport are powerfully organised in a national federation, and refuse to enter into any combination which may place them under the domination of the railway companies. What appeared to be an acceptable arrangement was come to provisionally about a year ago, but the Federation declared that it had nothing to do with the matter, and the agreement was dropped. It is probable that the railway companies would never have had their existence threatened if it were not for the special tax of 32·5 per cent. which the State imposed on passenger fares in 1926. That tax has now been reduced to the previous figure of 12 per cent. One effect of the tax was a considerable diminution in the number of passengers carried. For eight first-class passengers carried in 1913 there is only one in 1933, and that one is almost certainly travelling with a free pass; and for thirty-eight second-class passengers in 1913 there are now only seven. The companies are organising a door-to-door service for perishable commodities at reduced rates, and by so doing they have recovered some of the traffic that was carried by road, though in some cases at the cost of smaller receipts. The case for road haulers is that the lorry has improved transport facilities in districts away from the railways, and has helped to bring prosperity to them, and Monsieur Mariage, managing director of the company which monopolises public passenger transport in Paris and the Department of the Seine, declares that the solution of the problem lies in running services at the highest speed consistent with safety, for which reason the construction of special motor roads is included in the national programme of public works. Meanwhile, the policy of the State is to put a curb upon weights and speeds on the road, and lorry owners are agitating strongly against what they claim to be an attempt to strangle their industry. The requirements of agriculturists and other producers have also been canvassed. Their preference is for the most convenient and economical form of transport, and they refuse to be burdened with extra charges that may follow upon an organisation that aims at conciliating the interests of railway companies and road haulers. It is probable that the State will eventually carry through a plan something on the lines of that proposed by the Compagnie du Nord for creating central railway collecting and distributing centres with the aid of lorries and with the collaboration of private lorry owners.

Public Works.

The importance of carrying out public works for the general well-being of the population influenced the discussions of the International Health Congress which was held in Paris recently. Rural water supply, drainage, electrical and gas distribution would, it was said, provide considerable employment, remunerate capital, improve national health, and increase land and property values. So far as rural electrification is concerned, it has always been argued that a supply of electricity for lighting and power purposes would change completely the conditions of existence in country districts and check the depopulation which threatens the agricultural industry, and at a time when the decline of activity in manufacturing industries is accompanied by the return of quite a large percentage of operatives to the country, where they can always find work, the electrification scheme is undoubtedly rendering good service. Whether the scheme is profitable to all suppliers of electricity is another matter, for rural consumers complain of the cost of current and use it parsimoniously, and the idea of electricity being employed generally for agricultural purposes has so far failed of realisation. The supplying of communes with water is particularly urgent in view of the conditions under which rural populations often live, with water drawn from possibly contaminated sources, while in some areas droughts are almost of normal occurrence. For many years the State has offered financial aid and technical assistance in the carrying out of plans for supplying water to communes, but only 10,657 communes out of a total of 38,000 are provided with such a supply, and the State is at present unable to continue the money grants it has been making to them. The International Health Congress therefore proposed that in the scheme of public works preference should be given to a plan of water distribution by mains from central sources of supply in such a way as to ensure that all the communes throughout the country shall be provided with good water. There is so general an insistence on the programme of public works being put in hand without delay that the Government will have no alternative but to provide the means of financing it. In present circumstances this can only be done by means of a public loan.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

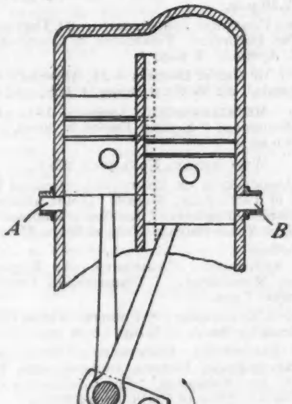
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

INTERNAL COMBUSTION ENGINES.

399,039. November 23rd, 1932.—Two-stroke Engines, M. Y. A. Serruys, 2, Rue Leregrattier, Paris, France.

This is a two-stroke internal combustion engine operating on a cycle in which, even at full load, the mass of fresh gases supplied is not higher than 0·6 of the mass corresponding to the theoretical volume of the cylinders and only part of the burnt gases is exhausted, the remainder of the latter in the cylinder being compressed again with a volumetric compression ratio which is higher than 60 per cent. over the volumetric compression ratio of a usual two-stroke engine, a feeding pump or compressor driven by the engine being provided and so arranged that it is prevented from supplying, even at full load, and at each revolution, a mass of fresh gases higher than the above indicated proportion. The common combustion chamber is shaped as to take advantage of the phase displacement between the pistons at the end of the compression stroke whereby an energetic mixing of the gases is effected at or near the end of the compression.—*September 28th*, 1933.

N°399,039



STEAM GENERATORS.

399,308. September 9th, 1932.—Steam Generators and Desuperheaters, *Babcock and Wilcox, Ltd., Babcock House, Farringdon-street, London, E.C.4.*

The raising of superheated steam to temperatures as high as possible involves, say the inventors, the necessity of again partly or wholly withdrawing from this superheated steam its superheat. Where, for example, the superheating is only to be reduced, this is usually possible by cooling a part of the superheated steam and mixing it with the remaining uncooled steam. Sometimes it is desired to desuperheat a large quantity of superheated steam and to obtain very dry saturated steam. Steam is consequently desuperheated by mixing the superheated steam in a mixing vessel or chamber with a liquid of boiling temperature and leading the mixture through connecting pipes into a separating chamber, from which the saturated steam formed may be withdrawn while the liquid is returned in circulation to the mixing vessel or chamber.) The superheated steam is led by the pipe A into a mixing chamber B. The superheated steam is distributed uniformly over the whole length of the mixing chamber. The steam separating chamber C is connected with the mixing chamber, such steam separating chamber being assumed in the present instance to be a boiler drum. The separating chamber C is only partly filled with liquid and is disposed at such a level that with the normal filling the chamber B is wholly or almost wholly filled with liquid. The two drums are connected by groups of tubes. If superheated steam is introduced through the tube A such steam will mix with the water and force a steam and water mixture into the tubes D, which mixture flows in the direction of the arrows and discharges as steam and water into the drum C. The saturated steam thus formed is withdrawn by the pipe E from the drum and flows to a superheater or consuming device. It may also be mixed with the part of the superheated steam not passed through the cooler. The separated liquid is mixed with the contents of the drum C and flows through the tubes F in circulation back to the mixing chamber B. The water evaporated can be replaced by a feed pipe G.—*October 5th*, 1933.

DYNAMOS AND MOTORS.

398,984. July 19th, 1932.—Dynamo-electric Machines, Gustaf Adolf Juhlin, of "Redscar," Moss-lane, Timperley, Cheshire, Thomas Hadwen Charlton, of 82, Church-road, Urmston, Lancaster, and Associated Electrical Industries, Ltd., of Crown House, Aldwych, Westminster.

An improved form of spider for supporting the rotor laminations of electrical machines is described in this specification. The disc member is formed from a plate of mild steel, and may conveniently be cut to its circular formation by means of a cutting flame. Equally spaced recesses A are cut out from the periphery of the disc B. Small holes C and larger holes D are drilled in the disc to reduce its weight. The disc is mounted on a hub member E constructed of rolled steel tube, and is connected thereto by welds F and G, whilst the hub member is secured to the rotor shaft by a key which is accommodated in a keyway H. Fillets J and K of black steel bar, rolled to the desired diameter, are fitted in the angles between the hub E and the disc B, and are welded to these two parts. In order to stiffen up the disc laterally ribs L are provided on each face of the disc B. They are assembled radially to extend between the innermost portions of the cut-out recesses A, to the outer peripheral surfaces of the fillets J and K, and are welded to these fillets and to the disc B. The rods M, which are of black steel bar, are accommodated in the recesses A, and are welded to the disc B at N, and to the ribs L, and also to the outermost parts of the ribs. The outer segments of the rods, as denoted by the dotted portion O, are removed, after the assembly has been welded and dovetail grooves P are cut longitudinally in the rods, longitudinal slots, denoted by dotted lines Q, being cut in the rods before they are welded in position. The laminæ forming the magnetic core of the rotor are assembled so as to encircle the array of rods M in the disc B and are retained and prevented from rotation relatively to the spider by projections of dovetail shape which are received in the dovetail slots P provided in the rods M. The end faces of the bars M have circumferential slots R extending to the outer peripheries to accommodate end plates for retaining the laminæ in position against axial movement, and alternate rods M are drilled and tapped as shown at S at each end, to accommodate bolts for securing the end plates. Certain of the rods M, which are spaced at regular intervals, are drilled at both ends, as shown at T, to accommodate dowels to ensure the correct location of the end plates.—*September 28th*, 1933.

FURNACES.

399,409. March 23rd, 1933.—Regenerators, *H. A. Gill*, 51, *Chancery-lane, London, W.C.2.*

The inventors explain that with the usual arrangement of regenerator there is a tendency for the hot gases, whose heat is to be utilised, to rise into the upper part of the regenerator, while the cold air, which is to be heated, tends to flow through the lower parts. As a consequence they definitely guide the gases, by the baffle A, or some such means, so that the hot gases going into the top of the regenerator must go on to the lower part of the second pass, and those going into the lower part of the first pass go on to the upper part of the second.—*October 5th*, 1933.

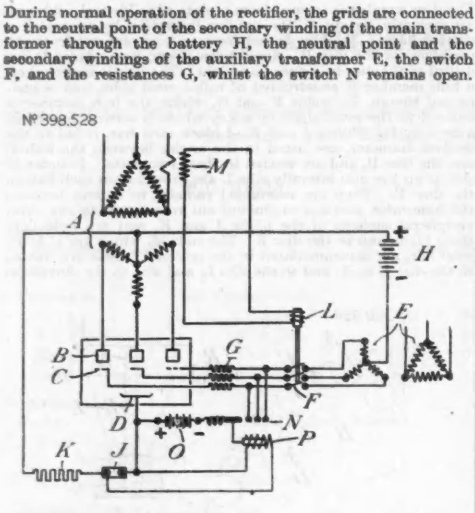
MISCELLANEOUS.

398,528. March 8th, 1932.—Mercury Vapour Rectifiers, Aktiengesellschaft Brown, Boveri et Cie., of Baden, Switzerland.

This specification describes a system of grid control for mercury arc rectifiers, in which the grid is maintained more positive than its associated anode during the active period, and more negative than the anode during its normal inactive period, whilst in the case of an overload or a back ignition the normal charging of the grid with respect to the anode is suspended. On the occurrence of back-arcing, the grid may also be connected to a source of voltage which is negative with respect to the cathode. The main transformer A feeds the anodes B of the rectifier. Grids C are interposed between the anodes and the cathode D, and are fed during normal operation by the auxiliary transformer E through a switch F and resistances G. The neutral point of the secondary of this transformer is connected as shown to the neutral point of the secondary of the main transformer through a battery H. The cathode D is connected through the shunt J and the load K to the neutral point of the secondary of the main transformer. The switch F is closed during normal operation of the rectifier and is arranged to break the connection of the grids to the transformer E when necessary by means of the solenoid L, which is energised by the current transformer M, associated with the primary of the main transformer A. The leads between the grids C and the switch F are connected by way of a switch N and a battery O to the cathode. The switch N is normally open, but may be closed by the solenoid P when the latter is energised by a predetermined current through the shunt J.

During normal operation of the rectifier, the grids are connected to the neutral point of the secondary winding of the main transformer through the battery H, the neutral point and the secondary windings of the auxiliary transformer E, the switch F, and the resistances G, whilst the switch N remains open.

Nº 398.528

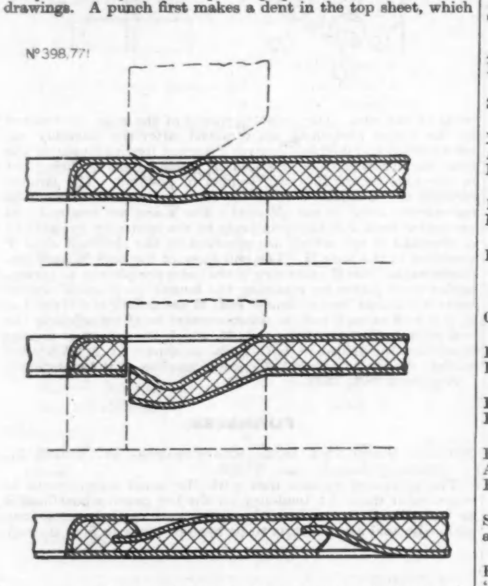


When a back-fire occurs the solenoid operates and opens the switch F and isolates the grids from the transformer E. The back-fire may also cause the solenoid P to close the switch N and impose a voltage upon the grids which is negative with respect to the cathode D by the voltage of the battery O.—*September 8th*, 1933.

398,771. April 29th, 1933.—COMPOSITE GASKETS, C. Kaiser, Schillerstrasse 47, Heilbronn am Neckar, Germany.

In order to key together the several thicknesses of a composite gasket, such as one made of asbestos and copper sheets, the pack is subjected to a pressing operation, as shown in the drawings. A punch first makes a dent in the top sheet, which is consequently stretched. Further descent of the punch sheers off first the top sheet, and then the bottom sheet, but on one side only. The pack is then flattened out again in another press, so that the elongated end of the stretched dent is tucked into the asbestos. The process is repeated on the opposite side. —*September 21st*, 1933.

Nº 398.771



Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

TO-DAY.

FINSBURY TECHNICAL COLLEGE OLD STUDENTS' ASSOC.—At Inst. of Chemistry. Sixteenth Streatfield Memorial Lecture, "Beer," Mr. H. F. E. Hulton. 8 p.m.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. "Heat Liberation and Transmission in Large Steam-generating Plants," Messrs. E. W. Robey and W. F. Harlow. 6 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Recording Sound for Motion Pictures," Mr. W. Harris. 7.30 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS.—At Mining Inst., Newcastle-upon-Tyne. "Tramp Ship Design: An Owner's Views and Requirements," Mr. W. L. Runciman. 6 p.m.

OVERHEAD LINES ASSOCIATION.—At Georgian Restaurant, Harrods, Ltd. Annual conversazione.

PHYSICAL SOC.—At Imperial College of Science and Technology, S.W.7. Editing Committee meeting, 3.30 p.m.; Council meeting, 4 p.m. Presidential address, "The Measurement of Magnetic Field Distortion," Professor A. O. Rankine. 5 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. Discourse by Sir Herbert Baker. 9 p.m.

WEST OF SCOTLAND IRON AND STEEL INST.—At Royal Technical College, Glasgow. Council meeting, 6.45 p.m. "Fusion Welding of High-pressure Vessels Combined with X-ray Examination," Mr. R. Rankine Lynn. 7.15 p.m.

TO-DAY AND SATURDAY, NOVEMBER 18TH.

PUBLIC WORKS CONGRESS AND EXHIBITION.—Royal Agricultural Hall, Islington, N.1. Daily. (For programme see page 365).

SATURDAY, NOVEMBER 18TH.

INST. OF ELECTRICAL ENGINEERS: N. MIDLAND STUDENTS.—Visit to works of P. Garnett and Sons, Ltd., papermakers, Otley. 3 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. "The Course and Causes of the World Depression," Mr. L. C. Robbins. 3 p.m.

MONDAY, NOVEMBER 20TH.

INST. OF ELECTRICAL ENGINEERS: S. MIDLAND.—At James Watt Memorial Inst., Birmingham. "The Lower Voltage Sections of the British Grid System," Mr. C. W. Marshall. 7 p.m.

INST. OF ELECTRICAL ENGINEERS: WESTERN CENTRE.—At Cheltenham. Discussion on "Gale and Storm Damage." Opener, Mr. W. D. Tuck.

INST. OF MECHANICAL ENGINEERS: GRADUATES.—Storey's-gate, S.W.1. "Oil-fired Furnaces," Mr. R. H. B. Forster. 6.45 p.m

ROYAL SOC. OF ARTS.—John-street, Adelphi, W.C.2. Cantor Lecture, "Colour Block Prints," Lecture I., Mr. Hesketh Hubbard. 8 p.m.

TUESDAY, NOVEMBER 21ST.

INST. OF AUTOMOBILE ENGINEERS.—At Victoria Hotel, Wolverhampton. "The Correlation of Metallurgical and Economic Problems in the Selection of Automobile Engineering Materials," Mr. L. B. Hunt. 7.30 p.m.

INST. OF CIVIL ENGINEERS.—Great George-street, S.W.1. Discussion, "Impact of Wheels on Roads," Messrs. F. Aughtie, R. G. C. Batson, and A. F. C. Brown. 6 p.m.

INST. OF ELECTRICAL ENGINEERS: S. MIDLAND STUDENTS.—James Watt Memorial Inst., Birmingham. "An Electric Totalisator," Mr. E. Plumley. 7 p.m. In connection with this paper, Perry Barr Stadium will be visited on Thursday, November 23rd, at 7.30 p.m.

REINFORCED CONCRETE ASSOCIATION.—20, Dartmouth-street, S.W.1. "The Decorative Treatment of Concrete Surfaces," Mr. Maxwell Ayrton. 7 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. "Liquid Crystals," Sir William Bragg, F.R.S. 5.15 p.m.

SHEFFIELD METALLURGICAL ASSOC. — 198, West-street, Sheffield. Discussion, "Rolling Faults in Steel," Mr. G. M. Brown. 7.30 p.m.

WEDNESDAY, NOVEMBER 22ND.

BELFAST ASSOCIATION OF ENGINEERS.—Central Hall, Municipal College of Technology, Belfast. (Joint meeting with the Inst. of Mechanical Engineers: London.) Thomas Lowe Gray Lecture, "Eight Years Salvage Work at Scapa Flow," Mr. E. F. Cox. 7.30 p.m.

INST. OF AUTOMOBILE ENGINEERS.—At Engineers' Club, Albert-square, Manchester. "Transmission Principles," Mr. L. H. Pomeroy. 7 p.m.

INST. OF CIVIL ENGINEERS: STUDENTS.—Great George-street, S.W.1. Address by Mr. A. S. West. 6.30 p.m.

INST. OF ELECTRICAL ENGINEERS: WIRELESS SECTION MEETING.—Savoy-place, Victoria Embankment, W.C.2. Mr. A. Morris will open discussion, "The Interference of Electrical Plant with the Reception of Radio Broadcasting." 6 p.m.

INST. OF STRUCTURAL ENGINEERS: SCOTTISH BRANCH.—At 129, Bath-street, Glasgow. "Specification Problems," Mr. A. Leitch. 7.30 p.m.

ROYAL SOC. OF ARTS.—John-street, Adelphi, W.C.2. "The Radiographic Use of Radium," Dr. V. E. Pullin. 8 p.m.

THURSDAY, NOVEMBER 23RD.

ANNUAL CHEMICAL DINNER.—Wharncliffe Rooms, Hotel Great Central, Marylebone, N.W.1. Dinner, 7.30; dancing, 9.15 p.m.

BRITISH SCIENCE GUILD.—In Goldsmiths' Hall, Foster-lane, E.C.2. Norman Lockyer Lecture. "Empire Communication," Professor E. V. Appleton, F.R.S. 4.30 p.m.

INST. OF ELECTRICAL ENGINEERS.—Savoy-place, Victoria Embankment, W.C.2. "Recent Investigation on Telephone Interference," Messrs. W. G. Radley and S. Whitehead. 6 p.m.

INST. OF LOCOMOTIVE ENGINEERS.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "The Roller Bearing as Applied to Locomotives and Rolling Stock on Railways," Mr. P. A. Hyde. 6 p.m.

INST. OF MARINE ENGINEERS: JUNIOR SECTION.—At L.C.C. School of Engineering, Poplar, E. Lantern lecture, "Thrust and Journal Bearings," Mr. J. Hamilton Gibson. 7 p.m.

INST. OF MECHANICAL ENGINEERS: N. WESTERN BRANCH.—Engineers' Club, Manchester. Thomas Hawksley Lecture, "Kinematic Design in Engineering," Prof. A. F. C. Pollard. 7.15 p.m.

INST. OF MECHANICAL ENGINEERS: YORKSHIRE.—At Queen's Hotel, Leeds. Chairman's address, Mr. A. N. Gledhill. 7.30 p.m.

INST. OF STRUCTURAL ENGINEERS.—10, Upper Belgrave-street, S.W.1. "Building Regulations," Mr. C. Roland Woods. 6.30 p.m.

SHEFFIELD METALLURGICAL ASSOC. — 198, West-street, Sheffield. "Applications of X-rays to Metallurgical Investigations," Mr. J. W. Rodgers. 7.30 p.m.

UNIVERSITY OF LONDON.—King's College, Strand, W.C.2. Department of Mechanical Engineering. "Injection and Combustion in High-speed Oil Engines: vi., Designs of Combustion Chambers—Actual Performance—Trends of Development," Dr. S. J. Davies. 5.30 p.m.

FRIDAY, NOVEMBER 24TH.

INST. OF STRUCTURAL ENGINEERS: MIDLAND COUNTIES.—At James Watt Memorial Inst., Birmingham. "Designing for Welding," Mr. C. Helsby. 7 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Refrigerating Machines and their Applications," Mr. W. S. Douglas. 7.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. Discourse, "Liquid Crystals," Sir William Bragg, F.R.S. 9 p.m.

SATURDAY, NOVEMBER 25TH.

INST. OF CIVIL ENGINEERS.—Students' visit to Erith works of Callender's Cable and Construction Company, Ltd.

MONDAY, NOVEMBER 27TH.

ENGINEERS' GERMAN CIRCLE.—At Holborn Restaurant, W.C.1. Dinner and dance. Reception, 7.30 p.m.

TUESDAY, NOVEMBER 28TH.

INST. OF ELECTRICAL ENGINEERS: SCOTTISH CENTRE.—Grosvenor Restaurant, Gordon-street, Glasgow, C.2. Annual dinner and ladies' evening. 6.30 p.m. for 7 p.m.

WEDNESDAY, NOVEMBER 29TH.

INST. OF MECHANICAL ENGINEERS: N. WESTERN GRADUATES.—Engineers' Club, Manchester. "Tidal Power Schemes," Mr. J. L. Morden. 7.15 p.m.

THURSDAY, NOVEMBER 30TH.

INST. OF CIVIL ENGINEERS: YORKSHIRE ASSOC.—Hotel Metropole, Leeds. Short paper by students for discussion. "Tramway Reconstruction," Mr. C. R. Warman: "An Economic Aspect of Reinforced Concrete," Mr. E. A. Dyer. 7.30 p.m.

INST. OF LOCOMOTIVE ENGINEERS.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. Informal meeting. Mr. O. Bulleid will open discussion on "The Most Suitable Form of Traction for Main Line Railway Operation." 6 p.m.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—In James Watt Memorial Inst., Birmingham. "Symposium on Defects in Cold Working," arranged by Mr. A. L. Molineaux. 7 p.m.

FRIDAY, DECEMBER 1ST.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Thomas Lowe Gray Lecture, "High-speed Diesel Engines for Marine Service," Mr. H. R. Ricardo, F.R.S. 6 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Dairy Machinery and Plant," Mr. W. Chopping. 7.30 p.m.

SATURDAY, DECEMBER 2ND.

STEPHENSON LOCOMOTIVE SOC. (MIDLANDS).—At Crumpsall Library, Manchester. "The Liverpool Overhead Railway." 6.30 p.m.

TUESDAY, DECEMBER 5TH.

CHADWICK PUBLIC LECTURES.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Rural Sanitation," Mr. J. H. Coste. 8 p.m.

WEDNESDAY, DECEMBER 6TH.

INST. OF MECHANICAL ENGINEERS: N. WESTERN BRANCH.—(Joint meeting with the Liverpool Engineering Soc., Liverpool.) Thomas Lowe Gray Lecture, "High-speed Diesel Engines for Marine Service," Mr. H. R. Ricardo, F.R.S. 7.15 p.m.

THURSDAY, DECEMBER 7TH.

INST. OF MECHANICAL ENGINEERS: N. WESTERN.—Engineers' Club, Manchester. "Factors Affecting the Grip of Force, Shrink and Expansion Fits," Mr. R. Russell. 7.15 p.m.

INST. OF STRUCTURAL ENGINEERS: YORKSHIRE BRANCH.—Hotel Metropole, Leeds. "Properties of Concrete—A Summary of Present-day Information," Mr. J. Singleton-Green. 7 p.m.

FRIDAY, DECEMBER 8TH.

INST. OF ELECTRICAL ENGINEERS: S. MIDLAND STUDENTS.—Boots' Café, Colmore-row, Birmingham. Annual dance.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Informal meeting. Discussion, introduced by Mr. A. Perry-Keene, "Shop Organisation." 7 p.m.

RAILWAY CLUB.—57, Fetter-lane, E.C.4. "Signalling, Remote Control," Mr. Edward Wallis. 7.30 p.m.

SATURDAY, DECEMBER 9TH.

INST. OF MARINE ENGINEERS.—The Minories, E.C.3. Junior Section's social and dance. 7.30 p.m. to 11.15 p.m.

STEPHENSON LOCOMOTIVE SOC.—Headquarters, King's Cross Station, N.1. Annual general meeting, 3 p.m., Midland Grand Hotel, St. Pancras, N.1. Annual dinner, 6.30 p.m.

MONDAY, DECEMBER 11TH.

ENGINEERS' GERMAN CIRCLE.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Verbesserung von Schiffsgrundrissen (Improvement of Ships' Sections)," Herr Dr.-Ingenieur Eberhard Westphal, of the Technische Hochschule, Danzig. The lecture will be followed by a technical discussion in German. 5.30 for 6 p.m.

TUESDAY, DECEMBER 12TH.

INST. OF AUTOMOBILE ENGINEERS.—At Merchant Venturers' Technical College, Bristol. "Transmission Principles," Mr. L. H. Pomeroy. 7 p.m.

INST. OF MARINE ENGINEERS.—The Minories, E.C.3. "Notes on the Manufacture of Piston Rings and their Relation to Liner Wear," Mr. H. J. Young. 6 p.m.

INST. OF MECHANICAL ENGINEERS: N. WESTERN BRANCH, GRADUATES.—Engineers' Club, Manchester. "Bauer Wach Exhaust Steam Turbines," Mr. E. Crossley. 7.15 p.m.

THURSDAY, DECEMBER 14TH.

INST. OF MARINE ENGINEERS: JUNIOR SECTION.—The Minories, E.C.3. Film display, I., "The River Tyne," II., "The World of Machinery at the Leipzig Engineering Fiar." 7 p.m.

FRIDAY, DECEMBER 15TH.

INST. OF CHEMISTRY.—30, Russell-square, W.C.1. Fifth S. M. Gluckstein Memorial Lecture. "The Chemist as a Directing Force in Industry," Dr. Herbert Levinstein. 8 p.m.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN CENTRE.—Grand Assembly Rooms, Barras Bridge, Newcastle-upon-Tyne. Annual dinner and dance. 7 for 7.30 p.m.

RAILWAY CLUB.—Broad-street Station Restaurant, E.C. Annual dinner.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

RICHARD DUNSTON, Ltd., of Thorne, near Doncaster, has received an order for the construction of a steel canal barge. An order has also been received by the associated company, Henry Scarr, Ltd., of Hessle, near Hull, for a motor barge.

THE HYDRAULIC ENGINEERING COMPANY, Ltd., Chester, has received from Imperial Chemical Industries, Ltd., Billingham, an order for four 395 horse-power, high-pressure, hydraulic pumps in connection with the scheme for the production of petrol by the hydrogenation of coal.

JOHN M. HENDERSON AND CO., Ltd., King's Works, Aberdeen, have recently received contracts for two 5-ton electrically driven fixed aerial cableways for the Crown Agents for the Colonies for Hong Kong, and a 15-ton level luffing crane for the new fish docks for Grimsby Corporation.

DAVEY, PAXMAN AND CO. (Colchester), Ltd., have received an order for a five-cylinder heavy-duty oil engine of 500 H.P. for a dredger being built by W. Simons and Co., Ltd., of Renfrew. They have also in hand four eight-cylinder engines for driving paddle boats being constructed by Denny Brothers, Ltd., for the Queensferry service, and, amongst others, a 200 B.H.P. six-cylinder steel-framed engine for a shunting locomotive being made by the Hunslet Engine Company, Ltd., for the L.M. and S. Railway.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

BABCOCK AND WILCOX, Ltd., announce that Mr. Christopher S. Davy, chief engineer, has been appointed to a seat on the board.

WILLIAM GEIPEL, Ltd., Vulcan Works, 156–170, Bermondsey-street, London, S.E.1, have been appointed sole agents in this country for "Ringsdorff" arc lamp carbons.

MR. G. W. PRESTON, A.M.I.E.E., has been appointed electrical engineer to the recently formed Copper Development Association of Thames House, Millbank, S.W.1.

PETER STUBS, Ltd., Warrington, has appointed Mr. Len. B. Booth, of 29, Much Park-street, Coventry, as representative in Coventry for the sale of the firm's high-quality steels.

MR. W. A. SMITH, inventor of the "Pneuconex" grit-catching and pneumatic conveying installations, has now arranged licences with Compagnie des Transporteurs Simplex, 48, Boulevard des Batignolles, Paris, France, for use in France, Belgium, Spain, Italy, and Portugal; and from Ardeltwerke G.m.b.H., Postschliessfach 86/87, Eberswalde, Germany, for use in Germany, Russia, Holland, Turkey, and Central European countries.

A Seven-Day Journal

Science and the Nation.

Among the activities of the Association of Scientific Workers, mentioned in the newly published report of the Executive Committee, is the recent formation of the Parliamentary Science Committee referred to in our Journal note of November 3rd. Another activity is the preparation of a memorandum on the question of the inter-relation and unification of national transport. This memorandum deals with the possible construction of three ship canals across Great Britain, the reconstruction of certain of our canals now derelict, and the drainage of a very considerable area of ground in England. In this connection it may be recalled that Mr. Walton Maughan, of Holmfirth, one of the members of the Association, has studied for many years the question of cross-country ship canals, and embodied his proposals in a paper read at the Leicester meeting of the British Association. A synopsis of that paper appeared in our issue of September 22nd. During the period reviewed by the Committee's report, the Association has continued its active support of the campaign for Basic English in science and the internationalisation of scientific terms. The Committee, in conclusion, draws attention to the resolution passed at the British Association Leicester meeting urging the consideration of means by which the British Association may assist towards a better adjustment between the advances of science and progress, and the suggestion of its President, Sir Gowland Hopkins, that it may be for the scientist rather than the politician to solve the problems with which we are faced.

Coal-Oil Developments.

On Wednesday, November 15th, it was announced that a contract had been arranged between the London, Midland and Scottish Railway Company and Low Temperature Carbonisation, Ltd., for a bulk supply of oil fuel made from British coal. The first contract is for 1500 tons of oil, and is, we understand, only one of a number of similar contracts which have been arranged during the past two months by a number of important industrial firms. Since the imposition by the Government of the tax of 1d. per gallon on foreign fuel oil in April last, there has been a steady increase in the volume of the trade done by the British oil fuel industry, which, we are given to understand, is now ten times greater than it was before the duty was imposed. According to Colonel W. A. Bristow, the managing director of Low Temperature Carbonisation, Ltd., there is now an assured and profitable market for all the oil which can be produced from British coal for many years to come. Already over 100,000 tons of fuel oil and petrol have been made by the "Coalite" process, and the varied finished and refined fractions are now being marketed and are giving, it is claimed, great satisfaction. Large quantities of coal oil are now being employed in Sheffield for furnaces engaged in the production of stampings and drop forgings, while the use of such oil in specially designed glass furnaces is rapidly increasing. Arrangements for a considerable increase in the products of low-temperature carbonisation are now being concluded.

The Port of Richborough.

The announcement is made that Pearson and Dorman Long, Ltd., who are the owners of the port of Richborough, have agreed to the transference of the lease of the train ferry terminus at Richborough, formerly granted to Great Eastern Train Ferries, Ltd., to a French company for a term of years. It is expected that a new Anglo-French ferry service between Richborough and in all probability Dunkirk will be inaugurated by the Compagnie Française des Ferry Boats during the summer of 1934. The traffic will consist mainly of fresh fruit and flowers from Spain, the South of France, and Italy, which is to a large extent in the hands of the French company. From the port of Richborough the wagons will go direct, *viâ* Minster Junction, to the Bricklayers' Arms Goods Station of the Southern Railway Company, where the produce will be loaded direct into motor lorries for distribution to the various markets. The new service will be additional to that between Dover and Dunkirk operated by the Southern Railway Company.

Costing Distribution.

In an address on "Costing Distribution," which was given at Sheffield on Wednesday, November 15th, before the Sheffield Branch of the Institute of Cost and Works Accountants, Major L. Urwick, the director of the International Management Institute at Geneva, emphasised the fact that manufacturers had not put the same thought into the problems of distribution and consumption which had been devoted to questions of production. Definite steps, he thought, were needed to restore economic equilibrium, and all those steps demanded the technique of costing. The usefulness of a costing system, Major Urwick contended, depended very largely on how the information so accumulated was applied. There was no use in spending money on a costing system if the results so obtained were not acted upon in fixing selling prices. In some cases of rationalisation, companies had had an efficient costing system, but they had neglected to be guided by the figures presented to them. In many instances a great idea had been hampered by inadequate application. The economic depression which had fallen upon the world was, he suggested, not the normal sickly depression which would yield naturally in due course. It was almost a complete breakdown of the world economic machinery, which would be followed by a deeper depression unless steps were taken to put the machinery in order. Any such steps would demand application of the technique of costing and a careful study of the problems of distribution.

Thames Floods.

A Departmental Committee on Thames Flood Prevention, under Sir William Hart, was appointed in the spring of 1931, but its deliberations were suspended owing to the financial crisis, and it did not resume its sittings until just a year ago. It has just issued its report. Its terms of reference were: "To consider the present organisation for the prevention of damage by floods in the tidal portion of the Thames, and to make recommendations as to the further measures, if any, that may be necessary, as to the authority or authorities to which the duty of carrying out any such measures should be entrusted, and as to the basis on which the cost should be distributed." It now proposes that a joint committee, to decide for the whole of the tidal basin of the Thames what works of flood defence are necessary, be set up. This committee would consist of not more than fifteen members:—London County Council three representatives; the County Councils of Essex, Kent, Middlesex, and Surrey each one member; the County Borough Councils of East Ham, West Ham, and Southend jointly represented by two members; the four Catchment Boards of the rivers Lee, Medway, and Roding jointly represented by two members; the Thames Conservancy with one member, and the Port of London Authority with three members. This committee would co-ordinate the work of the existing authorities, taking into consideration such technical questions as the effect on the area of surges from the North Sea and of the land subsidence which has occurred. The execution of approved schemes prepared by it would be placed in the hands of the catchment boards and the county and county borough councils. It would have control over the whole tidal area, including the tidal length of tributaries, and would undertake a survey with a view to the preparation of proposals for such works as it might consider necessary. The distribution of the cost of flood prevention works is discussed in the report, which contemplates that the cost of some works may have to be apportioned between authorities by the joint committee, but that normally the cost of works required in an area will fall on that area.

Oil Pollution.

On Monday last the Board of Trade issued a White Paper entitled "Reports as to the Extent of Oil Pollution Round the Coast," which was prepared as the result of an assertion made in the House of Lords in May last that the evil was increasing. As a matter of fact, the Board finds that there is some diminution in the oil pollution of navigable waters round the coast, but from Kent to Dorset and in the Bristol Channel it is still severe. The information summarised in the Report was secured by means of a questionnaire sent to 134 local authorities, harbour authorities, dockyards, ports, &c., and to societies interested in the preservation of bird and fish life. Recent inquiries instituted by the Board of Trade, and embracing 1100 vessels belonging to fifty-three British shipping companies, indicate that approximately 50 per cent. of the vessels are coal burning, and do not use oil fuel or carry oil as cargo, and, therefore, separators are not required. Of the oil-burning and oil-carrying vessels reported upon, 132, or 24 per cent., were fitted with separators. The fitting of separators on board ship would not, the Board adds, provide a remedy in respect of oil discharged (1) by inadvertent discharge overboard owing to misuse of control valves; (2) through stranding; (3) through collision; and (4) possibly from vessels lost during the war years which may only now be breaking up and discharging quantities of oil.

Testing Compressed Air Cylinders.

At a meeting of the Diesel Engine Users Association on November 15th, the procedure to be adopted—if it was considered desirable to adopt a uniform procedure—for the examination and testing of air cylinders was discussed. The joint hon. secretary explained that the object of the Committee in holding the discussion was not to alarm members or because there was a considerable danger of accidents, but in order to pool experience, and, if thought desirable, to lay down broad rules for procedure. Members abroad had recently written asking for guidance about the proper maintenance routine for air cylinders, and, as the question had not been discussed by the Association since 1922, when a fire at a generating station caused a considerable amount of damage by the bursting of compressed air cylinders, a letter had been circulated to members on October 23rd last inviting them to reply to a number of questions. The replies to these questions showed what a wide diversity there was in procedure. It appeared that periodical examinations were carried out at intervals varying from three months to five years. Some members examined cylinders at irregular intervals, and some not at all. Periodical tests were carried out at intervals of from six months to five years, while 41 per cent. of the replies reported that tests were carried out at irregular intervals. When water pressure tests were applied, practice varied between a test at working pressure and twice the working pressure; 42 per cent. of members who replied said that the test and the test pressure were left to the insurance company. Only 13 per cent. reported that an internal inspection was made. Several members informed the Committee that they coated the internal surfaces of their cylinders with shellac and spirit, or a bituminous composition. In view of these replies, and of the fact that recently the British Standards Institution had drawn up specifications for air cylinders, it appeared to be desirable to draft suggestions for maintenance. The Admiralty regulations for the testing and examination were dead. After discussion it was proposed by Mr. J. G. Griffin, and seconded by Engineer Rear-Admiral Harrison, that the Committee be requested to consider the questions raised during the discussion, and if it considered action necessary to appoint a sub-committee to draw up general rules for the guidance of members.

Industrial Areas.

The remarkable fact that more than half the insured population of the United Kingdom is now to be found in the London, South-Eastern, South-Western, and Midland areas is revealed by the latest inquiries of the Ministry of Labour. In six years the total number in the South and Midlands has increased by 754,000, and in the North by no more than 312,000. The depression in the heavy engineering industries and coal mining has no doubt had some effect upon the figures. Between July, 1932, and July, 1933, the increase in the London area amounted to 33,000, in the South-East to 16,000, in the South-West to 5000, in the Midlands to 18,000, in Scotland to 6000, and in Wales to 2000. The total number of insured persons in July last was 12,883,000, and showed an increase of 75,000 in twelve months. Out of the total, 8,829,000 were men and 3,137,300 women. Figures show that the movement of men out of the depressed trades continued, particularly in general and marine engineering, shipbuilding, and ship-repairing, the displaced men entering a large variety of other trades. It is of interest to note that employment in mining and quarrying decreased by nearly 14 per cent. in the ten years preceding 1923, whilst in transport, communications, storage, and distribution it augmented in the same period by no less than 42·6 per cent. Since in the same decade the number of insured persons in the manufacturing industries rose by no more than 5·3 per cent., we have a clear indication of the importance which distribution now takes in the economy of the nation.

A Compressed Gas Filling Station.

An event of considerable interest to the road transport industry took place at the works of the Chesterfield Tube Company, Ltd., at Chesterfield, on Wednesday, November 15th, when the first public filling station for gas-driven vehicles was formally opened by Mr. Ernest Brown, the Parliamentary Secretary for Mines. Mr. Brown was introduced by Mr. W. A. Woodeson, the chairman of the company, who briefly referred to the economies which were to be gained by running on compressed gas. The plant comprises the four-stage electrically driven Bryan Donkin gas compressor which was exhibited at the last British Industries Fair at Birmingham. It supplies compressed gas of about 480 B.Th.U. calorific value to three storage cylinders at a rate of about 100 cubic feet per minute and at a pressure of 5000 lb. per square inch. Suitable pressure governing devices for charging the gas cylinders of the transport vehicles are provided, and it was demonstrated that refilling could be quickly and simply accomplished. In the course of his speech at the luncheon which followed the opening ceremony, Mr. Ernest Brown paid a tribute to the pioneer research work which had been done by the Chesterfield Tube Company, Ltd., and Vickers-Armstrongs, Ltd., in the production of light high-pressure steel vessels for gas storage. He expressed the hope that the station he had opened would be the first of a whole chain of filling stations covering the country and serving industry, and suggested that colliery companies and allied industries should convert a proportion of their vehicles to utilise compressed gas instead of petrol fuel, and thus enable further improvements to be made in compressed gas distribution. During the day many of the visitors, of which there were about 200 present, had an opportunity of witnessing for themselves the manufacture and testing of high-pressure steel cylinders and tubes for industrial and marine engineering uses.

Recent Hydro-Electric Power Plants in Sweden.

No. III.

(Continued from page 484, November 17th.)

THE KRANGEDE WORKS.

THE co-ordination of electric power resources, apart from national or State organisation, has nowhere been carried out more effectively than in Sweden. A well-known instance of such co-operation is the Bergslagen Co-operative Power Corporation formed for the purpose of exploitation and distribution of electric power in that part of Central Sweden called Bergslagen. Another example of co-operation between otherwise independent industrial and public utility interests for the joint exploitation of a very large source of power is the Krangede scheme, the object of which is to profit both from the technical and economic advantages, which can only be attained by large-scale power production, without sacrificing independence in respect of power supply. The difference between this co-operative enterprise and other large power undertakings is chiefly a matter of organisation.

FIG. 23—PLAN VIEW OF GENERATOR HALL

It was foreseen more than twenty years ago that the power resources of Bergslagen, as well as of the adjacent industrial regions of Central Sweden, would be insufficient in the near future. With the development of long-distance transmission of electric energy the idea of making use of a remote supply of water power became more than a possibility. On the initiative of Mr. Sven Lübeck, now the Governor of the Province of Gävleborg, five ironworks in Central Sweden, in 1916, purchased the rights in the Krangede Waterfalls, one of the biggest in Sweden. The falls are in the Indal River in the Province of Jämtland, North Sweden, about 350 kiloms. north of the prospective load centre. The purchasers of the power rights were afterwards joined by the Bergslagen Power Company and at the present time the partners in the undertaking are three iron and steel works—Sandviken, Fagersta, and Hofors—the Korsnäs Saw Mills, the Bergslagen Power Company, and the City of Stockholm. The Krangede enterprise is organised in the form of a joint stock company, the individual shareholders owning an approximately equal number of shares. The power will be allotted to the shareholders in proportion to the shares owned and will be paid for at a price corresponding to the company's own production cost. It is of special interest to note that the production cost is not to be allocated in proportion to the maximum demand only, but that a certain, although very small, kWh charge is to be paid corresponding to the value of energy for steam generation and other similar power supplies. This charge is to vary with the cost of coal, but will be not less than 0·2 ore per kWh (1 ore=approximately ⅛d.), with 100 per cent. rise during low-water periods. The remainder of the energy charge is in proportion to the demand. Any energy not required by a shareholder for his own business will be offered to the other shareholders in the company before any sale of such energy to outside parties is arranged. Apart from the general power agreement between the shareholders, separate and special power contracts may be made between the company and its individual shareholders. Such a contract has already been concluded with the City of Stockholm, which, in addition to its full share of power, has subscribed for 4000 kW at the company's cost price. The contract also contains stipulations to the effect that any surplus energy from the Krangede plant shall first be placed at the disposal of the city and the latter shall supply the company with stand-by power from its large steam power plants.

FIG. 24—HALF-SECTION THROUGH TURBINE

The construction of the Krangede works was begun in 1931 and the first section of the plant is expected to be completed in 1936. This section comprises two vertical turbine units of 35,000 kW each, and the plant, when fully developed, will consist of six such units or a total of 210,000 kW. A transmission line for a voltage of 220 kV is to be constructed from Krangede to Horndal in Bergslagen over a distance of 340 kiloms.—see plan, Fig. 26. At Horndal a substation for 200/70 kV is to be erected from which a distributing system for 70 kV is to be fed. Stockholm's share is to be drawn at 200 kV at Horndal, and by a line for the same voltage, owned by the city, transmitted to the capital, which is 450 kiloms. from Krangede in a direct line.

THE POWER PLANT.

A dam, 220 m. in length and 18 m. in height, is now being constructed across the river at the head of the Krangede Falls. The dam is of a modified gravity type, which we shall describe hereunder. It is to be provided with four large gates, viz., three Taintor gates and one sector gate, each 20 m. in width and about 7 m. in height. The Taintor gate openings are intended for the discharge of flood water, whereas the sector gate has the additional purpose of passing timber logs floated down the river. The sector gate is of the hydraulically counterbalanced type, which has been successfully used in several hydro-electric power plants in Sweden and which has previously been described in English technical journals. The river will be dammed to the level of Lake Gesunden, which, covering an area of about 30 square kilometres, will serve as a reservoir for water regulating purposes. The geological formation at the Krangede Falls consists chiefly of grey and reddish granites and syenites, which are closely interconnected and therefore may be termed granite-syenite. This is in some places intersected by a dark basic rock, diabase. At the site of the dam the rock is bare and is nowhere overlain by soil, except to a depth of a few feet, in any part of the river bank where the works connected with the dam are being constructed. From the intake, designed as an extension of the dam on the left bank of the river, the water will be passed through vertical shafts, excavated in the rock, to the turbines, which, together with the generators, will be installed in an underground machinery hall, likewise excavated in the rock. The floor of the turbine room is about 57 m. below the intended water level at the back of the dam and 47 m. below ground level. The first section of the works includes three separate intakes and penstock shafts; one set for each turbine, two of which will be installed at present.

DISCHARGE TUNNEL.

The water discharged from the two draft tubes of the turbines flows into a large tunnel, 1400 m. in length, driven through the rock to an exit on the left bank of the river below the rapids. This tunnel (Figs. 25 and 27), constructed entirely in rock, is 13·4 m. high and 11·0 m. wide, and has a cross-sectional area of about 116·0 square metres, larger than that of any discharge tunnel so far driven in rock. Its floor at the upper end is at level +137·0 m. or 67 m. below the dam water level. The level of the invert at the tunnel outlet is +135·5. Tunnelling was begun at the lower end near, but just inside, the river bank, which will be cut through when the tunnel works are completed. The rock excavated from the tunnel is run to a spoil bank extending along the

bank of the river below the outlet. The rock in which the tunnel has been driven is compact and hard. In only a few places has any timbering been necessary to support small areas of the roof. It is not proposed to line the tunnel, except in those few positions where loose rock is met with. As we have already indicated, this tunnel will serve for the discharge from three turbine sets, two of which will be installed in the first instance. When the fourth unit of the plant is constructed, the provision of a second tunnel will be necessary, which will ultimately serve for the discharge of the remaining three units. The maximum water discharge from the draft tubes of the first pair of turbines will be 140 cubic metres per second, and the corresponding mean velocity in the tunnel about 1·8 m. per second. An interesting feature of the tunnels is that the roof is elevated so that the tail water level will always be free. A special surge chamber is therefore not required in this case. Precautions are, of course, taken to safeguard the works, if, under certain exceptional conditions and by a sudden and great increase of load during exceptionally high tail water level, the tunnel should be filled and a heavy rise of pressure in the tunnel occur.

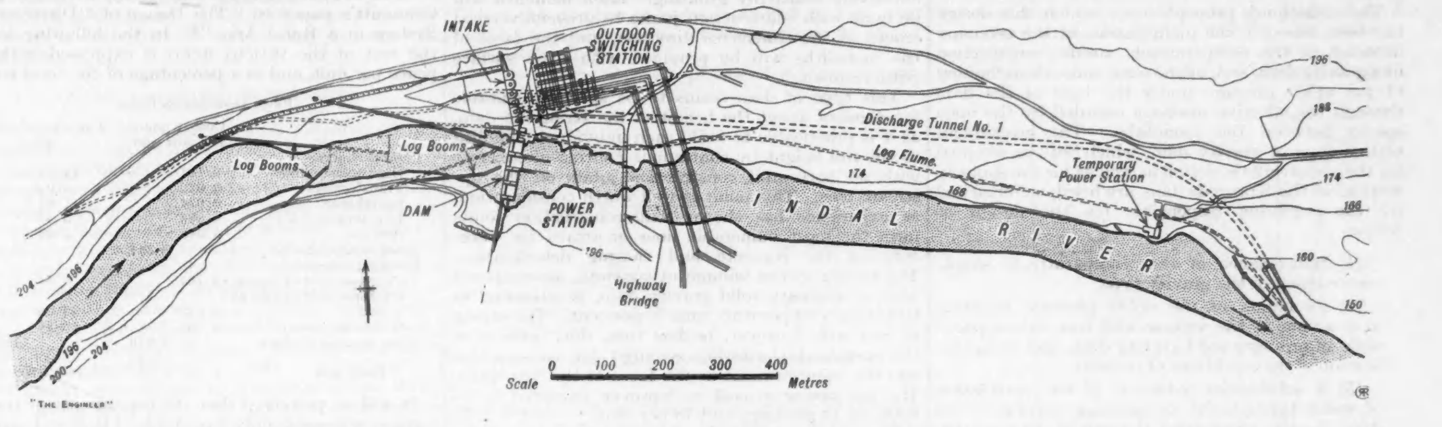

FIG. 27—DETAIL MAP SHOWING SITUATION OF DAM, POWER STATION AND DISCHARGE TUNNEL

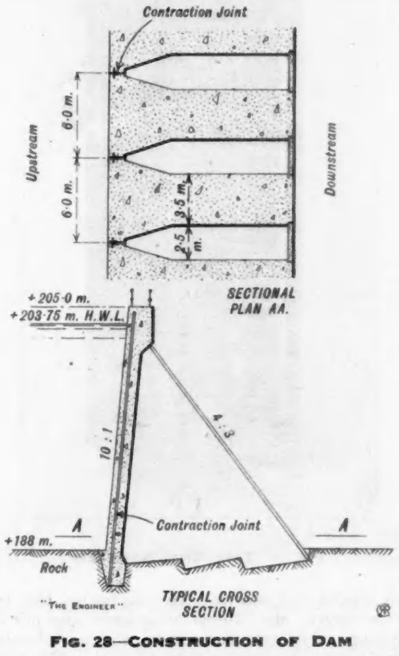

FIG. 28—CONSTRUCTION OF DAM

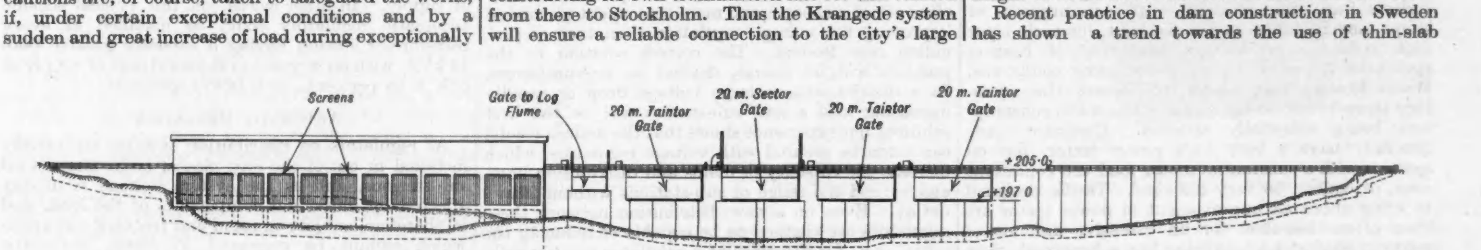

FIG. 29—GENERAL ELEVATION OF UPSTREAM FACE OF DAM

All drilling in the tunnel is done by compressed air. The rock *débris*, after blasting, is removed by an electrically driven Bucyrus excavator, and loaded into wagons, which are hauled by electric locomotives to the spoil dump. At the present time (August, 1933) about half the length of the tunnel has been opened out to the full section and the pilot heading has been driven through to the shafts at the power station.

POWER STATION.

The available gross head of water at the power station is about 60 m. The turbines (Figs. 23, 24, 25,) will be of the vertical shaft, single-runner Francis type, mounted in steel spiral casings; each will have a rating H.P. of 45,000. The normal water consumption of each turbine is to be 55 cubic metres per second at 57·7 m. head. Under these conditions the guaranteed maximum efficiency is 92 per cent. At 70 cubic metres per second discharge and the same head, the turbine will develop 47,400 H.P. The speed is 166·7 r.p.m., and the head will vary between 54 m. and 60·5 m. The runners are of cast steel and 3·5 m. diameter. The generators (Figs. 23 and 25), to be coupled direct to the turbines, are rated at 35,000 kVA, 10 kV, and 50 p/s. Each generator is to be connected to a three-phase self-cooled transformer for 35,000 kVA and 10/220 kV. The transformers and the high-tension switchgear are to be located out of doors (Fig. 27). The 10-kV bus-bars will feed the station service transformers and also a transformer for about 15,000 kVA at 10/70 kV, which will connect the station to the Hammarforsen hydro-electric power station, situated on the Indal River, some 18 kiloms. below Krangede. The generators and main transformers are being constructed by the Allmänna Svenska Elektriska Aktiebolaget (ASEA), Västeras, and the turbines by the Karlstads Mek. Verkstad, Kristinehamn.

TRANSMISSION LINES.

The 220-kV transmission line (see Fig. 26) between Krangede and Horndal, 340 kiloms., will be equipped with steel towers and copper conductors of 3 × 240 square millimetre section. At the Horndal substation two transformers, rated at 30,000 kVA and 200/70/10 kV, will be installed. The 10-kV winding is for the connection of reactors and synchronous condensers. The secondary lines are designed for 70 kV, and will be equipped with wooden poles and copper conductors, mostly of 3 × 70 and 3 × 95 square millimetre section. One of these lines will connect the system to the Lanforsen power station, jointly owned by the City of Stockholm and the Sandviken Ironworks, and also to the state power station at Alvkarleby. Another line will make connection with a projected 70-kV line, Västeras–Krylbo, in the State power distribution system.

The City of Stockholm will receive its share of power at 200-kV tension at the Horndal sub-station, constructing its own transmission line for this tension from there to Stockholm. Thus the Krangede system will ensure a reliable connection to the city's large steam power station at Värtan, which has an installed machinery capacity of some 100,000 kW.

THE DAM.

The foundations on the south side of the river have already been constructed, and a portion of the dam built (Fig. 27). On the north side the building of the intake and abutments is in progress. The overall length of the dam, including the intakes, is 350 m. (Figs. 27 and 29). A 5-tons aerial ropeway for constructional purposes spans the river at the dam site.

The most difficult portion of the dam construction —the building of that part which will cross the swift-flowing stream in the rapids—is to be carried out in accordance with the following programme, which is based on the experience gained in the construction of the cofferdam for the Hammarforsen station in 1926. During the low water period in the winter of 1933–34, the north half of the dam will be enclosed by a wooden cofferdam, and within this three piers (but not the overflow weir) will be concreted. The second stage of construction—covering the low water period in the winter of 1934–5—includes the building of a similar cofferdam enclosing the other half of the dam and the concreting of the dam structure within it with the exception of two 6 m. monoliths of the non-overflow portion. In the meantime, the river discharge will be through the openings left between the piers built in the 1933–34 season. The work to be carried out in the third stage of construction during the winter of 1935–6 includes the successive closing of the openings in the dam left for the discharge of the river flow, the concreting of these weir sections between the piers built in 1934, and the concreting of the two remaining monoliths of the non-overflow portion of the dam. The dam will have a maximum height of 18 m. above the rock in the river channel.

FIG. 30—DESIGN PARTICULARS OF DAM

Recent practice in dam construction in Sweden has shown a trend towards the use of thin-slab hollow dams of the buttressed type. At Krangede, however, the abundance of hard rock material available from the permanent works of the tunnel and shafts favoured mass concrete construction for the dam. The modified type of gravity dam which has been adopted is said to compare favourably with an ordinary solid gravity dam. A typical cross section and a part-sectional plan of the non-overflow portion of the dam on the right-hand side of the river, are shown in Fig. 28. The structure might be described as a laminar gravity dam, consisting of a number of vertical monoliths or piers, each 3·5 m. thick, and widening at the upstream end into a bulkhead 6·0 m. thick. The monoliths are placed at a distance apart of 6·0 m., centre to centre, thus leaving a free space of 2·5 m. width between the sections. The joints between the bulkheads serve as contraction joints, and each will be closed by a special sealing device.

The underlying principle upon which this design has been based is the maintenance of the economy inherent in the comparatively simple construction of a gravity dam, and, at the same time, the reduction of the uplift pressure under the base of the dam through the effective drainage afforded by the open spaces between the monoliths. The advantages of this type of gravity dam, which will be adopted for the non-overflow section as well as for the spillway sections of the Krangede dam, are briefly summarised by the engineers responsible for the design as follows:—

(1) Maintenance of the comparatively simple construction of the gravity type.

(2) Reduction of the uplift pressure resulting in a saving in the volume and cost as compared with an ordinary solid gravity dam, and in simplification of the conditions of stability.

(3) A substantial reduction of the percolation of water through the downstream portion of the dam, thereby eliminating the risk of deterioration in this part of the structure. Experience has shown that this is of importance in regard to the character of Swedish river waters.

(4) Facilitated inspection, and, if necessary, repair of the concrete.

(5) The prevention, as far as possible, of the formation of shrinkage and temperature cracks in the concrete by allowing each monolith to dilate independently of adjacent monoliths.

(6) Facilitated control of the generation and dissipation of the chemical heat in the concrete.

The uplift pressure assumed for the design is shown diagrammatically in Fig. 30. To prevent any undue uplift resulting from horizontal fissures or seams in the rock under the foundations, it is intended to drill wells into the rock from the open spaces between the monoliths and behind the cut-off trench, the rock under the trench having previously been effectively sealed by grouting. Each monolith will be built with construction joints to prevent vertical cracks in the transverse direction, and the faces of the monoliths will be provided with some surface reinforcement.

This type of dam seems to be specially suitable for dams of about the height of the Krangede dam, as it is practicable to build each individual monolith to the full height by continuous pouring of concrete with no horizontal construction joints on the upstream face. This point is well worth consideration, as experience has shown that construction joints form the most vulnerable lines of attack for water entering the concrete and causing deterioration. The saving in the volume of concrete, as compared with an ordinary solid gravity dam, is estimated to be between 20 per cent. and 30 per cent. The saving in cost will, however, be less than this, because of the increased shuttering required for construction and the reinforcement at the faces of the monoliths. The net saving in cost is, however, expected to be between 10 per cent. and 15 per cent.

The total cost of the first development of the Krangede power plant, with the intake and discharge tunnel completed for three units and the power station for two machinery units, including civil engineering works, machinery in the power station, and step-up transformers, is estimated to be 22 million Swedish kronor (about £1,120,000).

The consulting engineers for the Krangede works are Vattenbyggnadsbyran (VBB) of Stockholm.

(To be continued.)

A.C. Voltage Regulators.

No. I.

With the increasing use of electricity, and the consequent growth of load on supply systems, engineers in many parts are faced with the problem of maintaining correct pressure at consumers' terminals. Supply authorities, manufacturers, and users of electrical apparatus alike are adversely affected by imperfect voltage regulation, which, apart from the legal necessity of maintaining pressures within ±4 per cent., is undesirable. Consumers who do not get a properly controlled supply are very apt to become dissatisfied with results, and to blame manufacturers for the short life of lamps and apparatus, while supply undertakings may lose revenue. Lamps, heating elements, and wireless valves soon deteriorate if the pressure is excessive. Conversely, if it is low, lamps fail to give the requisite amount of light and heating elements the proper quantity of heat. Mains operated wireless sets may also work imperfectly if the voltage is incorrect, and the consumer who does not realise what is wrong may tell his friends not to purchase a set of the same make as his own. Similarly, users of electric cookers and heaters may do no end of harm by spreading the idea that electric heating and cooking leave much to be desired. Adequate voltage is, of course, essential to secure the best performance from electric motors, although this is a matter of greater importance in the factory than in the home.

As regards the effect of low voltage on supply undertakings, the reduced watt consumption of lamps may be taken as 1·5 per cent. for each 1 per cent. reduction in voltage, and that of heating apparatus 2 per cent. under the same conditions. Water heaters take longer to impart the necessary temperature to the water without the consumption being materially affected. Domestic loads generally have a very high power factor, but on systems with a substantial motor load the conditions may, of course, be very different. Tariffs designed to bring about an improvement in power factor are then often desirable, for an excessive amount of wattless current has anything but a beneficial effect on voltage. By basing the charge on the kVA demand, large consumers are encouraged to install motors which do not draw a lagging current, or to provide special power factor correcting devices, such as phase advancers and condensers. Power factor improvement, however, scarcely comes within the scope of these articles, although it is important to be certain when applying regulators to distribution systems that the magnetising kVA and leakage reactance of the apparatus are not unduly heavy. There is a tendency, we find, on the part of some manufacturers to criticise their competitors' goods on these and other grounds, but supply engineers must be left to specify exactly what they require, and to ensure before purchasing a regulator that it will have reasonably low losses and magnetising kVA, and that it will be capable, if necessary, of working satisfactorily on a low power factor load.

Much can, of course, be done to secure a steady voltage by correctly choosing the lay-out of mains, feeders and sub-stations, but notwithstanding careful design the voltage control problem exists on many networks. In some cases the load has grown much more rapidly than was expected, and in consequence of consumers' complaints steps have had to be taken to improve the voltage regulation without delay. Variations in pressure at consumers' terminals may be due to one or a combination of three main causes, *i.e.*, bulk supply variations, distribution drop, and out-of-balance loading.

Regulator Advantages.

Articles on A.C. regulators appeared in The Engineer during April and May, 1926; and on "on-load" transformer tap-changing gear (which can, of course, be applied to distribution transformers) during July and August of 1929; but within more recent times there have been new developments, and the demand for distribution regulators has become more widespread. In some cases it has been found necessary to employ some kind of voltage control apparatus which operates automatically. Such regulators may be installed rapidly without interfering with existing arrangements, can be kept in stock ready for use when they are required, and they often afford a cheaper and more convenient method of improving the voltage regulation than that of providing new feeders. The correct solution to the problem will, of course, depend on circumstances. In a district with a large voltage drop or rapidly increasing load a new sub-station will be the best solution, but experience shows that the desired results can often be secured with voltage regulators, which increase the capacity of mains and distribution lines, and extend the range of sub-stations without heavy outlay. Even on a new distribution network these regulators are claimed to be capable of reducing the initial cost, for the price of a regulator is practically negligible, compared with that of feeders and sub-stations. On new and existing networks regulators may be installed permanently or temporarily, according to the growth of load. Where the load is steadily increasing and new feeders and sub-stations will ultimately be required, regulators may be employed to maintain the pressure for a certain time. Under these conditions the economic case for regulators becomes a matter of comparison between the annual total cost of the apparatus and the saving in the capital cost of new sub-stations and mains.

The Economic Aspect of Automatic Voltage Regulators.

Although the cost of a distribution regulator such as an on-load tap-changing regulator may be as great or even greater than that of a transformer with which it is associated, the saving in the cost of distribution lines and cables, due to the greater permissible voltage drop, or, alternatively, the increase in permissible loading of existing lines and cables, when automatic regulation is adopted, may easily make this a matter of no importance. This was shown some time ago in a paper read before the Overhead Lines Association, by Mr. E. T. Norris, who analysed the model scheme rural distribution developed in Messrs. Dickinson and Grimmitt's paper on "The Design of a Distribution System in a Rural Area."* In the following table the cost of the various items is expressed both in pence per unit, and as a percentage of the total cost:

Rural Distribution Costs.

	Cost in pence per unit sold.		Per cent. of total cost.	
Capital charges—				
High-tension lines	0·181		14·84	
Transformers	0·025		2·05	
Switchgear	0·024		1·97	
Low-tension lines	0·066		5·43	
Services	0·048		3·92	
Total capital charges		0·344		28·21
Running charges—				
Purchase cost of losses	0·104		8·54	
Purchase cost of energy sold	0·586		48·00	
Overhead costs	0·186		15·25	
Total running charges		0·876		71·79
Total cost	1·22	1·22	100·0	100·0

It will be perceived that the capital cost of transformers represents only 7 per cent. of the total capital charges and only 2·05 per cent. of the total cost of supplying energy. Hence it is clear that even if regulators are as expensive as transformers there is no reason for alarm. To emphasise the point more strongly, Mr. Norris considered the effect of equipping every transformer on the model scheme having a capacity greater than 15 kVA with an automatic regulator, a scheme which would make the total cost of the regulators one-third of that of all the transformers. Thus the capital cost of the regulators would be 0·33×7·3=2·4 per cent. of the total capital charges, or 0·33×2·05=0·68 of the total cost of supply. In other words, on this typical scheme automatic regulators could be installed at every transformer station having a capacity greater than 15 kVA, with an increase in the total cost of supply of only 0·68 per cent., or 0·0082d. per unit.

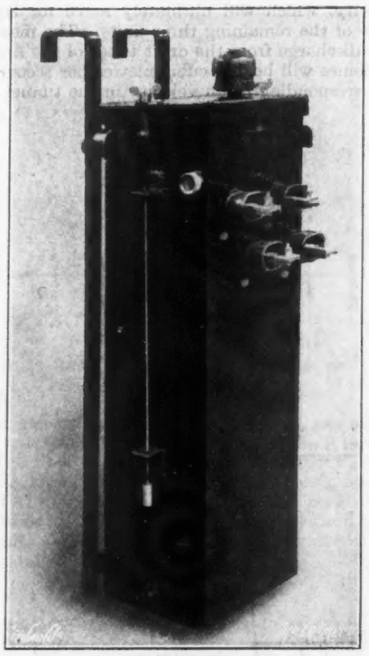

Fig. 1—Tail End Booster

Automatic Operation.

As regulators on distribution systems are usually installed in out-of-the-way places, or in unattended sub-stations, and as the system voltage is usually affected by individual components of the load, and is, therefore, subject to rapid and frequent variations which cannot be corrected by hand, automatic regulation is generally essential. But on large transformers handling a bulk supply the single components of the load are sufficiently numerous to have negligible individual effect on the voltage, and the regulating gear need only be operated infrequently as the load rises and falls. On-load tap changing equipments must, of course, be associated with transformers. It can, however, be applied to transformers with outputs as low as 100 kVA with small increase in the overall dimensions, and with negligible increase in the losses. But while it is fairly simple to design a multi-way switch suitable for infrequent tap changing, it is not so easy to make open-type switches or contactors which will last for long periods under automatic operating conditions involving, perhaps, several hundred operations per day without renewal adjustment and cleaning. Small self-contained automatic regulators suitable for any number of operations are suitable for distribution circuits, for they can be installed in any desired position. Irrespective of the input voltage or of whether the variations are due to load passing through the regulator, or to drop in the high-tension lines or other parts of the network, the automatic control gear can be set to maintain a constant output pressure. Moreover, if necessary, the regulators may be compounded in order that the voltage may increase with the load.

Current-operated Regulators.

Regulators such as the Ferranti patented current operated tail end booster, shown in Figs. 1 and 2, increase the voltage in proportion to the load passing through them. They are cheaper than the firm's independent voltage regulators, and have the additional advantage that in some cases at no-load the losses are zero. Notwithstanding that they will only compensate for voltage variations due to their own load, they have a wide range of application, although it is important when installing regulators to consider the cause of the voltage variations that are being experienced. Regulators can, of course, compensate for drop in transformers as well as in cables and overhead lines, and if desired transformers can, therefore, have greater reactance and lower short-circuit currents. Small transformers then become cheaper. Similarly, less expensive switchgear may be employed owing to the reduced short-circuit current, particularly in the case of cable distribution.

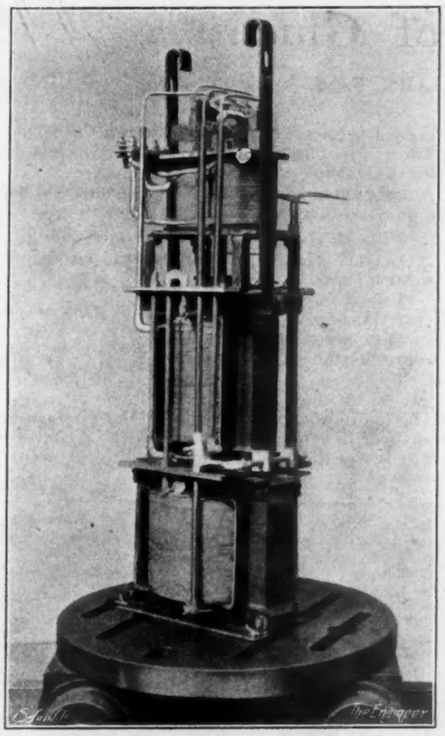

Fig. 2—Tail End Booster Removed from Case

One of the special features claimed for the patented tail end booster made by Ferranti Ltd., of Hollinwood, Lancs., is that as it does not demand the use of a sensitive voltage relay, the relative infrequency of operation, as compared with voltage-controlled boosters, permits of much larger voltage steps. The standard tail end booster gives a 6 per cent. boost in two 3 per cent. steps, the first coming into operation at about half-load, and the second at about three-quarters load, but larger or smaller steps can be provided if desired. A small transformer, a reactor, and two solenoid-operated mercury tube switches constitute the complete equipment, which is oil-immersed in a common tank, suitable for outdoor service. In the no-boost position of the regulator there is an absence of no-load losses, and since this is usually the condition prevailing during the majority of the working hours, this feature is considered to be one of considerable importance.

The increase in load that is made possible on an existing distributor by the installation of a tail end booster depends on the point at which the additional load is to be connected. If the new load is distributed along the existing line and no extension is necessary, the increase is estimated by Ferranti, Ltd., at about 67 per cent., but even if the new load can only be obtained by extending the line, the increase is unlikely to be less than 30 per cent. On a long distributor these cheap tail end boosters may be inserted at suitable intervals, but the number which may be employed is limited to two or three. When such boosters are used in series theory indicates that the amount of boost should be graded, each booster giving approximately two-thirds of the boost of the preceding unit. The third booster will, therefore, give less than half the boost of the first and the lack of standardisation will be inconvenient. On the other hand, if a standard boost is employed, the increase in load allowed by the addition of each succeeding booster becomes rapidly smaller unless the maximum voltage variation is allowed to increase. Under current control the frequency of operation is so low that a much larger voltage step is allowable and the number of steps necessary is correspondingly reduced. When the number of steps is limited to two great simplicity is secured, as interlocking can be almost completely eliminated.

Although the separate phases of a three or four-wire unbalanced circuit may be regulated individually by using the necessary number of independent single-phase units, it is preferable and generally no more costly to employ a three-wire single-phase or polyphase booster in conjunction with a separate static balancer. As in general the most suitable position for the former is farther from the substation than that of the latter, it is recommended that the two units should be kept distinct. As the load grows on a three-wire single-phase or four-wire three-phase distributor, a condition is reached under which the voltage at the tail end falls at times to the minimum allowable, and if this fall is largely brought by drop caused by an unbalanced load, the installation of a static balancer may permit of about 25 per cent. increase in load before the voltage again falls to the minimum permissible. The next step in the development of the system may be the installation of a tail end booster, which, if placed in the ideal position at the outset, will call for no further attention. This ideal position depends on the final conditions when the limit of voltage drop is reached.

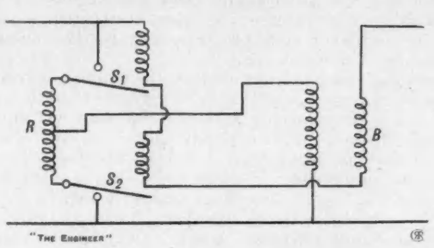

Fig. 3—Tail End Booster Connections

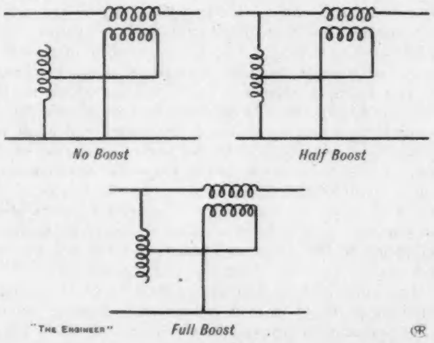

Fig. 4—Tail End Booster Step Connections

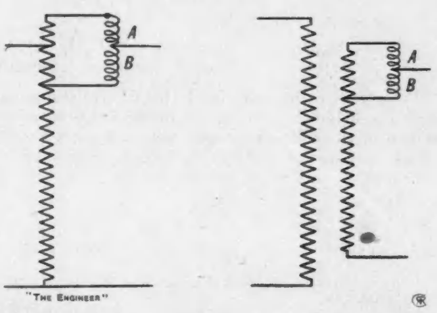
If the full allowable drop is, say, 9 per cent., and the boost 6 per cent., the limiting condition will be reached when the total drop is 15 per cent., and this condition can only be dealt with satisfactorily if the booster is placed at the point at which the drop is 9 per cent. If it is too near the sub-station, consumers immediately beyond it will at times receive too high a voltage, while if it is too far out, consumers immediately preceding it will get insufficient voltage. Before installing a tail end booster it is desirable to consider what the final distribution of load is likely to be, and at what point the unboosted voltage will first reach the minimum allowed. If at the time of installation the information available is insufficient to enable such an estimate to be made, the makers of these boosters recommend that the apparatus should be installed in the first instance at the point at which the maximum voltage drop is two-thirds of that at the tail end of the distributor.



Figs. 5 and 6—Auto and Double Winding "Apex" Regulators

The two solenoid-operated switches used on the primary side of these boosting transformers are of the mercury tube type. Similar switches have undergone full load life tests of two million operations, and have been successfully used for some years on automatic tap changing gears operating between 200 and 300 times a day. It is well known that these switches have no open contacts, and as they need no maintenance, they are immersed in the oil-filled tank together with all the other apparatus. The switches used are capable of dealing with the short-circuit current of the distributor. A "bridging impedance" is employed to prevent the opening of the circuit during the operation of the switches, and it also acts as a 2/1 auto-transformer to give the intermediate 3 per cent. boost.

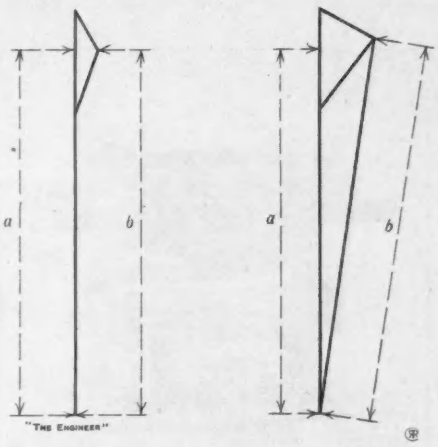


Fig. 7—"Apex" Regulator Vector Diagrams

Principle of Operation.

A two-wire single-phase unit is shown in Fig. 3, in which B is the booster transformer, with its secondary winding in series with the line. R is the tapped reactor, and S_1 and S_2 the mercury switches, the former being arranged to close at half load and the latter to open at about three-quarters load. Although the operating coils of these switches are normally fed through a current transformer, for the sake of clearness they are shown connected directly to the circuit. At light load, when both plungers are in the lowered position, only switch S_2 is closed, and it short circuits the primary winding of the booster through part of the reactor winding, as shown in the top left-hand diagram of Fig. 4, with the result that the line does not receive a boost. When, however, the load reaches a value that necessitates a rise in the tail end pressure, the switch S_1 closes, and connects the full reactor winding across the supply, as shown in the top right-hand diagram, Fig. 4, so that it acts as an auto-transformer and applies half voltage to the primary and thus causes the booster to give half the maximum boost. When the load increases still more, the switch S_2 opens and leaves the primary connected across the line, so that it receives full pressure and the booster gives the maximum boost, as indicated in the lower diagram—Fig. 4. As the load falls, the switch S_2 closes first and later S_1 opens, the two switches being interlocked so that they cannot open simultaneously. Means for setting the operating current of each switch to suit circuit conditions are also provided. The kVA of a tail end booster is the maximum load which can be passed through it, but as the booster will usually be installed at least half-way along the

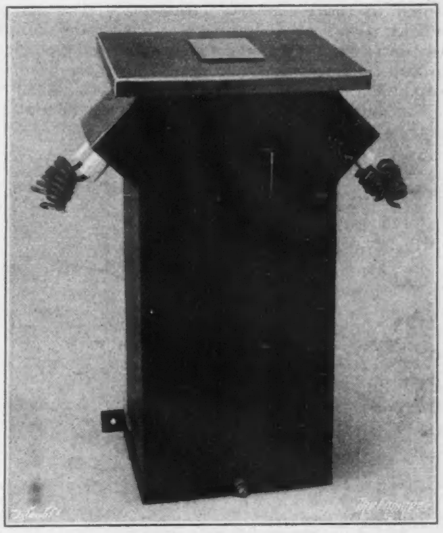

Fig. 8—"Apex" Regulator

distributor, the maximum load on the latter will be at least twice the rating of the booster, so that a 25-kVA booster will deal with a 50-kVA distributor. Standard single-phase, two-wire boosters are made for 10-kVA, 15-kVA and 25-kVA and single-phase three-wire and three-phase four-wire boosters for 25 kVA, but boosters for other kVA ratings and ranges of boosts other than 3 and 6 per cent. are also made. As in all cases the tap-changing switches are on the primary side of the transformer they only handle very small currents.

THE "APEX" REGULATOR.

A simple regulator which is being used with success on lines with approximately unity power factor is made by the Foster Engineering Company, Ltd., of Apex Works, South Wimbledon. Like other current-controlled regulators, it will give with constant supply pressure an increase of voltage with increase of load, or, alternatively, a steady secondary voltage. The regulator can be applied to the windings of a double-wound transformer, but is also made in the form of an auto-transformer booster, the amount of boost being determined within the limits of the apparatus by the amount and nature of the load connected to the secondary terminals. There are no moving parts, and the apparatus is therefore simple. Any desired ratio between the primary and secondary no-load pressures can be arranged for in the ordinary way.

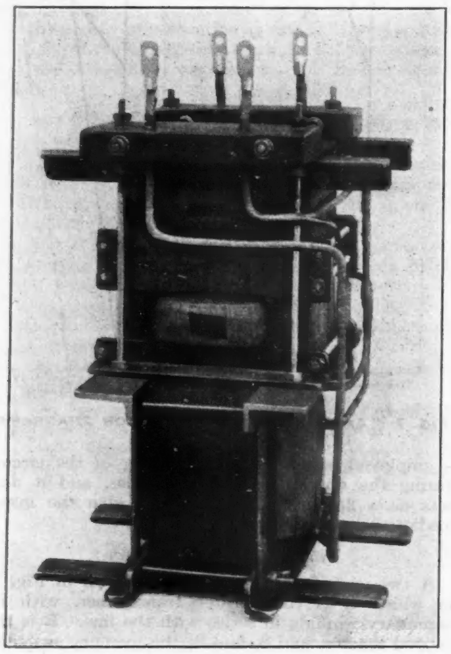

FIG. 9—"APEX" REGULATOR REMOVED FROM CASE

The auto and double-wound arrangements are shown in Figs. 5 and 6 respectively. It will be seen that in each case the transformer winding is tapped and the winding is designed to give a maximum voltage in excess of that required in the secondary circuit. Two reactances A B are connected to the secondary, as shown, and the tapping point at the centre forms one of the secondary terminals. Under no-load conditions, these reactances act as a potential divider, which is arranged to ensure that the desired secondary pressure is obtained at the outgoing terminals. The reactance A has a closed iron circuit, and is designed to work with a magnetic induction that prevents its terminal voltage greatly increasing when the load current passes through its winding. The other reactance B, however, has an air gap, so that under load there is a considerable increase in the voltage across it, and it carries a much smaller proportion of the load current. When a load of approximately unit power factor is connected to the secondary terminals the main secondary circuit may be considered to consist of the closed core inductance in series with the load resistance. Thus there is a considerable angle between the vectors of load and inductance volts, and these two vectors, together with that representing the transformer secondary volts, form a triangle. The inductance vector swings outwards from the no-load position (as shown in Fig. 7), but, by reason of the design of A, its length does not greatly increase, although the inductance is now carrying a much heavier current. The pressure applied to the second inductance has increased considerably, but, owing to its design, the current in this inductance only rises proportionally to the increase in volts at its terminals.

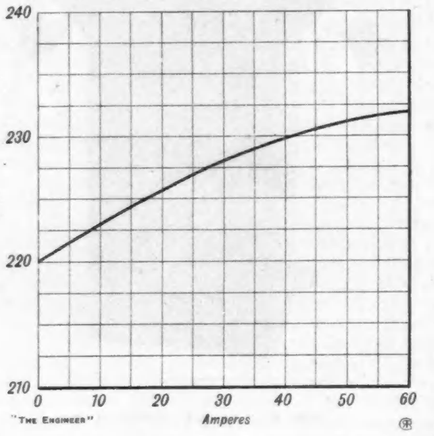

FIG. 10—"APEX" REGULATOR PERFORMANCE CURVE

Owing to the proportioning of the two inductances, the secondary pressure on load is greater than that at no load, but this only applies if the load has unity power factor. With a purely inductive load, there would be a drop in voltage, for in this case there would be two inductances in series across the transformer secondary, and their voltage vectors would be more or less in line with one another. Thus, as the load power factor decreases below unity, the boosting effect of the regulator diminishes. Moreover, as the vector diagrams, Fig. 7, show, there is a small phase angle between the primary and secondary volts, and although this is not sufficiently great to affect the power factor of the supply seriously, a circuit provided with one of these regulators cannot be paralleled with another circuit without a similar regulator. The apparatus may, however, be employed for maintaining the pressure on single supply circuits, such as a dead-ended "Tee off" from a ring main or on any other distributor not interconnected with other parts of the system, or for individual services from a distributor. Provided the load is non-inductive, the useful range of the regulator is at present up to 7½ per cent. increase in pressure from no load to full load, and the maximum boost can be arranged for any desired value within this range. The regulators are also supplied for use on high-tension mains. Fig. 8 shows one of these "Apex" regulators complete; Fig. 9 the regulator removed from its case, and Fig. 10 a characteristic curve based on a test in which the primary pressure was maintained constant at 220 volts, while the current was increased from 0 to 60 ampères. In considering the possibilities of this regulator, it should be remembered that, like Ferranti tail-end boosters, its action depends on the current passing through it, and it will not deal with bulk supply variations. It is, however, made for single or polyphase circuits, and can be used under the conditions mentioned on three-wire single-phase, four-wire three-phase, or any other ordinary A.C. distribution system.

(To be continued.)

Manufacture of Glucose.

By A. E. WILLIAMS, F.C.S.

ALTHOUGH more than a century has passed since the discovery by Kirschoff that a sweet syrupy liquid could be produced by the action of sulphuric acid on starch, very little progress had been made in the methods of manufacturing such a product until the post-war period. The large number of processes patented during the past ten years bears testimony to the interest which is now being taken in this branch of industry. Whilst the fact that pure crystal sugar is now prepared on a large scale from what was formerly waste vegetable matter is evidence of the remarkable advance resulting from the application of engineering and chemical science to the industry. In this article the object is to give a brief account of the present-day methods of glucose making, with special reference to the principal plant and machinery used therein.

Any material containing substance of the general formula $(C_6H_{10}O_5)n$ is a potential source of glucose. This material is present in the form of either starch or cellulose in nearly all vegetable matter. The various cereal grains, for example, all contain a large proportion of starch, whilst wood is rich in cellulose. What is at present a less important raw material for glucose making is found in the form of glucosides, substances of very complex formulæ, which are also present in most vegetable matter. The value of *n* in the formula for starch $(C_6H_{10}O_5)n$ is at present unknown. Some investigators have the opinion that it has a value of about 30; others place the number as high as 100. However, by the use of empirical formulæ the hydrolytic change by which the starch molecule combines with water to form sugar, under the influence of an acid catalyst, may be expressed in two stages, as follows:—

$$\underset{\text{Starch}}{2\,(C_6H_{10}O_5)} + \underset{\text{Water}}{H_2O} = \underset{\text{Maltose}}{C_{12}H_{22}O_{11}}$$

$$\underset{\text{Maltose}}{C_{12}H_{22}O_{11}} + \underset{\text{Water}}{H_2O} = \underset{\text{Dextrose (glucose).}}{2\,(C_6H_{12}O_6)}$$

Prior to the formation of the intermediate sugar maltose, other dextrinous products are produced, as shown in the following table, which depicts the chief substances in the order of their formation during the action of an acid on starch.

TABLE I.

Product.	Formula.	Trade name.
Soluble starch	$2\,(C_6H_{10}O_5)$	Soluble starch
Amylo-dextrins	"	
Erythro-dextrins ..	"	Commercial dextrin
Achroo-dextrins	"	Liquid glucose
Maltose	$C_{12}H_{22}O_{11}$	Solid glucose
Dextrose	$2\,(C_6H_{12}O_6)$	Crystal glucose

When the raw material for glucose making consists of wood pulp, sawdust, or other waste vegetable matter, it generally receives a preliminary treatment to convert the cellulosic or starchy material partly into dextrinous substances, and so facilitate its subsequent conversion into glucose. This preliminary treatment often consists of warming up the raw material and then mixing in a small quantity of very weak hydrochloric acid solution, the material being afterwards spread out in thin layers to dry.

Another method of treating sawdust, &c., is to agitate it thoroughly in a vessel equipped with an efficient stirring apparatus, while a stream of dry hydrogen chloride gas is blown through the mass. The gas has the effect of breaking down the cellulose to a material of lower molecular weight, which is thus more easily converted to glucose.

In the production of glucose on a commercial scale the processes may be divided into definite stages as follows:—

(1) Conversion of the raw material into a weak sugar liquor.
(2) Neutralisation of the acid catalyst.
(3) Decolorisation of the sugar liquor.
(4) Concentration of the liquor.
(5) Crystallisation of the liquor.

CONVERSION PROCESS.

The hydrolysis, or conversion of the raw material into sugar, is effected in an autoclave or converter, which is essentially a pressure vessel constructed of suitable material to withstand the action of the acid catalyst used. For low acid concentrations, which are used in the conversion of starch to glucose the converter may be constructed of copper; a vessel of steel, homogeneously lined with lead, being usually more suitable for higher concentrations of acid, which must necessarily be used when the raw material is other than starch. Fig. 1 depicts a glucose converter constructed in copper by Blairs, Limited, of Glasgow. This vessel is 5ft. in diameter by 7ft. in depth, having a copper body ½in. thick riveted to the main body at the circumferential seam. The vertical seam on the body is also riveted. The vessel is fitted

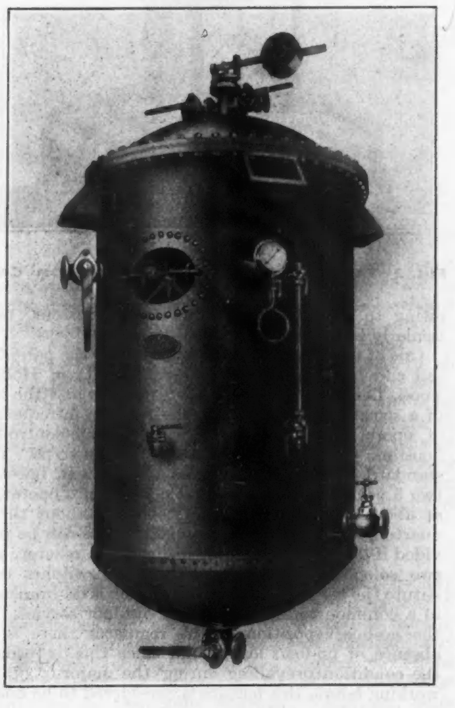

FIG. 1—GLUCOSE CONVERTER

with a copper dished dome, flanged to suit the body, and the main joint is complete with machined mild steel reinforcing jointing rings. Inside the converter is a steam coil of copper perforated to allow steam to be blown into the raw material and supported by the necessary stay supports. Outer fittings consist of a manhole with a heavy cover and a seat riveted to the bottom; inlet and outlet connections for the glucose material; steam stop valve; safety valve and air cock; pressure gauge and syphon; water and acid inlet cocks; and a sampling cock. The whole is carried on four heavy cast iron brackets fitted to the main flange. Such a converter is designed for working pressures up to 50 lb. per square inch.

Sulphuric acid was formerly in general use as a catalytic agent, being afterwards neutralised with powdered limestone, thus producing the insoluble calcium sulphate or gypsum, which was practically all removed by filtration of the liquor. The last traces of gypsum, however, were always difficult to remove, and this led to the formation of gypsum encrustations on the evaporator tubes during the concentration of the liquor, so lowering the efficiency of the evaporator appreciably. In modern practice hydrochloric acid is substituted for sulphuric acid and neutralised with soda ash, the resulting product being common salt, which is perfectly soluble in the liquor and is allowed to remain.

The raw material in admixture with a copious supply of water is first run into the converter and the necessary amount of acid catalyst is added. Steam at the required pressure is then blown into the mixture, and for a few minutes is allowed to blow through the vessel to atmosphere. The outlet valve at the top of the vessel is then closed, thus causing the pressure inside the converter to rise gradually until it equilibrates that in the steam supply line. By simple chemical tests on samples of the mixture drawn at intervals from a small cock in the base of the converter the progress of the hydrolysis may be ascertained. The total time occupied in converting the material to sugar is usually under one hour. It is not always the object to convert the whole of the batch into dextrose itself. From a glance at Table I. it will be seen that the grades known as liquid glucose and solid glucose respectively also contain some dextrin and maltose. So that in the production of these grades a complete conversion of the raw material to dextrose is not necessary. Only when crystal dextrose is to be produced is it essential to effect the conversion as completely as possible, so that the minimum of dextrin and maltose shall be present to interfere with the crystallising of the liquor. In practice it is not possible to produce a final product containing 100 per cent. dextrose, for before this desirable state can be achieved some of the dextrose first produced begins to decompose or revert.

The maximum proportion of dextrose sugars obtainable from a good quality starch depends on the steam pressure in the converter and the percentage of acid used. Modern practice is to use the minimum amount of acid and to increase the pressure accordingly, thus curtailing appreciably the length of time required for conversion and ensuring a lighter coloured liquor. The effect of pressure on the velocity of hydrolysis of starch to sugar may be noted by reference to Table II., the data for which was compiled from a series of experiments carried out in a small semi-commercial autoclave. Throughout this series of tests a definite proportion of acid, 0·4 per cent., was used.

TABLE II.

Batch No. ..	1	2	3	4
Temperature C.	122	135	142	148
Pressure in lb...	15	30	40	50
Duration of treatment ..	Per cent. conversion	Per cent. conversion	Per cent. conversion	Per cent. conversion
15 minutes ..	16	31	36	43
20 minutes ..	26	47	52	60
25 minutes ..	35	58	65	72
30 minutes ..	42	67	72	81
35 minutes ..	50	75	78	86
40 minutes ..	57	83	84	90*
45 minutes ..	61	91	92	90
50 minutes ..	62	96	96	90

* Point of maximum dextrose content.

From Table II. it will be clear that the most economical pressure when using 0·4 per cent. of catalyst would be 30 lb.; no advantage being gained by employing 40 lb. Whilst 50 lb. pressure is definitely disadvantageous, as reversion products are formed after 90 per cent. conversion, and very probably at an earlier stage, the loss due to reversion being counterbalanced for a time by the further conversion of dextrin. Apparently when the percentage of reversion products has attained a definite figure under these conditions of hydrolysis, any further formation of dextrose is inhibited. At 50 lb. pressure the maximum content of dextrose which can be produced under these conditions has been formed after 40 minutes' treatment; thereafter, the glucose content gradually diminishes, whilst the proportion of reversion products is enhanced. Although in the initial stages the velocity of hydrolysis is slightly accelerated for the higher pressures, the reaction is retarded as the proportion of sugars increases. Subsequent experiments have shown that by increasing the percentage of acid catalyst to 0·8 per cent. a similar reversion of sugar is experienced at lower pressures, *i.e.*, 35 lb. to 40 lb., and by decreasing the percentage of acid to 0·2 per cent. the economic working pressure would be raised to about 50 lb. It would appear therefore that for efficient and economic working the amount of acid catalyst to be used varies inversely with the pressure employed, within a limited range of pressure and percentage acid content.

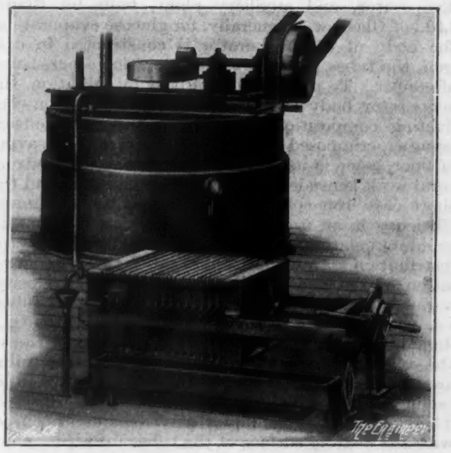

FIG. 2—DECOLORISING APPARATUS

NEUTRALISATION.

Two methods are in use for transferring the weak sugar liquor from the converter to a vessel wherein the acid catalyst is neutralised. One consists of first releasing the pressure in the converter and then pumping the liquor, with a direct coupled rotary pump, into the neutralisation vessel. In this method a considerable fall in temperature occurs in the converter immediately the pressure is released, so that cooling of the liquor is not usually necessary before neutralisation. The other method consists of utilising the pressure in the converter for forcing the liquor—*vid* a tubular cooler of 1½in. copper tubes, around which cold water circulates—into the neutralising vessel. In this case no pump is used, but a cooler is necessary as no temperature reduction occurs in the converter.

Generally, a copper cylindrical vessel with a conical bottom and efficient stirring equipment is used for the neutralising of the liquor. This is accomplished by gradually adding, to avoid excessive foaming, soda ash, which converts the hydrochloric acid into harmless common salt. For two reasons a slight trace of acidity is allowed to remain in the liquor. In the first place, a faintly acid liquor is more easily decolorised; secondly, a perfectly neutral liquor will rapidly foul the tubes of the evaporator during the concentration of the liquor, but a trace of acidity tends to keep the tubes clear of adhering sugar.

DECOLORISATION.

Until quite recently the removal of colour from the sugar liquor was accomplished by allowing the latter to percolate through a deep bed of charcoal, the emerging liquor being passed by a rotary pump to the top of the layer again for re-percolation; this process being continued until the liquor was sufficiently light in colour. With the advent of activated carbon—a material of very efficient decolorising capacity—another type of decolorising plant has been adopted. The advantages of this improved method of removing the colour from the liquor are that the process of decolorisation is speeded up, the loss of sugar liquor by absorption in the carbon is infinitesimal, and no revivification of the decolorant is necessary. In this method the glucose liquor is pumped from the neutralising vessel into the mixing tank seen to the rear of Fig. 2. The stirrer is then set in motion and about ½ per cent. (by weight) of activated carbon is added. This mixture is thoroughly stirred for one hour or so; then the whole is pumped through a filter press, seen in the foreground of Fig. 2, the carbon being retained by the press whilst the clear liquor passes out through the taps at the side of the press. The glucose decoloriser illustrated is built by Rose, Downs and Thompson, Ltd., Hull, and consists

essentially of an open top bleaching vessel, so designed as to ensure a very intimate mixing of glucose and carbon. The pan is constructed of mild steel plates, and fitted with agitating gear operated by a belt through bevel wheels from the horizontal shaft. Paddle type agitators are fitted to the vertical shaft, which is carried in a footstep bracket specially arranged so as to keep the glucose outlet clear. The pan is arranged with an outside steam jacket, and also with a dry coil and the necessary supports. A gland cock is provided for the liquor outlet and the steam jacket is fitted with safety valve, air relief valve, steam gauge, and steam trap. Generally, the filter press is of the flush plate and distance frame type, the plates and frames being of cast iron. The glucose enters by a totally enclosed passage formed in lugs external to the filter cloth joints, and thus the cloths need not be cut for the admission of the liquor to the press. Similarly, the filtrate outlet is made in cuffs on external lugs. Cocks for first-running liquors—which are usually contaminated with carbon and so have to be passed back to the mixing pan—are provided at the bottom of each plate, these being used on starting the press and then closed, thus ensuring that no air contamination of the glucose is possible. A main drain and air cock are provided to allow of rapidly draining the press on completion of the batch. The side bars holding the plates and frames of the press are of mild steel fitted into the cast iron head and foot stocks; whilst the main closing screw is made of mild steel with a buttress thread. This screw may be operated by bar, ratchet gear, or geared hand wheel; in the larger sizes of press the screw is replaced by a hydraulic ram. The liquor is forced through the press by means of a steam-driven horizontal duplex pump, the ends of which are of cast iron, fitted with steel pump rods, cast iron ring buckets, and gun-metal valves and seats.

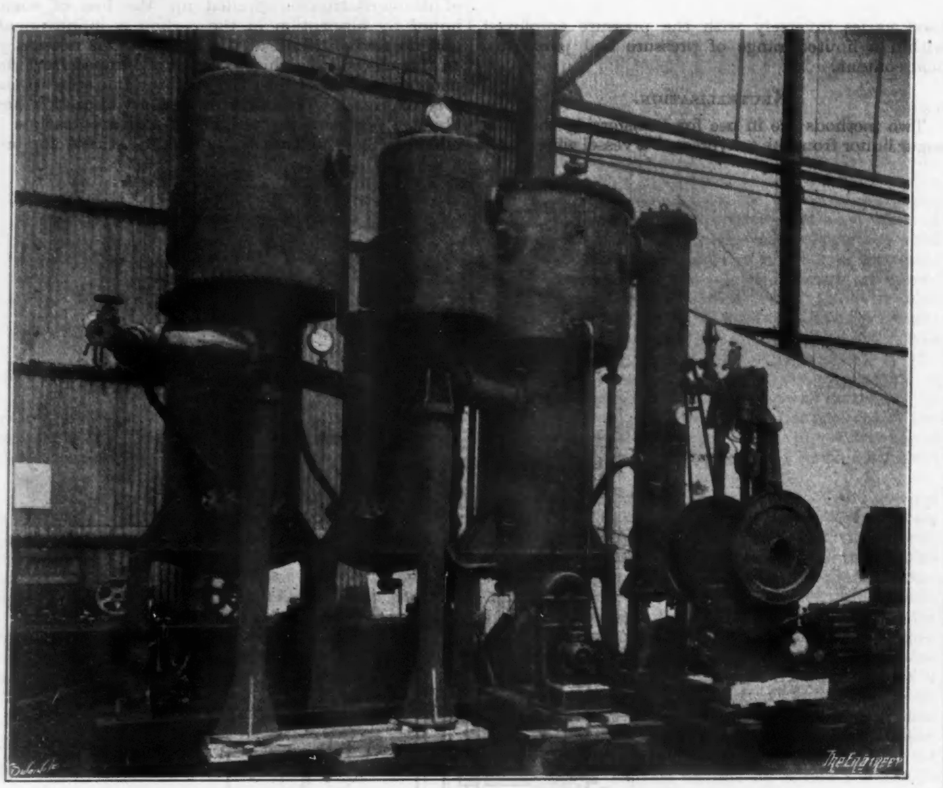

FIG. 4—MULTIPLEX TRIPLE EFFECT EVAPORATOR AND AUXILIARY PLANT

CONCENTRATING THE LIQUOR.

There are three different types of glucose produced on a commercial scale, viz., liquid, solid, and crystal glucose. The first grade is in the form of a thick syrup, obtained by evaporating the excess water from the weak decolorised liquor until the latter has a specific gravity of about 1·410. Solid glucose is a dense compact substance, obtained when the concentration process is carried on until the liquor has a specific gravity approaching 1·500. Crystal glucose results from evaporating the weak liquor to a specific gravity of about 1·360, then crystallising the cooled liquor.

The choice of evaporator for glucose concentration must necessarily vary with individual requirements. Such factors as the steam and water supply in the factory, capital cost, and the type of glucose it is required to produce must all be considered. In the evaporation of the liquor it is usually possible to use exhaust steam from pumps, engines, and processes in the factory. Usually, the most economical method of removing the excess water from the liquor in terms of steam consumption is by the adoption of a multiple effect evaporator operating under vacuum. On the other hand, where the initial outlay on the plant must be kept low, and at the same time a good supply of live steam is available in the factory, a single and double-effect non-vacuum evaporator is suitable. In both types of plant it is often advantageous to fix a steam economiser on the evaporator, which effects a great saving of steam by compressing part of the exhaust vapours from the liquor and returning it to the evaporator. Fig. 3 illustrates the general lay-out of a Multiplex Triple-effect Film Evaporator, and auxiliary plant, built by Blairs, Ltd., of Glasgow. Generally, for glucose evaporation, the body of the evaporator is constructed in cast iron, the tubes in which the evaporation occurs being of copper. To prevent loss of heat by radiation, the evaporator body is efficiently lagged with non-conducting composition. Owing to the three effects being superimposed one above the other, a great saving of floor space is made, and no elaborate steel structural work is needed to support the plant beyond the short cast iron columns. To obtain the maximum efficiency in an evaporator, it is necessary to ensure rapid circulation of the liquor and uniform heat distribution. It will be appreciated that the circulation of the liquor, and consequently the velocity, varies with the proportions of the evaporating tubes, *i.e.*, with the ratio of the heating surface of the tube divided by the cross section—or carrying area—of the tube. In the Multiplex evaporator the tubes are of such a precise diameter and length that rapid boiling with consequent circulation is ensured. Therefore the glucose liquor only remains in contact with the heating surface of the tubes for a very short time, its entire passage through the plant occupying only a few minutes, thus preserving the quality of the glucose.

In the operation of the plant the weak decolorised glucose liquor is heated in a preheater tank to a temperature of about 90 deg. Cent., either by means of exhaust steam or by the hot vapours from the evaporator. This liquor is then fed into the first effect, A, Fig. 3, the quantity being regulated by means of a special valve with indicating device; a steady and constant feed being maintained by means of an automatic controlled float valve in the tank D. This is an advantage over feeding by a pump, as it reduces working expenses, and obviates the trouble sometimes caused owing to irregular feeding due to the pulsations of the feed pump. The glucose, if fed in at a temperature closely approaching its boiling point, rises to a uniform height in the evaporating tubes, and immediately begins to evaporate, giving off its water vapour. As soon as ebullition takes place at the lowest portion of the heating tubes, the vapour forms bubbles initially, but as its volume steadily increases with a corresponding high increase in velocity the liquor attaches itself to the tube walls in the form of a uniform film-like layer, the vapour forming a centre core, and both liquor and vapour leave the tubes at the top at a very high velocity. On account of this high velocity of the liquor through the plant the maximum heat transmission is obtained. The liquor and vapour on leaving the evaporating tubes are projected at high speed against the baffle plate, and through the tubular connection into the separator, where the liquor is separated from the vapour by means of the specially devised foam separator which ensures perfect separation and freedom from entrainment. The liquor is carried down on to the baffle plate, and is then drawn up owing to the reduced pressure into the second effect, through the internal liquor pipe, and into the liquor chamber of the second effect. The vapour passes into the heating chamber of the next effect through the central intake, thus ensuring equal distribution in the vessel, so that all the heating surface is heated with the utmost uniformity, resulting in high efficiency. The concentrated liquor—at the required density—is removed from the last effect by means of a pump; but where conditions are suitable, this can be dispensed with, the liquor being discharged continuously under a barometric head. The condensed steam from the first chamber can be used for boiler feeding, or passed on into the second effect, where, on account of the low pressure in the chamber, it vaporises, and the heat it contains does further useful work. The condensed steam from the second effect is taken into the heating chamber of the third effect, where it also gives up some of its heat. All the vapour from the last effect is taken through the condenser, and the condensed steam from the heating chamber is either withdrawn through the condenser, or by means of a separate pump.

Fig. 4 shows another type of Multiplex Triple-Effect evaporator with auxiliary plant assembled in the workshops of Blairs, Ltd. In this plant the three effects are placed side by side, instead of being one above the other. A special feature of the plant is the introduction of a side separator into which the mixed liquor and vapour is passed immediately after leaving the top of the evaporating tubes, which permits of a very short "top header," with a hinged or other type of cover which is readily removable. On this being opened, and the bottom cover swung down on its hinges, the whole of the liquor side of the evaporator is exposed for examination or cleaning and the tubes can be brushed or scraped out immediately after the cessation of work, whilst the cleaners remain always in the open air. These advantages will readily be appreciated by all engineers who have had to deal with the ordinary type of vertical evaporator, for which several hours have usually to be allowed for cooling down, and even after that the cleaners have to enter the vessel by climbing through small manholes at the sides, and have then to work inside closed vessels which are still much too hot for comfort and for efficient working.

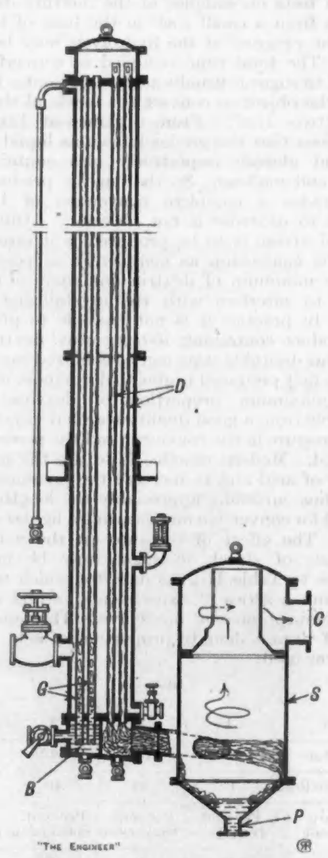

FIG. 5—KESTNER PATENTED FALLING FILM EVAPORATOR

B. Liquor Inlet Box.
G. Climbing Film Tubes.
D. Falling Film Tubes.
S. Separator.
C. Vapour Outlet.
P. Concentrated Liquor Outlet.

Another type of evaporator much used in the glucose industry is the Kestner Falling Film evaporator, made by Kestner Evaporator and Engineering Company, Ltd., London, and illustrated in Fig. 5. In this plant the weak glucose liquor enters at B and then passes into a series of 2in. copper tubes surrounded by steam; a climbing action immediately commences, the vapour from the heated liquor forming a core in the centre of the tubes, and carrying up a thin film of liquid round the inner surface of the tubes. When the vapour and liquor arrive in the upper box above the tube plate, they pass to the down tubes, the liquor passing down as a film, and the vapour forming a core in the centre of the tubes. The liquor and vapour now pass to the separator, where, by centrifugal action, the vapour passes through the upper outlet C to the condenser, and the liquor through the lower outlet P. This evaporator will remove when necessary from 70 to 80 per cent. of water from the glucose liquor in one passage through the plant.

Under certain conditions it is possible to effect a great economy in the evaporation of the glucose liquor by the utilisation of waste steam from the evaporator and other steam using processes in the factory, by compressing the vapours and thus increasing the heat available. Usually, a mechanical compressor is not so economical as the steam-jet type for this purpose, as the former requires a greater motive power to operate it. Fig. 6 illustrates a Kestner Falling Film evaporator fitted with an injector-compressor, in which A is the compressor; B, steam drier; C, evaporator; D, separator; E, feed pump; F, weak liquor inlet; G, high-pressure steam main; H, live steam inlet to compressor; I, waste vapour outlet; J, vapour suction pipe leading to compressor; K, pipe carrying mixture of live and exhaust steam; L, weak liquor inlet to feed pump; and M, wash-water inlet. A supplementary live steam pipe is provided for use when working without the injector-compressor, and the waste vapour then passes to atmosphere through the exhaust main I, which is throttled when the compressor is working. It will be obvious that the higher the pressure required in the mixed steam in K, the greater the proportion of live steam that must be used, and, therefore, the less the saving which can be effected through the compressor. For instance, assuming the waste vapour to be at atmospheric pressure, and the live steam at 100 lb. gauge pressure, the proportion of waste vapour in the mixture, and, therefore, the saving of live steam effected, will be:

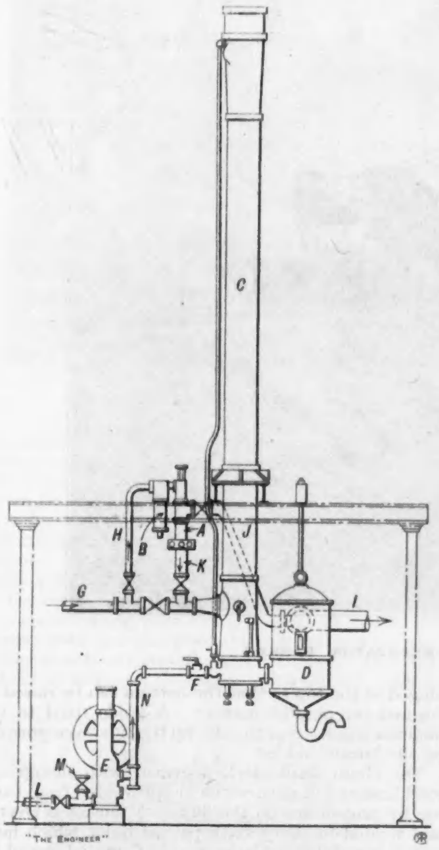

FIG. 6—KESTNER SINGLE EFFECT WITH INJECTION COMPRESSOR

C. Kestner Evaporator.
D. Kestner Separator.
E. Feed Pump.
F. Kestner Liquor Regulator.
G. Main Steam Inlet.
H. Auxiliary Steam Inlet to Injector Compressor.
I. Vapour to Atmosphere.
J. Auxiliary Vapour to Injector Compressor.
K. Mixed Steam to Evaporator
L. Liquor Inlet Valve Suction
M. Wash Water Valve Suction
N. Liquor to Evaporator.

	Per cent.
For mixed steam at 2 lb. pressure	64
For mixed steam at 5 lb. pressure	51
For mixed steam at 10 lb. pressure	29
For mixed steam at 15 lb. pressure	24

These figures, which show a substantial saving of live steam, are based on actual works' experience and not on short test runs, which frequently show much higher rates of saving. An important point is that, under all circumstances, the mixed steam is delivered in a perfectly dry condition, even if the live steam is wet, owing to the superheating of the live steam due to the "wire-drawing" action of the injector-compressor. It must be remembered in this connection that exhaust steam or vapour, whether from engines or evaporators, is always "wet" or supersaturated, and that therefore a pound of such vapour which has not been passed through the compressor has not the same heating value, due to latent heat, that is possessed by a pound of "dry" steam at the same pressure.

CRYSTALLISATION PROCESS.

For the purposes of crystal glucose the liquor is concentrated in the evaporator until a specific gravity of about 1·360 is attained. This liquor is then run into crystallising pans, which may conveniently be circular steel vessels of about 8ft. diameter by 3ft. deep, and provided with a jacket through which either cold water or steam may be circulated as desired. The liquor is cooled to a temperature of about 36 deg. Cent. by circulating cold water in the jacket. To induce crystallisation in the cooled liquor it is advantageous to add a sprinkling of "seed" crystals from a previous batch of glucose. Around these seed crystals other crystals are gradually built up from the liquor until the whole of the mass is in a semi-solid crystalline state. This is then transferred to a centrifugal machine which separates the crystals from the remaining liquor. The latter is generally sold as liquid glucose. From the centrifuge the crystals pass into a vacuum band dryer in which they are dried by being passed slowly, on endless belts, between steam-heated chambers.

Glucose is used largely in the confectionery, jam, and fruit-jelly trades, and especially in the manufacture of sweets and toffee, in which it is often the chief constituent. Large quantities are also used in the brewing industry. Other edible uses include the adulteration of honey, and the preparation of "caramel," obtained by heating glucose to about 200 deg. Cent. Caramel finds an outlet for the colouring of numerous edible liquids. Non-edible uses of glucose include the preparation of textile sizes, and adhesive pastes in general. Some idea of the increasing demand for crystal glucose may be gained from the fact that in the U.S.A. alone, the annual production of this type of sugar has increased in the last few years from 38,000 to over 400,000 tons.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

THE ENGINEER SALESMAN.

SIR,—Before the war it was beginning to be recognised that there was a very definite opening for trained engineers with a bent for the selling side, capable of following up inquiries and able to deal with both the sales and engineering problems that might arise. If my memory serves me well, THE ENGINEER was foremost in advocating such careers. The idea was that the men should be able to give an intelligent explanation to any point and to assist the prospective customer in any way that might be useful, both in furthering the sale and ensuring that the purchase would be successful at work.

Immediately after the war there was a considerable demand for such men, with the result that many first-class men took up the work, often very successfully, trade being then very different from its condition to-day. Firms of repute were willing to make a reasonable allowance towards out-of-pocket expenses. Some allowances were extravagant, which was a pity. It would have been better to keep expenses allowances low and be more generous in the matter of commissions, which would have suited the really earnest men best. Unfortunately, it attracted a class of person whose whole object was to collect as many expenses allowances as possible. Usually gifted with a very persuasive tongue (very useful in its right place), he could cajole an agency out of the principals of a firm, and then do as little work as possible in return. Pests of this type have done a great deal to ruin the prospects of the honest hard worker, so much so that the pendulum has swung in the opposite direction, and it has become increasingly difficult to get a representation carrying with it an allowance of any sort, even for the most reasonable amount.

Firms are only too willing to allow one to work on a purely commission basis, paying all one's own expenses. This, of course, is grossly unfair, because it means that the representative, if a good one, is building up a connection at his personal outlay for another firm. If he is successful, there is nothing to prevent his employer terminating the agency, and, if he wishes, taking up the work himself or passing it on to some favourite nominee. This actually happened to the writer. Would-be sales engineers should remember that if a firm is not willing to grant either a moderate allowance or a representation on a minimum commission basis, they have very little confidence in their own product, and on the whole are best left alone.

November 20th. SALES ENGINEER.

FRANCE AND MANCHUKUO.

SIR,—In connection with your leading article on Continental Industrial Plans and Monsieur Sarraut's ideas for international collaboration, it is interesting to note that France is taking very great pains to try and secure a footing in Manchukuo.

There is no doubt that there will be considerable developments in that territory, and it would appear that, although Japanese influence is paramount, the policy of the "open door" (more or less) will be followed, chiefly owing to the critical attention which is being shown by the whole world to see how far this profession of policy will be carried out.

Our French friends are certainly not backward in coming forward, and have had investigators on the spot for some time, representing powerful financial interests backed, it is said, by Government support.

From accounts of these activities, however, it would appear that there is little intention of carrying out Monsieur Sarraut's idea of international collaboration, in which case the competition among European—and American—manufacturers under conditions of monetary chaos, to which you refer, will continue, and be particularly severe for this potential market.

Incidentally, it is to be doubted whether British firms are taking the possibilities of developments in Manchukuo as seriously as they should; they have certainly so far not shown anything like the initiative and energy the French have, and the reason, one ventures to think, is a feeling that in spite of their protestations, the Japanese mean to see that although the front door may be open, the only one that will be of any use will be the side or tradesmen's entrance—and they will keep the key!

CHINA HAND.

London, E.C., November 17th.

SIXTY YEARS AGO.

IT is just over sixty years since horse-drawn tramways became established in this country. Naturally, it was not long before various designs of steam-propelled tramway cars were evolved. One such car, built in accordance with Grantham's patents, was illustrated in our issue of November 28th, 1873. We had attended trials of the vehicle two days previously on the tramway line "below Victoria Station and Vauxhall Bridge." The boilers and engines had been made by Merryweather's, but it would seem that the boilers failed to give a good account of themselves on the occasion of the trial. They could not "keep steam" properly, so we said, because they were too small for their work and possibly, also, because the crowded state of the car rendered their firing difficult. Our engravings show the car as a double-deck vehicle with a "knife board" seat on top, a central chimney, and a driving platform at each end. The vehicle was equipped with two sets of wheels, namely, four flanged wheels for running on rails, and four flangeless wheels which, when the others were raised by means of a steam cylinder, were intended to permit the car to run on an asphalt road. One pair of the flangeless wheels was mounted to turn about a central pivot for steering purposes. Two boilers of Field's patented type were mounted inside the body at the middle of its length, but they were enclosed in cupboards in order that no smell or heat might be transmitted to the interior of the car. They supplied steam to a single inclined cylinder slung underneath the lower floor. It is not clear how the cylinder transmitted its power to the wheels, or how the drive was transferred from the flanged to the flangeless wheels when the change was desired. Although the trial was not wholly successful, it afforded, we said, fair promise of better things in the future. The subject of steam tram locomotion was, we said, a large one, and we intimated our intention of dealing with it in an early issue . . . A note regarding improvements recently made in electric lighting by Mr. A. Ladiguin, of St. Petersburg, is of interest as foreshadowing in some way the modern gas-filled lamp. Hitherto, it was explained, one of the principal difficulties in the way of applying the magneto-electric machine for purposes of illumination resided in the want of steadiness induced by the rapid burning away of the two carbon points between which the arc was established. Mr. Ladiguin surmounted this difficulty by using only one carbon point, and by enclosing it in a sealed glass tube from which air had been exhausted and replaced by a gas which would not combine with carbon at a high temperature. It was stated that in use the lamp emitted a soft, steady light.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

LARCH POLES.

No. 513—1933. This specification has its origin in a request from the Forestry Commission that investigations should be made with a view to ascertaining whether home-grown larch was suitable for transmission poles. A large number of tests were carried out at the Forest Products Research Laboratory, Princes Risborough, and the results of these tests indicated that, with suitable treatment, the unfavourable characteristics of larch could be overcome.

In the Foreword to this Specification it is pointed out that the Committee was confronted with those unfavourable characteristics peculiar to larch which had militated against the use of poles of this species in the past, namely, the tendency for seasoning checks to become localised, rendering the pole unsafe for climbing with spurred climbing irons, and also the twisting that takes place at the top of the pole, occasioned by the presence of spiral grain. It was, however, considered now possible to control the former characteristic by suitable treatment, while the second, which is only of small account if the points of attachment of the conductor are close to the pole, can be eliminated by specification.

The specification includes tables of dimensions and deals fully with the methods of creosoting. In an Appendix are given some useful tables of ultimate breaking loads of larch poles.

The Public Works, Roads, and Transport Exhibition.

No. III.

(Concluded from page 503, November 17th.)

Hadfields, Ltd.

The main exhibit of Hadfields, Ltd., East Hecla Works, Sheffield, was the crushing and screening plant, typified by Fig. 35. which is capable of producing from 10 to 12 tons of road metal per hour. It is, it will be seen, a combination of a double-toggle crusher with two rotary screens and an elevator, so arranged on a wheeled underframe that the road metal is delivered sufficiently high to fall into carts alongside.

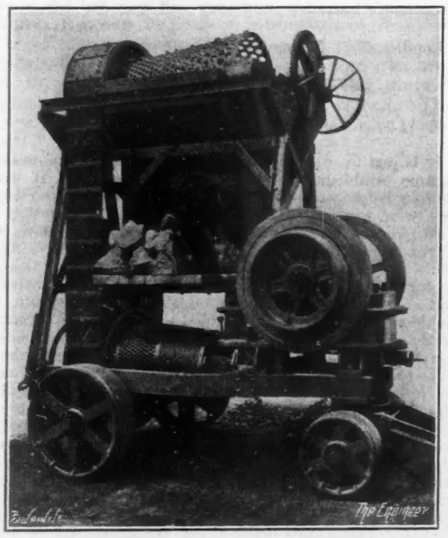

Fig. 35—Crushing and Screening Plant—Hadfields

The breaker has a jaw opening of 20in. by 10in., and is chiefly noteworthy on account of the fact that the frame is a single casting of the makers' toughened steel, which enables the weight to be reduced by 50 per cent., as compared with cast iron. The jaw stock and pitman are made of the same material, and the crushing faces of Era manganese steel. The latter are, of course, renewable. The crusher runs at 250 revolutions per minute, and requires about 25 horse-power. It delivers into the lower rotary screen, which has fine perforations for taking out small stuff that may be used for road surfacing. The oversize from this screen goes to the elevator, which is of the internal bucket type, and is raised to the top screen. It is there graded into two sizes and delivered into hoppers, from which it can be shot into carts. The oversize is returned to the breaker for further reduction. The total weight of the plant is about 252 cwt. Other exhibits on this stand included spare parts for crushers in manganese steel, non-corrodible steel road studs, and specimens of high-speed tool steel.

R. Broadbent and Son, Ltd.

There were two new machines on the stand of Robert Broadbent and Son, Ltd., Phœnix Iron Works, Stalybridge, one of which we illustrate in Fig. 36, while the other was a granulator for producing fine chippings. This latter machine is a jaw-breaker with a single toggle, but is characterised by the fact that an auxiliary lever and toggle transmit part of the thrust on the jaw stock back to the level of the excentric shaft, and thus relieve the rotating rubbing faces of some of the load. At the same time the movement of the jaw is such that the material being reduced is subjected to a rolling rather than a grinding action, and the production of fines is minimised.

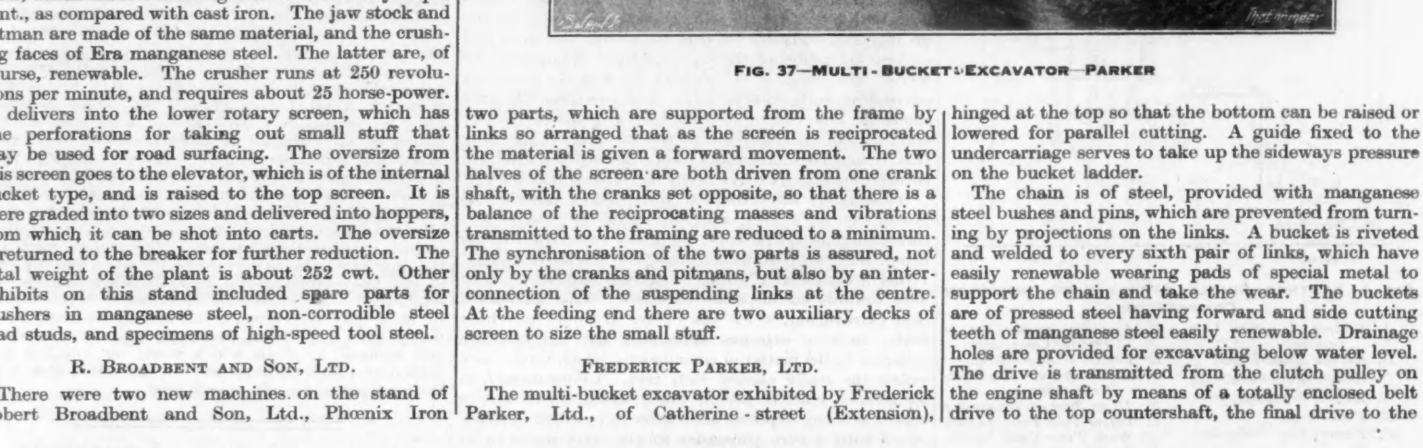

Fig. 36—Counterbalanced Shaking Screen—Broadbent

The shaking screen, which we illustrate, is put forward as an alternative to a rotary screen on the score that the screening plates are rectangular and flat, and consequently can be easily replaced as they wear away. The screening surface is divided into two parts, which are supported from the frame by links so arranged that as the screen is reciprocated the material is given a forward movement. The two halves of the screen are both driven from one crank shaft, with the cranks set opposite, so that there is a balance of the reciprocating masses and vibrations transmitted to the framing are reduced to a minimum. The synchronisation of the two parts is assured, not only by the cranks and pitmans, but also by an interconnection of the suspending links at the centre. At the feeding end there are two auxiliary decks of screen to size the small stuff.

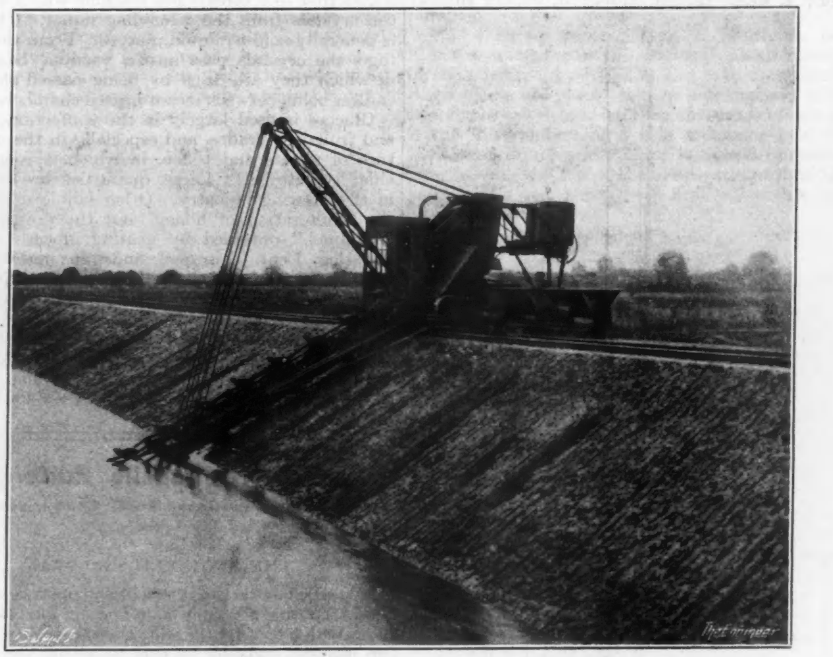

Fig. 37—Multi-Bucket Excavator—Parker

Frederick Parker, Ltd.

The multi-bucket excavator exhibited by Frederick Parker, Ltd., of Catherine-street (Extension), Leicester, and illustrated in Fig. 37, is not, of course, new in principle, as such machines have been used extensively on the Continent, but we believe that up to now few have been made in this country. It is what might be described as a land dredger, and comprises a bucket ladder supported from a carriage which also houses the oil engine. The ladder is a light but very strong lattice work, constructed of steel sections, gussetted and riveted together. Its length can be easily altered, and knuckle joints and a levelling extension can be added. The bottom angle sections of the framework act as guides to the chain, being fitted at the top, bottom and sides with easily renewable steel liners. On the top of the framework are rollers for the support of the chain, the spindles running in bearings, having blank ends to exclude grit. The idler rollers at the end of the bucket ladder are attached to a steel shaft, which has a renewable sleeve, running in gun-metal bushed adjustable bearings. Adjustment is by screws in manganese bronze nuts for taking up slack in the chain. A removable end cap to these bearings allows renewal of the bush and sleeve without dismantling other parts. Gun-metal bushed idler rollers, revolving on a fixed steel shaft, are provided at each end of the knuckle joint, and at the junction of the lower and upper bucket ladder. The upper bucket ladder is of similar construction to the lower portion, being hinged at the top so that the bottom can be raised or lowered for parallel cutting. A guide fixed to the undercarriage serves to take up the sideways pressure on the bucket ladder.

The chain is of steel, provided with manganese steel bushes and pins, which are prevented from turning by projections on the links. A bucket is riveted and welded to every sixth pair of links, which have easily renewable wearing pads of special metal to support the chain and take the wear. The buckets are of pressed steel having forward and side cutting teeth of manganese steel easily renewable. Drainage holes are provided for excavating below water level. The drive is transmitted from the clutch pulley on the engine shaft by means of a totally enclosed belt drive to the top countershaft, the final drive to the sprocket shaft being through spur reduction gears. The bucket chain runs on two hexagonal sprockets mounted on a large diameter shaft running in gun-metal bushed bearings. Each sprocket has reversible and easily renewable manganese steel teeth and a side guide flange. The buckets discharge through the back when passing over the top sprocket into a storage hopper of approximately half a cubic yard capacity, having a door which can be left open or closed at will. In certain cases a mechanical scraper is provided to aid discharge. The wagons for the material travel with the excavator, which connects with the side of the wagon by an arm. They are, of course, hauled away when filled.

A machine of this type with a 49ft. ladder, which will dig to a depth of 35ft. and have an output of about 100 cubic yards per hour, requires 36 horse-power. It runs on a track of 7ft. gauge, and weighs some 50 tons.

Atlas Diesel Company, Ltd.

The air compressor illustrated by Fig. 38 is a new one exhibited by the Atlas Diesel Company, Ltd., of New Oxford House, Hart-street, W.C.1. Its chief peculiarity lies in the fact that the engine and compressor are built as one unit with a single crank shaft. The engine is a four-cylinder two-stroke solid injection oil engine and the compressor single-acting, with two cylinders. But the lower side of the compressor pistons are used to supply the scavenging air for the engine. The design is very simple and the number of component parts is, naturally, reduced.

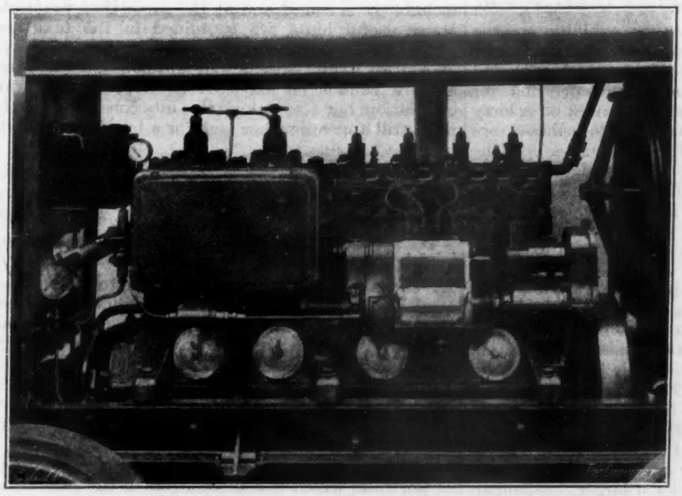

Fig. 38—Portable Air Compressor—Atlas

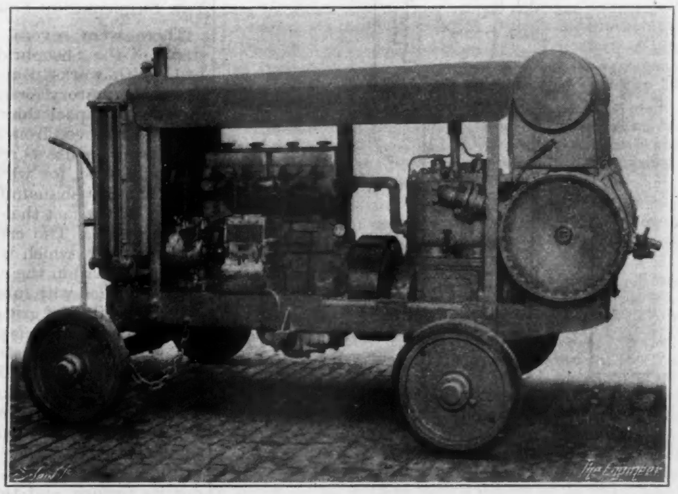

Fig. 41—Portable Air Compressor—Air Pumps

The set is fitted with forced lubrication throughout, and an automatic engine speed reduction gear so connected with the compressor unloader regulator as to follow closely all variations of the load. The small generator fitted to the engine automatically charges an accumulator for heating the starting device, and can also be used for lighting, which is a great convenience at night. Though fully enclosed, all parts are accessible for inspection; adjustments are few and simple, and the machine requires practically no attention when running. The compressor is designed for working up to 100 lb. per square inch pressure, and when running at its normal speed of 1000 r.p.m. has a piston displacement of 180 cubic feet per minute, with an indicated capacity of about 132 cubic feet free air per minute. The engine is rated for 30 B.H.P. continuously, and the fuel consumption of the set under ordinary working conditions is about 10 lb. of fuel oil per hour. The overall dimensions are approximately 8ft. 6½in. length by 4ft. 10½in. width by 5ft. 8in. height, and the net weight about 34 cwt., thus not differing appreciably from a petrol-driven machine of corresponding output.

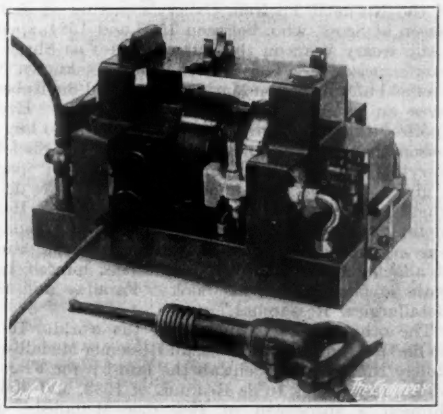

Fig. 39—Portable Electric Air Compressor—Atlas

The little air compressor shown in Fig. 39 is intended to be handled by two men. It comprises an air-cooled compressor direct coupled to an electric motor; mounted upon a rectangular air receiver, requiring a floor space of only about 2ft. by 1ft. 2in., and weighing complete only about 110 lb. It is designed for a maximum pressure of 50 lb. per square inch with a capacity of about 11½ cubic feet of free air per minute, sufficient for operating a light chipping or riveting hammer, or drill, &c., and thus could be found useful for building and erection work wherever a direct or alternating current supply was available. It is supplied with a switch, plug contact, 30ft. length of electric cable, and 50ft. length of ½in. air hose, while a light " Atlas " chipping hammer is usually included as equipment.

Air Pumps, Ltd.

There were four air compressing sets on the stand of Air Pumps, Ltd., Emerson-street, Southwark Bridge, London, S.E.1. Two were driven by heavy oil engines and two by petrol engines. We illustrate in Fig. 41 one of the former, driven by a Dorman-Ricardo engine. It has an air output of 147 cubic feet of free air per minute and a working pressure of 100 lb. per square inch. The air compressor has two cylinders, 6in. in diameter by 4½in. stroke, while the engine has four cylinders, 4in. by 5⅛in. The speed is 100 r.p.m. The air valves are spring loaded steel plates, hardened and ground all over. A larger set of the same general type, but with a capacity of 300 cubic feet per minute, was also exhibited on this stand. Another exhibit was a small air-cooled petrol-driven plant, useful for building construction, and other work where painting has to be done. It is a very compact unit, the overall dimensions being 37in. by 24in. by 37in., so that it can be transported anywhere in the building without difficulty. As both engine and compressor are air cooled, and as these sets generally work in places where low temperature exists in winter time, the user is relieved of all anxiety with regard to freezing up at night.

Petters, Ltd.

The most noteworthy exhibit on the stand of Petters, Ltd., Yeovil, was, perhaps, the new 5 and 8 H.P. Atomic Diesel engines, illustrated by Fig. 40, the constructions of which are almost identical, while they run at speeds of 750 and 650 revolutions per minute respectively. They are, it will be seen, of the vertical, single-cylinder type, and are intended for running on the lighter grades of fuel oil. The cylinder head is of very simple design, and has a detachable steel water jacket, which not only greatly facilitates cleaning of the water passages, but also tends to relieve internal stresses in the head. The combustion chamber is of the open type, the atomiser being arranged centrally in the head and completely surrounded by cooling water. Both the underside of the cylinder head and the piston crown are machined all over, thus offering the least possible resistance to scavenge air, and, at the same time, promoting good turbulence. A compression release valve is fitted for use when starting by hand, and it is worthy of note that no form of preheating device whatever is required for starting nor is a secondary combustion chamber used.

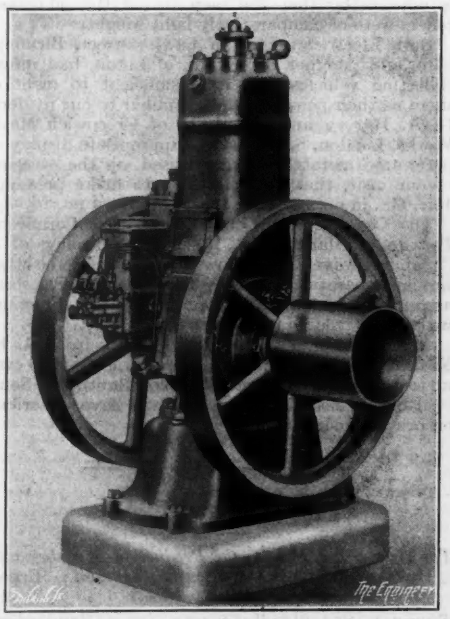

Fig. 40—5 B.H.P. "Atomic" Engine—Petters

There were on this stand some other oil engines of greater output, which have been improved by the use of ball and roller bearings, and an air-cooled engine of 4 horse-power. A contractor's set, comprising a pump capable of drawing 4000 gallons per hour against a suction head of 25ft., driven by a 2 H.P. air-cooled engine, and an air compressing set, capable of delivering 5¼ cubic feet of free air at a maximum pressure of 350 lb. per square inch, were also exhibited.

Bell Brothers (Manchester 1927), Ltd.

The stand of Bell Brothers (Manchester 1927), Ltd., of Calder Ironworks, Denton, Manchester, was devoted to the chlorination of water supplies for their sterilisation, and also their filtration. The filters were exemplified by scale models, while a chlorination plant, such as that illustrated by Fig. 42, was shown in full scale.

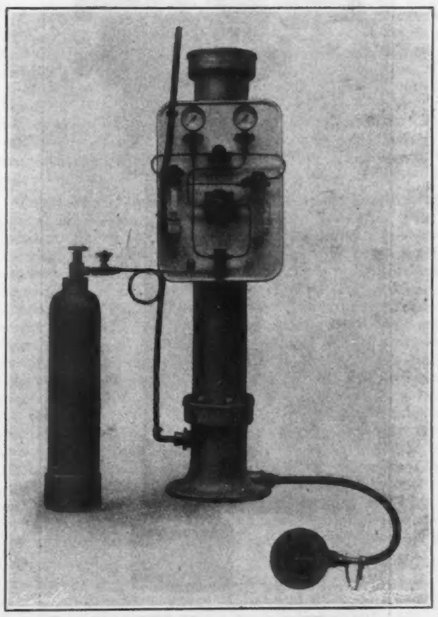

Fig. 42—Chlorination Plant—Bell

This chlorinating plant, which is also shown diagrammatically in Fig. 43, is intended for industrial services; that is to say, in those cases where a slight overdose of chlorine will not be objectionable on account of its taste, as it might be with potable water, but yet a thorough sterilisation is desired. For such purposes a gravity feed of an aqueous solution of chlorine, into the rising main, has been found most satisfactory, and the apparatus illustrated is used for this purpose.

Referring to the diagram, Fig. 43, which, it will be noticed, includes two bottles for storing the liquid chlorine, as against only one bottle in the half-tone engraving, Fig. 42. The chlorine gas evolved from the liquid in the bottles A A is controlled by the valves B B, and goes by flexible pipes to the combined junction-box and filter C, which is fitted with a pressure gauge D. The pressure of the gas is reduced by a reducing valve at E, equipped with another gauge F, to a pressure of about 1¼ lb. per square inch. Both the gauges are so arranged that their working parts are not subjected to the corrosive action of the chlorine gas. From the pressure reducer the gas is admitted through the micrometer valve G to the meter H. (An enlarged view of this meter is given in Fig. 44, while its operation is described later.) The meter gives a direct reading of the amount of chlorine passing, which can be regulated by the valve G. The gas then goes through the valve J to the absorption chamber K. This chamber is made of glazed, acid-resisting stoneware, and is supplied with a trickle of water that absorbs the chlorine. The resultant solution flows away by the pipe L to the supply which is to be sterilised. A drying apparatus is provided at M in order to inhibit the passage of any moisture from the absorption chamber to the control apparatus when the flow of gas ceases.

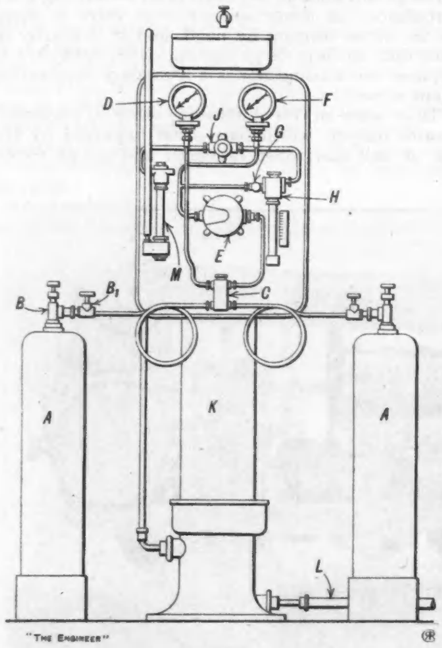

FIG. 43—DIAGRAM OF CHLORINATOR

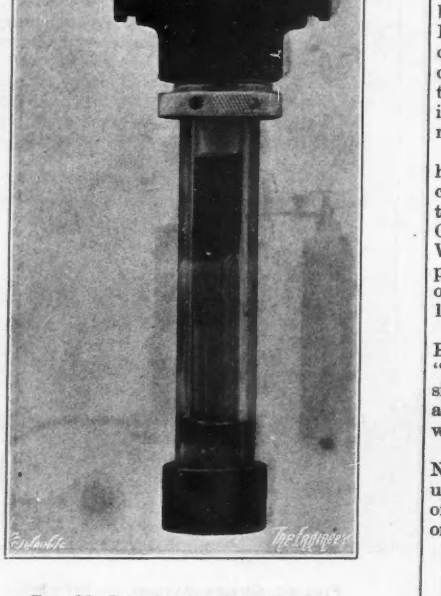

FIG. 44—PULSATING GAS METER

The meter—see Fig. 44—is of the pulsating type, and consists of two tubes placed one inside the other, the inner tube having a small syphon pipe fused inside it, as shown in the illustration. The gas passes down the outer tube and depresses the liquid therein until it reaches the bottom of the syphon, when the gas rushes through to the centre tube, the pressure is thus reduced in the outer tube and the liquid returns to its original level. The pressure then again builds up in the outer tube, forcing down the liquid, and the cycle is repeated. The number of pulsations per minute is counted and the amount of gas passing is given on a table according to the number of pulsations. The pulsating meter is capable of measuring very small volumes of gas and has a range of approximately 30 to 1. The volume of each pulsation is controlled by the syphon pipe and the capacity of the meter may be altered by inserting another centre tube with a longer or shorter syphon as may be desired.

There were also on this stand some little air compressors, designed much after the fashion of a centrifugal pump, and arranged to be directly driven by electric motors for supplying air to filter beds for aeration and agitating purposes.

THE SHEEPBRIDGE COAL AND IRON COMPANY, LTD.

There were several interesting exhibits on the stand of the Sheepbridge Coal and Iron Company, Ltd., with works near Chesterfield, which included a small gyratory crusher for surface dressing for roads, so compact that it can be mounted on a lorry and easily moved from point to point to make a store of dressing for use as required. This crusher is of the Kennedy type, for which the Sheepbridge Company holds the British manufacturing rights, and is characterised by the fact that there is only one, belt-driven, moving part. The crushing cone is mounted on a vertical shaft, which is given a rotary and excentric movement within the casing. The bearings are completely flooded with lubricant in such a way that there is no possibility of grit getting into the rubbing faces.

Another interesting product of the firm, which was, however, not demonstrated *in corpus* on the stand, but was shown by illustrations, is a machine for making concrete blocks which are truly waterproof. The essential idea is that the block or slab is made in a mould and subjected to violent vibration to consolidate it. It is then placed on the travelling table of the machine, passed under a screeding roll to level out its surface, and then under a larger "callendering" roll to squeeze and compact it. The result is a surface which is said to be absolutely impervious to water and a finish equal to that of hand-tooled stone.

SOME OTHER EXHIBITS.

Holman Brothers, of Camborne, Cornwall, had an extensive display of pneumatic machinery, both for compressing air and for utilising it for rock drills and such purposes, including compressing sets driven by both electric motors and oil engines. Dennis, of Guildford, had two gully emptiers and a refuse collector mounted on chassis of 12ft. 6in. and 9ft. 6in., of which the former has a tank divided into two compartments for 400 gallons of clean water and 300 gallons of sludge; and Fodens Ltd., of Sandbach, Cheshire, had two refuse collecting vehicles, one driven by a 46 H.P. petrol engine, and the other by a Dorman engine of 58 B.H.P.

Barford and Perkins, Ltd. (with whom, it will be remembered, are now associated Aveling and Porter, of Rochester), were showing a number of road rollers, but, with one exception, they are driven by internal combustion engines, either of the compression-ignition type, or for petrol. It is noteworthy that the majority of the oil-driven rollers were of comparatively light weight.

Both Electricars Ltd., of Lawley-street, Birmingham, and Commer Cars, Ltd., of Luton, had refuse collecting vehicles, but it is sufficient to mention them as their construction is familiar to our readers. G. A. Harvey and Co., Ltd., of Greenwich Metal Works, London, S.E.7, had an appropriate display of perforated metals, and emphasised, on the occasion of our visit, that they are able to make pressings 10ft. 6in. in diameter by 1½in. thick.

The Lea Recorder Company, Ltd., of Cornbrook Park-road, Manchester, 15, had a display of a "standing wave" water flow recorder, and some other similar apparatus, but as we hope soon to give some account of the latest developments in this direction, we will not enlarge upon the exhibits here.

Among the cranes shown were some from R. H. Neal and Co., Ltd., Ealing, ranging from 6 cwt. up to 1 ton, and some made by Thos. Smith and Sons, of Rodley, near Leeds, which we have described on previous occasions.

Literature.

The Analysis of Oil for the Production of Lubricants.
By ARTHUR A. ASHWORTH. London: Ernest Benn, Ltd. 1933. Price 9s.

THERE is undoubtedly a need for a standardised method for the analysis of crude oils and crude residua with the object of determining their lubricating oil content, but it is probable that more experimental work will have to be done before it would be safe to define a method as an international standard.

Mr. Ashworth gives a detailed description of the design of his laboratory vacuum tube still, and also full particulars of the operating procedure. The still consists of a steel pipe electrically heated, connected to a spray separating device and a condenser. The degree of vacuum is controlled by an automatic air bleed operated by a solenoid. The procedure is to take the residue of the crude oil after part of the gas oil has been removed by atmospheric steam distillation in a small capacity still. This residue is distilled through the vacuum tube still to yield a single distillate from the residue. The complete distillate is then treated for removal of naphthenic acids and subjected to acid refining, after which it is fractionated by redistillation in a vacuum capacity still. Clay treatment takes place during the latter distillation.

This is claimed to represent the most up-to-date large-scale practice, and to be preferable to methods whereby the fractionation takes place in the dephlegmator of the tube still. There is some doubt as to whether the majority of refinery technicians would agree with this claim, but there is no doubt that the procedure lends itself to laboratory scale work.

The book is very clearly and simply written; the technology is sound and at the same time practical. Many useful hints are contained in the text and greatly enhance the value of the work. The subject is, of course, highly specialised, and consequently such a work cannot be expected to have a very wide circulation, but after taking this into consideration the price still appears rather high for a book of sixty-odd pages.

The Rise of Metallurgy, with Special Reference to Sheffield Discoveries, Inventions, and Research.
By Sir ROBERT HADFIELD, Bt., F.R.S. London: Chapman and Hall, Ltd. 1933. Price 5s.

AT the September meeting of the Iron and Steel Institute in Sheffield Sir Robert Hadfield presented to all the members and visitors an address of welcome to the East Hecla works. It was a stout brochure dealing with Sheffield and its principal industries, and altogether an edition of 1000 copies was printed. Since then another edition of the same number has been published, and is available to the public, the profits on the sales going to charities.

The first edition was remarkable for the collections of portraits which it contains, but in the second the number has been increased by the reproduction of a portrait, obtained after much difficulty, of Professor W. H. Greenwood, who was the first Professor of Metallurgy, 1886–89, in Sheffield University. His successors were Dr. J. O. Arnold, 1889–1919; Dr. Desch, 1919 to 1932, and now Professor J. H. Andrews. Amongst other Sheffield educationists whose portraits are reproduced, we note the names of Mark Foster, Sir Frederick Mappin, Sir William Clegg, and Sir Henry and Colonel H. K. Stephenson.

Whilst the text of the volume deals with the ancient and modern history of Sheffield, its outstanding feature is certainly this collection of portraits, which begins with one of Cardinal Wolsey, who arrived at the Manor House in November, 1530, and soon after "left under escort on the last stage of his tragic journey." Wolsey is followed by a reproduction of the National Portrait Gallery's picture of Mary Queen of Scots, who, between 1570 and 1584, spent many weary years in the Turret House as Shrewsbury's prisoner. The Turret House is known in Sheffield now as Queen Mary's Lodge, and Sir Robert gives an exterior and interior view of it. Even Geoffrey Chaucer figures in this gallery for no larger reason than his well-known reference to a "Shefeld thwytel," and to Benjamin Huntsman a page is given. As the pioneer of crucible steel, the debt which Sheffield owes to him is incalculable. Here we find, too, a reproduction of the plaque of Faraday, who carried out that astonishing investigation of alloy steels with which Sir Robert himself has dealt so faithfully in his book "Faraday and his Metallurgical Researches."

The other portraits range over the world. Here we find a group of Americans, all Bessemer Medallists, Holley the first and Schwab the latest; for France we are taken back to de Réamur, of 1683, and down through a succession of Bessemer Medallists, all bearing world-famous names, to Charles Frémont, who received the great award in 1921. Germany, Sweden, Italy, Japan, Holland, and Russia all contribute portraits of men who have made their mark in the field of metallurgy, or the iron and steel industries. It would be quite impossible to mention all the other portraits to be found in this "album," but we must not overlook the page reproduction of an admirable painting of Sorby. Many of the men here shown are still living, and not a few of them, we suspect, would like to be as young as when they sat to the camera.

The text of the volume pays particular attention to the Iron and Steel Institute, to the interests of which Sir Robert has devoted much care, but at the same time sketches in a useful manner the rise and development of that great industry which has made Sheffield what it is to-day, and at one time placed Great Britain in the forefront of iron and steel-producing countries.

IT is reported from Dublin that a jobbing plumber in that city has recently acquired oxy-acetylene equipment, and he is the first in Dublin to do so.

Railway and Road Matters.

THERE was a collision on the morning of Thursday, November 16th, between a light engine and a passenger train at Hove, Southern Railway.

WE understand that the French "Super-Mountain" locomotive, exhibited publicly early in the year, has not yet been put into service on the Cherbourg line because it has been found necessary to carry out certain road reinforcements.

THE rolling stock renewal programme of the London, Midland and Scottish Railway provides for 2000 12-ton open wagons, with underframes constructed wholly of British steel. They will be fitted with the vacuum brake to enable them to be used in high-speed freight trains.

THE traffic receipts for the forty-fifth week show the following increases in goods receipts:—Great Western, £18,000; London, Midland and Scottish, £33,000; London and North-Eastern, £55,000; Southern, £2000. The L. and N.E.R. had an increase of £9000 also in coal receipts; under that heading the three other companies had little change.

THE tour of the "Royal Scot" in Canada and the United States came to an end on its arrival at Montreal on November 11th, which city it had left on May 1st. Additionally to its five-months' stay at the Chicago Exhibition, it has been on view at eighty places, has been inspected by over 3,000,000 people, and has travelled more than 117,000 miles under its own steam.

IN three week-end stages, commencing on Saturday, November 25th, the Southern Railway will relay the "North Kent East" Junction of the main and Greenwich lines between London Bridge and New Cross, one of the busiest spots on the Eastern Section. The week-end of December 2nd–4th will probably be the high spot of the job. It will see 200 men working hard against time.

IN seeking for sanction by the Railway Rates Tribunal for the introduction of an experimental schedule for the conveyance of livestock in the Gloucester area, it was stated that the conveyance of livestock had practically left the railway companies since the introduction of efficient motor transport specially made for the purpose, except in cases of large consignments for long-distance traffic.

THE London Passenger Transport Act has so widened the area of the London Traffic Commissioner's control that advantage was taken of the Road and Rail Traffic Bill to abolish the Southern Traffic Commissioner. There was considerable opposition to this on the ground that it would cause confusion, inconvenience, and expense, but Mr. Oliver Stanley assured the House that that was not so; moreover, there would be a saving of £3000 a year. The proposal was agreed to.

THE Road and Rail Traffic Bill received the Royal Assent before Parliament was prorogued on Friday, November 17th. One of the amendments made in the House of Lords was that a driver's statutory rest hours must be taken during a period when the man was not under the direction of his employer. Efforts had been made to get this inserted in the Bill when before the House of Commons, but the Government refused, so the acceptance of the amendment made in the Upper House gave general satisfaction.

DURING the three months ended March 31st last the assistant inspecting officers of the Railway Department of the Ministry of Transport inquired into forty-four of the more serious accidents to railway servants. There were twenty-two fatal cases, and as in one instance three men were killed, the total number of fatalities was twenty-four. Twelve accidents were considered to have been due to want of care, eight to misadventure, and one to an error of judgment. In the triple fatality the look-out was insufficient, as the ganger himself was also acting as look-out.

THE Railway Rates Tribunal has recently had to decide whether what are officially known as motor coaches—in contrast to trailer cars—used in electric traction, are, as contended by the manufacturers, "railway vehicles running on their own wheels," or, as claimed by the railway companies, "railway motor carriages with engines combined running on their own wheels." The Tribunal, on November 14th, gave judgment in favour of the latter opinion on the ground that the vehicles were primarily for the purpose of hauling or propelling a train, and not for the conveyance of passengers.

Two questions as to the electrification of railways were addressed to the Minister of Transport on November 15th. In answer to one, Mr. Stanley said that the companies had assured him that they were continuing to give consideration to that matter. He had not, however, any information with regard to any schemes of main line electrification which were likely to be proceeded with in the near future. The other question asked if the scheme for electrification in the L. and N.E.R. suburban area included the branch to Tottenham and beyond. The response was in the negative, but the whole answer is of interest in that it spoke of the schemes at present under consideration by that company "and the Standing Joint Committee set up under the London Passenger Transport Act."

THE reference, under "Sixty Years Ago" in our issue of November 3rd, to the railway "disasters" that occurred during and about October, 1873, may be supplemented by the observation that, even in these latter days of greater safety in railway travel, the term "disaster" would not be applied to any of the railway accidents that occurred at that time. Whilst there were fifteen accidents during 1873, only that of August 2nd at Wigan, which involved the death of thirteen passengers, could be described as a disaster. In eight only one life was lost in each accident, and the maximum, other than Wigan, was one where four passengers were killed. It is true that in the following year the Royal Commission on Railway Accidents was appointed, but that was not inspired by any particular accident or accidents; rather was it a concession to the then Earl de la Warr for the rejection by a Select Committee of his Regulation of Railways (Prevention of Accidents) Bill, the passage of which would have anticipated the requirements compulsorily enforced by the Act of 1889.

Notes and Memoranda.

WRITING on the subject of drilling deep holes, Mr. H. C. Bullock, in the *Machinist*, says that where a high pressure of lubricant is not available, it is advisable to encourage a slight chatter of the drill to keep the chips moving.

NEW specifications of the American Society for Testing Materials for bridges call for steel having a tensile strength of 60,000 lb. to 72,000 lb. per square inch, with a yield point of not less than 33,000 lb. The steel must be made either in the open-hearth or electric furnace.

THE telescope for the new McDonald Observatory on Mount Locke, in south-western Texas, will be built by the Warner and Swasey Company, of Cleveland. It will be the second largest in the world, and will cost approximately 325,000 dollars. The main mirror will be 80in. in diameter.

THE first 42,000-kW section of the Trebovice steam station in the Ostran-Karwin coalfield of Austria brings a new high-pressure plant into operation. It has three Loeffler boilers, each capable of providing 126,000 lb. of steam per hour at 1985 lb. per square inch and 932 deg. Fah. Two three-stage condensing turbines connected to 6300-volt alternators are used.

AN investigation has been carried out by the United States Bureau of Mines on the viscosity of natural gas, and a copy of the report thereon may be obtained from the Government Printing Office, Washington, price 5 cents. The experiments were carried out at various temperatures from 40 deg. to 80 deg. Fah. and showed that the viscosity ranged from 0·00000646 to 0·00000866 lb. per sec.-ft., depending upon the chemical composition of the gas.

THE North Bridge, Edinburgh, has been reopened for traffic after undergoing repairs which have taken six months to complete. The work, which has cost £35,000, was made necessary by rain water eating into the steel of the bridge underneath the roadway and creating a situation which, sooner or later, would have become dangerous. The old deck girders have been removed and new standard steel joists substituted, providing a beam of greater strength and rigidity, and giving a saving in weight of about 50 per cent.

Two interesting "Shorterising" (see THE ENGINEER, February 3rd, 1933) jobs have been recorded. The first was for cast iron bricks, 24in. by 3in. by 1½in. hardened to a depth of ½in. These bricks formed part of a cast iron bed or shoot where coke was discharged from the furnaces, the abrasive action of the coke wearing out the untreated parts very quickly. The second case was the "Shorterising" of cast iron rollers for plugging clay at a colliery brickworks. These rollers were originally made of steel with ½in. diagonal rib, and after two years the rib was worn flush with the bare plate. The company concerned is now having two new rollers made, 2ft. by 16in. by 1in., in cast iron and will have them "Shorterised."

MR. J. E. HAYGARTH, emphasising the importance of the use of lanolin in paint, urged that it maintained a continuous film; its viscosity was such that it did not run off easily; it had no chemical drawbacks which might cause rusting; it would emulsify and thus absorb surface moisture; it did not crack and allow rusting to occur along the cracks; it was non-drying; did not set hard, but could be hardened by the addition of up to 10 per cent. of wax, such as paraffin wax, if necessary; and it was cheap, plentiful, and British. He knew of a number of cases where it had been used as a paint on girders; in the opinion of those who had used it, it lasted very much better than ordinary paint—it had proved to be the best thing tried. Further, it had been used on ships' bottoms as a rust preventer, but appeared to have an attraction for barnacles.

A VISION of the future by Dr. F. Bergius, as he gave it to the Institution of Chemical Engineers! Having worked the wood hydrolysis process satisfactorily in large units, and having studied many different types of wood and waste wood, and solved the problem of good heat economy, we possess, said Dr. Bergius, the fundamental knowledge for reliable calculation. In countries in which wood is obtainable in large quantities, for instance, the Baltic States, Roumania, the North-West of the United States and Canada, wood sugar can be produced at a lower price than cane sugar is produced in the countries of the torrid zone. Also in England glucose can be produced at an extremely low price from imported wood. The wood sugar represents not only a cattle food, but at the same time is a source for the production of yeast as well as of glucose for human consumption. Hence the fundamental elements for human food can be procured from raw materials which Europe possesses in abundance. For the over-populated industrialised European countries, therefore, the wood hydrolysis process may become an important factor towards independence of a food supply from abroad in the same way that the coal hydrogenation process will in some degree ensure independence of a foreign oil supply.

CERTAIN American abrasive manufacturers are, according to the *Machinist*, now using an "electrocoating" process for making abrasive paper. The process, it is said, has made possible 60 per cent. increased efficiency on some jobs, while the average improvement is from 30 to 40 per cent. over the results obtained with products previously coated by sifting grain on to the fresh glue. The backing, after being coated with adhesive, passes between two plate-shaped electrodes. It is positioned nearest to the upper or positive plate with its coated side toward the negative plate. The abrasive particles are carried between the electrodes on the upper surface of an endless belt. A high-tension electrostatic field is maintained. As the particles enter the field they are electrified and caused to take a position with their long axes perpendicular to the surfaces of the two belts, parallel to lines of force in the field which distributes them in an even pattern. The action of the field then propels them toward the backing strip where they are embedded, point out, in the adhesive. As a result of this method of manufacture, the surface of the new coated abrasives presents the maximum number of cutting points to the work. The even distribution of the particles improves the quality of the work produced.

Miscellanea.

THE Pretoria, South Africa, City Council proposes to expend £350,000 on electricity extensions.

THE estimated production of benzol from the gasworks at Manchester, Liverpool, Oldham, Stretford, and Padiham is over 800,000 gallons a year.

A NEW lighthouse is to be built at Talaimannar, Ceylon, at a cost of Rs. 14,500. It is to be of cement and sand bricks and will replace an iron structure.

A PAPER factory is to be put up on the Umgeni River, Natal, for the use of sugar bagasse produced locally. The projected output of paper is 15,000 tons a year.

THE new harbour at Vizagapatam is to be formally opened by the Viceroy of India in the middle of December. It has a depth sufficient for vessels of 29ft. 6in. draught.

A NEW society has been formed under the title of the Anti-Noise League. The Chairman of this body is Lord Horder, and the offices are at 18, Old Cavendish-street, W.1.

Two of the six Southampton flying boats ordered by the Turkish Government have left the Supermarine Aviation Works (Vickers), Ltd., Woolston, Southampton.

A NEW coal pit has just been sunk, to a depth of 750ft., on the bank of the river Blyth, Northumberland, by the Cowpen Coal Company, and is intended to produce 3000 tons of coal a day.

THE new road bridge over the river Teesta, on the way from India to Sikkim and Tibet, was opened on October 26th. It is a reinforced concrete arch of 300ft. span and is the first of its size in India.

EXPERIMENTS are being made in South Wales in the use of oxy-hydrogen and oxy-coal-gas processes for the melting of lead in hydraulic presses used for the manufacture of lead-covered cable.

THE headquarters of the American Society for Testing Materials are being moved to more commodious offices at Atlantic Building, 260 S, Broad-street (N.W. Corner, Broad and Spruce Streets), Philadelphia.

THE bore-hole which is being put down on the Rand by West Witwatersrand Areas, Ltd., has arrived at a depth of over 2500ft., and a recent survey has shown that its deflection from the vertical is only 4 deg. at the bottom.

IT is proposed to build a new bridge across the Gorai River near Kustia Station, on the Poradaha-Goalundo section of the Eastern Bengal Railway. It will replace a bridge built by Sir Bradford Leslie in 1869 and will have four spans of 350ft.

A SYNDICATE of Liverpool business men, it is announced, has been formed to erect what will be the largest exhibition hall in Britain. The cost will be in the neighbourhood of £450,000. The Liverpool Corporation has offered a 33-acre site on the new East Lancashire Road.

A RECORD is claimed by John Lysaght's Normanby Park Steel Works, Scunthorpe, Lincolnshire, where, one night during October, there were rolled 433 tons of material in an eight-hour shift. During one week in the month the works rolled 5121 tons of steel, also a record.

THE Birmingham section of the British Industries Fair, which is to be opened at Castle Bromwich on February 19th, is to be divided up into four sections for engineering, metals, quarry, roads and mining, and transport. Each is to have its separate entrance and car park, but the whole Fair will, of course, be free to any visitor.

A COMPLETE train is to be equipped as an exhibition of British goods and will commence a tour of the southern half of England, following the British Industries Fair. A similar train will tour the North later and plans are being made for tours on the Continent and in the Dominions. The first train will be composed of seventeen coaches and will be adapted to house about a hundred exhibits. There will be a reception room, a dining car, and a coach carrying the electric lighting and power plant. The train will leave Birmingham on March 14th.

THE fiftieth anniversary of the world's first machine-propelled submarine may be celebrated this year in Sweden. After many unsuccessful attempts to construct submarines in different countries, a prominent Swedish engineer and arms manufacturer, Thorsten Nordenfelt, succeeded in building the first real submarine, which was launched in the Maelar Lake near Stockholm in the late summer of 1883. Mr. Nordenfelt, who owned large armament works in England and was one of the most important military inventors and constructors of that time, built a submarine that was 64ft. long, 9ft. wide, and had a displacement of 60 tons. It could be submerged 50ft. below the surface, was propelled by a 100 H.P. compound steam engine, and moved with a speed of 4 knots under water. It carried an outside torpedo, that could be launched by a mechanical contrivance, had a crew of three men, and could keep below the water for six hours. Instead of a periscope it had a small glass cupola, large enough for the captain's head. The first submarine was sold to Greece. The following year Turkey and Russia ordered two each.

DISCUSSING the question of "What is needed to make the low-temperature carbonisation of coal a national industry," at the meeting of the Institute of Fuel, held at St. Ermin's Hotel, on Tuesday, November 14th, Mr. John Roberts expressed the view that direct State aid was unnecessary, but the moral support of the Government would be a great help. He considered that a carbonising corporation should be formed, having sufficient financial backing to erect plants in every coalfield, of such type and size as to be suitable for the coals available and the proximity of the market. Under such a scheme the plants to be erected should be selected by a committee of technical experts, including one representative of the Fuel Research Board and one from the Coalowners' Association. The corporation should have a central publicity department and sales organisation, together with a research department under its own control. It should keep a close watch on new developments at home and abroad, in the treatment of coal and its derivatives, and any process warranting trial should be thoroughly tested.

LARGER CRUISERS.

An announcement of considerable moment in its bearing on naval policy was made by the First Lord of the Admiralty in Parliament last week. It had reference to the cruiser programme for the current year, which, as voted in March, made provision for one "Leander" class ship of 7250 tons and three "Arethusas" of 5400 tons, armed with eight and six 6in. guns respectively. Had this programme been completed in its original form, it would have given us eventually nine "Leanders" and five "Arethusas," authorised in the period 1929–33, the aggregate being 92,250 tons; though, in fact, the slightly lower displacement of the earlier "Leanders" would have reduced the actual total to about 90,000. In ordinary circumstances these fourteen ships would have represented a valuable reinforcement to the Navy, which is urgently in need of more cruisers. But, however good a warship may be in itself, and the "Leander" class at any rate appears to be an excellent design, its true value can be judged only by comparing it with contemporary vessels of other navies. When that test is applied, neither the "Leander" nor the "Arethusa" can be considered satisfactory. Their displacements are respectively 30 and 50 per cent. lower than those of the largest foreign cruisers now on the stocks and their armament is proportionately inferior. The "Leander" is smaller and feebler than any foreign cruiser, excepting those building in Italy, while the "Arethusa" is a veritable minnow among the tritons. Neither class, therefore, can be regarded as a good investment. Up to now we have been building only second-rates—to adopt the ancient terminology—while every other naval Power has been launching first-rates. This is so radical a departure from traditional policy that it calls for explanation.

The reason was clearly stated by the First Lord last week. "The policy of building cruisers of comparatively small tonnage had been adopted in the hope that other nations would follow our lead. Also it will be recalled that in July, 1932, the United Kingdom delegation at Geneva put forward proposals for the reduction of future cruisers to 7000 tons, with a maximum gun calibre of 6·1in., in the hope that these would be generally accepted. Unfortunately, neither of these hopes has been realised." He went on to give specific instances of the manner in which foreign Powers were forcing up the tonnage and armament of the cruiser type. Japan has legislated for six ships of 8500 tons, reported to mount fifteen 6in. guns; the United States has gone one better by ordering four ships of 10,000 tons, also with fifteen 6in. guns, and at the same time pushing forward with the construction of several 10,000-ton cruisers armed with nine 8in. guns. To these examples might be added that of France, who has just launched the cruiser "La Galissonnière," the first of a group of six ships displacing about 8000 tons and mounting nine 6in. guns in triple turrets. Compared with all these powerful ships, the "Leander" and the "Arethusa" cut a singularly unimpressive figure. While it is the devout hope of every sane being that none of the vessels mentioned will ever have to fire a shot in anger, the fact remains that warships are designed with a view to certain contingencies, and for that reason must bear some relation in weight and hitting power to possible antagonists. Quite apart from the purely military aspect, there is the question of prestige to be considered. The spectacle of diminutive British cruisers alongside vastly superior ships of other nations is one that has become too common in certain harbours overseas, and the effect is not beneficial to this country. The assurance implicit in the first Lord's statement that the policy of deliberately building cruisers of inferior type is to cease will be hailed with satisfaction by all who have the national interest at heart. Unfortunately, some time must elapse before the consequences of our well-meaning, but, as is now avowed, futile attempt to bring about universal naval limitation by unilateral action can be rectified. That mysterious clause in the London Naval Treaty, binding us, alone among the signatory Powers, not to complete more than 91,000 tons of new cruisers by the end of 1936, has placed the Admiralty "on the horns of a very serious dilemma," to quote the First Lord's own words. Our quantum of tonnage is so restricted that it was impossible to re-design all four cruisers of the current programme on a 9000-ton basis without exceeding the allowance. The number had therefore to be reduced to three, and even then one must be of the diminutive "Arethusa" class. We believe, however, that the Admiralty's decision will command wide approval. It is true that numerical strength in cruisers is desirable, having regard to the extraordinary length of the Empire's trade routes, which literally girdle the globe. On the other hand, it would be the negation of wisdom to continue building ships which were definitely inferior in fighting power to any possible commerce raider. At least twice during the Great War valuable convoys were cut to pieces after their naval escort had been overwhelmed by stronger enemy ships; while the fate of the "Pegasus" at Zanzibar and of the "Good Hope" and "Monmouth" at Coronel should warn us never again to match inferior ships against opponents of heavier metal. Much as the action of foreign Powers in building large cruisers is to be deprecated from the point of view of disarmament, at least it has had the advantage of dispelling some of the illusions which have hitherto made a muddle of our defence policy. It is no longer possible to doubt that in cutting down our armed forces we have given encouragement to other Powers to expand their navies and air fleets. Command of the sea, even though it be only local, is such a tempting prize that no country is to be blamed for trying to grasp it. If Great Britain is finding the trident too heavy, others will be only too ready to relieve her of the burden. It should, however, be clearly understood that without adequate national defences we should have no voice in the direction of world affairs, and our influence, which is wholly on the side of peace, would cease to carry weight. These are considerations to which we invite the earnest attention of our disarmament zealots. Not for a moment do we credit the United States or Japan or France with warlike intentions, yet the fact remains that one and all are energetically developing their naval and air forces. They are obviously doing so with the idea, not of attacking their neighbours, but of rendering themselves more secure against attack, knowing security to be the most potent deterrent to war.

The decision to build two large cruisers and a small one in place of one medium and three small vessels involves no increase in the aggregate tonnage of the 1933 programme, which remains approximately at 23,400. Nor will there be any increase in the original estimate of cost; on the contrary, a slight reduction is anticipated. Particulars of the new class of 9000-ton cruisers will be awaited with interest. That the design will present features novel to the British Navy seems certain. We assume that naval officers will not be satisfied with less than twelve 6in. guns, which would be quite a moderate armament for ships of this tonnage, and in that case the adoption of triple mountings would appear to be unavoidable. Admittedly there are drawbacks to the triple turret, especially in the case of quick-firing guns, but they are probably outweighed by the advantages in respect of economy in space and weight. The three-gun turret for 6in. weapons has already been accepted by the United States, French, and German navies, and it is evident that Japan has adopted the same system in her new 8500-ton cruisers, which are, so it is reported, to carry fifteen 6in. guns. Our new cruisers promise to be enlarged versions of the "Leander" class, with a pair of triple turrets forward and aft. This arrangement ought to leave a reasonable margin for armour protection, provided the designers are content with a speed of, say, 31 knots. No case has yet been made out for a higher speed than this, and it is noteworthy that all the latest foreign cruisers are slower than their predecessors. It is to be hoped that the cruisers of next year's programme will also be of substantial tonnage. Any ships authorised then will not be subject to the limiting clause in the London Treaty, and this new freedom will afford Great Britain an opportunity of demonstrating to the world her resolve to maintain to the full that measure of naval power which has been left to her by a series of one-sided, and, in our view, inequitable covenants.

Superheated Steam in Locomotive Service.

When dealing with the first of the new "Pacific" type locomotives recently built at Crewe for passenger traffic on the London, Midland and Scottish Railway we had occasion to comment on the proportions of the superheater, and the effect of superheated steam on the water and fuel consumption. This engine, as we pointed out, follows in general design the practice of the Great Western, which is, of course, not surprising, in view of its designer's long association with that line and the successful locomotive types which have emanated from the Swindon works. There has, however, always been a distinctive difference between Swindon practice in the matter of superheater proportions and in the steam temperatures employed and that obtaining on other lines, including that for which Mr. Stanier's engine was designed, and this fact would appear to have caused a certain amount of discussion on the relative merits of what may be termed high and low superheat temperatures. This, however, by no means opens up a new question, and, judging from the working results obtained with steam carrying a high degree of superheat compared with that less highly superheated, it would certainly seem that the advantage lies with the former.

When the superheater came into general use, now some twenty years ago, it was very soon shown to produce very startling results in the matter of fuel economies, and in this country the paper on this subject contributed by Sir Henry Fowler to the "Proceedings" of the Institution of Civil Engineers in 1914 clearly indicated the gains accruing from the use of the Schmidt type of flue tube superheater. We do not propose to refer to this paper in detail, but following upon some remarks we made in our impression of July 21st, relative to certain locomotives formerly built at Crewe, we quote some figures given by the late C. J. Bowen Cooke, who stated during the discussion on Sir Henry's paper that with 357 tons at 60·5 miles per hour the consumption of coal with one of his superheated engines on a run from Crewe to Euston was 39·6 lb. per mile. We now quote the same speaker on a previous occasion when the working results with the Whale "Precursor" class were given. These engines were stated to burn on an average 57·53 lb. per mile, when hauling express trains of about the same weight at slightly lower speeds and working between the same points. The significance of these figures lies largely in the fact that the two engine types compared were, for all practical purposes, exactly alike, for it will be recalled that Bowen Cooke's four-coupled engines were in reality superheated "Precursors," having 20½in. as against 19in. cylinders. Probably the most elaborate series of tests made to establish the advantages to be obtained from the use of superheated steam were those carried out on the testing plant at Altoona. They were made with the deliberate intention of determining the relative values of different degrees of superheat. The engine employed was of the "Pacific" type, and a large number of trials were run at a definite speed and at various cut-offs, while, in order to show the effect of superheat alone on performance, the boiler was successively fitted with flue tube superheaters of different sizes, so that the amount of superheat could be varied independently of the rate of working. A study of the results is of interest. In general, it is shown that at any given cut-off an increase in superheat decreases the steam rate, and that for a given steam pressure an increase in superheat increases both the heat available and the heat utilised per pound of steam supplied to the cylinders. From these tests it seems that when using steam at 200 lb. gauge pressure and superheated 214 deg. Fah. the cylinder efficiency at 25 per cent. cut-off is 70 per cent., and the corresponding water rate 16·1 lb. per I.H.P.-hour, while at the same speed and cut-off. but with 115 deg. superheat, the cylinder efficiency is reduced to 62 per cent., the water per I.H.P.-hour being increased to 19·6 lb. A further point of interest also shown is that an increase in the superheat at a given rate of cut-off does not adversely affect the boiler efficiency; in other words, although an increase in superheat means for a given boiler an increase in the size of the superheater, the actual percentage of the heat in the coal fired which is given, each pound of steam remains substantially equal. It seems that on balance, although the heat transfer across the superheating surfaces is materially less per square foot than across the water heating surfaces, the boiler efficiency is equalised on account of the lower coal consumption for any given engine conditions or power output, which, of course, improves the furnace efficiency. Yet another point to be noted is the heat in the exhaust. Naturally, an increase in initial steam temperature means that for any given rate of expansion there will tend to be a greater temperature in the steam as exhausted. This condition is a source of loss, and can only be recovered in part by a feed heater. On the other hand, however, it would not appear proper to level this as a charge against the use of highly superheated steam, for although there can be, and frequently is, superheat present in the exhaust, and hence a high heat content per pound of steam exhausted, yet the total heat wasted in this manner may be, and in fact is, relatively low on account of the reduction in the weight of steam supplied to the engines per unit of power developed.

A study of the performance of the locomotive as a whole, when operating with steam having different degrees of superheat, reveals numerous other points of interest, not the least of which is the fact that as the superheat is increased, the steam and fuel consumptions when compared with the power developed become more constant—that is to say, curves drawn through the plotted points depicting the coal and water rates are relatively flat, showing a smaller rate of increase between the limits of maximum and minimum powers than do those for a less superheat, which tend to assimilate such curves drawn for a locomotive using saturated steam, which rise rapidly as the cut-off is lengthened, and the rate of power output increased. Judging from the experimental data on this subject so far available, results point to the desirability of combining high superheat with short cut-offs, if minimum fuel rates are to be realised, but the economic limit does not appear to have been determined.

Heat Liberation and Transmission in Boilers

THE INSTITUTION OF MECHANICAL ENGINEERS.

ON Friday evening of last week, Messrs. E. W. Robey and W. F. Harlow presented before the Institution of Mechanical Engineers a paper entitled "Heat Liberation and Transmission in Large Steam Generating Plants." Elsewhere in this issue we reprint in a slightly abridged form the first portion of the paper dealing with the liberation of heat in steam generators. The second portion dealing with the heat transmission aspects will be reprinted in a succeeding issue. Neither the manner in which it was summarised by Mr. Robey nor the trend of the discussion which ensued did the paper full justice. Mr. Robey rapidly read selected extracts from it without intercalating a single word to cover the many and important passages which were omitted. Even to one who came to the meeting fully prepared by a previous study of the paper this process of presentation proved highly confusing. To others who had not so prepared themselves there was some evidence that it resulted in their being misled as to the real contents of the paper and the authors' opinions and findings. The discussion, following the process of decimation to which the paper was subjected by its own authors, maintained on the average a low level.

Major W. Gregson, M.Sc., said that steam was still the dominant method of obtaining power, and that therefore any improvement in steam-raising technique must react favourably on industry in its widest sense. From the title of the paper the authors had attempted to cover a very wide field. Hence, in view of their space limitations, it was unfair to expect them to have enlarged on a number of the points mentioned, many of which were certainly of a controversial nature. The authors, in dealing with the important question of heat release per unit of furnace volume, stated that the size and rating of a combustion chamber was a function of secondary air admission and of the mixing of the air and the combustible substance. They appeared to view secondary air admission as a recently developed idea, which was surely not correct. Again, they were not clear as to the *method* of mixing—an all-important function. Should excessive turbulence be aimed at ? He, the speaker, considered that turbulence brought about by excessive centrifugal action was wrong, as the tendency at higher speeds was diametrically to oppose true intermingling of the particles. The centrifugal action set up caused differential sorting according to densities on the lines of the centrifugal separator. That fact probably explained why the efficiency of an oil burner fell off so quickly at ratings above its normal output; that was to say, when centrifugal action tended to separate out air and oil vapour particles. The ideal way to get intimate mixing was by diffusion, and the authors' reference to the Hammond system, where perfect diffusion was sought, presumably showed that they were thinking on those lines.

As a humble disciple of the teachings of Professor Osborne Reynolds and Dr. Nicholson, he could not subscribe to the authors' statement that little attention had been paid until quite recently by practical engineers to the application of high gas velocities to boiler design. He could refer to generic types of boilers which were the result of the logical development of the high gas velocity principle and which were well established in industry. He fully agreed with the authors when they stated that the amount of heating surface was no criterion of boiler capacity, but that the manner in which it was arranged was what really mattered. That fact was best exemplified by the high gas velocity type of boiler, in which the heating surface relation—cross-sectional area to length of gas passage—was entirely different from that appertaining to low draught boilers. To adopt high gas velocities in a boiler fundamentally designed for low speeds was, of course, asking for trouble; the surface could not properly take advantage of the higher speeds and extra molecular activity, due to speeds above the critical velocity. All that would happen in that case would be excessive draught on the fire, high back-end temperatures, and lowered efficiency. With high velocities coupled with a suitable arrangement of heating surface higher heat transmission was obtained owing to intimate molecular contact.

Continuing, the speaker showed a slide demonstrating the heat transmission from a single smoke tube set in a compartmented box, an experiment which, he said, showed conclusively the high extraction efficiency due to a velocity corresponding to approximately 4in. draught loss through the tube and also the uselessness of adding to heating surface beyond the economic figure; that was to say, when the heat transmission curve flattened out. The whole idea of specifying boiler duties by heating surfaces was, he maintained, an utter fallacy, and often resulted in completely redundant heating surface being supplied. It placed good boiler design on a level with bad practice when schemes were being compared. The output of the heating surface of a boiler depended firstly on the correct arrangement for the gas velocity adopted and secondly on the ability of the actual surface to absorb the heat. The latter factor turned entirely on clearing the steam away from the heated surface as soon as it was formed and replacing it by solid water; in other words, the heat-absorbing capacity was a function of the circulation. A boiler with good circulation could be safely run at high ratings, whereas a boiler with poor or indefinite circulation ran grave risks of overheating if it were run at anything beyond low transmissions.

Finally, he commented on the authors' method of computing economic gas velocities. His own system, he said, whenever steam-driven induced draught fans could be applied, was to take the steam at the fan prime mover equivalent to that required for preheating the boiler feed from hot-well temperature to, say, 185 deg. Fah. and calculate back the permissible fan duty to suit; that was to say, so that all the fan steam was returned to the boiler as hot feed, with consequently no debit for the service. The rule worked admirably in practice and avoided complications.

Professor G. V. Lomonossoff said that as an old locomotive engineer he had read the paper with great satisfaction, for he found in it evidence to the effect that locomotive boiler practice, previously scoffed at as unscientific and conservative by stationary plant engineers, was now being followed by those self-same critics. Intense forced draught, all-metal water-cooled walls, thick coal beds, and the use of secondary air were all characteristic of the locomotive and had been since Stephenson's time. He then proceeded to compare the authors' results with those which he had obtained from experiments on locomotive boilers. He had found that with some fuels, especially soft coals, secondary air gave very good results, but that with anthracite and oil, steam acted better than air when delivered above the fuel bed. Dealing with the theory of heat transmission, he said that in the general formula $K=C_1V^n$ for the rate of heat transfer K in terms of the mass-velocity V, the value of n had been taken by different authorities, including himself, at from 0·5 to 0·8. In reality, a straight line formula of the type $K=K_0+C\,V$ fitted the results of his own tests much better than any exponential form. He had been very doubtful, too, of the accuracy of the formala, namely, $\Delta=C_2V^2T$ adopted by the authors for the draught loss, for, according to his own experiments, the mean absolute temperature T of the gases was a function of the mass-velocity V, namely $T=T_0+a\sqrt{V}$. Combining that expression with the authors' formula, one obtained the expression $\Delta=A\,V^2+B\,V^{5/2}$, whereas his own formula had been $\Delta=A^1V+B^1V^{5/2}$. For wood and oil as fuel, he found that the coefficient A^1 was almost zero, and therefore in these cases his own and the authors' formulæ practically coincided. During the previous few days he had re-examined his results, and had to admit that, except in the case of anthracite, the authors' formula gave better coincidence with the experimental figures than his own. Continuing, he remarked that he could not agree with the authors' statement that the laws governing the transfer of heat by radiation in boiler furnaces were more obscure than those governing transference by convection. In his opinion the theory of radiation, owing to the success of the quantum theory, was now much clearer than that of convection. In Germany, in the light shed by the fuller knowledge now available concerning transmission of radiant heat, basic changes had been introduced in the design of metallurgical furnaces.

Among others who took part in the discussion was Major S. J. Thompson, who told the meeting that about ten years ago his firm had started to make stokers for the boilers which they produced, because of the troubles which they encountered in the stokers supplied to them from outside sources. He had to confess that they were still encountering troubles. The truth was that a stoker could be designed and arranged to burn perfectly one particular type of coal, but not to deal equally satisfactorily with all types which it might be desirable or economical to burn on it at different times. There was no doubt that the development in the use of powdered fuel had been responsible for the recent improvements made in the design of stokers. Stoker design had slipped into a rut from which the rivalry of powdered fuel had forced it to emerge.

Mr. Parry dealt chiefly with soot blowing and the corrosion of air heaters. He maintained that there was no mystery about dew point temperatures. The dew point could be calculated exactly from a knowledge of the composition of the gases. The process of re-circulation of the air adopted by the authors to overcome corrosion troubles was, he maintained, not a preventative, but a palliative.

Mr. Weber asked whether the after-burning in flue gases at low temperatures was to be ascribed to the combustion of gases, or of solid particles of fuel. Presumably, he said, it was the result of the combustion of solid particles, because it was stated that it was not found in the flues of oil-fired plants.

Mr. B. Samuels said that not long ago he was blamed for using 20 per cent. of secondary air. To-day, the authors invited him to use as much as 50 per cent. He maintained that as much of the air required for combustion as possible should be introduced through the fuel bed in order that it might become intimately mixed with the combustible substances.

In the course of a brief reply to the discussion, Mr. Robey dealt with the possibility of using as much as 40 per cent. of secondary air. With present designs of chain grate water-tube boilers it was perhaps quite correct to say, as some of the speakers had stated, that it was not possible or desirable to use more than 30 per cent. That figure, however, represented the secondary air admitted as such. Adventitiously admitted air, Mr. Robey maintained, would bring the real amount of secondary air up to 40 per cent. In Lancashire boilers more than 40 per cent. of secondary air had been used, and it was noteworthy that as the percentage was increased, the CO_2 content of the flue gases rose. Dealing with the question raised concerning the cause of after-combustion in the flue gases, he said that it was undoubtedly due to the burning of particles of carbon and of gases previously not consumed.

The Sulzer Single-Tube Steam Generator.*

By Professor A. STODOLA, Zurich.

No. II.

(Concluded from page 500, November 17th.)

Testing the Regulation.

In order to carry out thorough tests on the regulation of the boiler described in our last issue, it was equipped with the following measuring devices :—

(1) Temperature and pressure measuring apparatus at nine points of the tube.

(2) Recording thermometers before the injection point and at the steam outlet.

(3) Continuous recording indicators at the same points as (2).

(4) Continuous recording indicator for measuring the regulating oil pressure of the two thermostats, either of which could be connected to the instrument at will.

(5) In addition to the measurements with these devices, direct readings were taken of the position of the servo-motor pistons for injection and feed-water regulation and for the by-pass valve.

In order to imitate the behaviour of a boiler which is working under the influence of the centrifugal governor of a turbine, sudden changes in load were caused by extinguishing or lighting two oil burners, which were capable of raising together 4 tons of steam per hour, and at the same time temporarily setting the feed-water delivery by hand, leaving the final adjustment to the regulating apparatus.

In the greater number of tests, the coal firing on the grate was adjusted to generate as nearly as possible a constant amount of 3·5 to 4 tons of steam per hour, and then the rate of evaporation was suddenly increased to 7·5 tons per hour by bringing the two oil burners into operation ; the rate of steam raising was thus nearly doubled. Extinguishing the two burners again reduced the rate of generation suddenly to about one-half.

The necessity of retaining the coal firing for generating a base load, adversely affected the smoothness of the curves obtained, since the state of equilibrium was disturbed, first of all by the coal heaped on the stoker from the underfeed coal passage, and also by the gradual formation of clinker at the more or less burnt out "holes" on the grate.

The steam turbine of the works was stopped during these trials, and the whole quantity of steam was led through the by-pass valve into the low-pressure steam transformer already mentioned.

By a simple adjustment of cocks the regulating device could be used as shown in Fig. 12 or in Fig. 13. We discuss first of all the curves which were obtained with the latter.

A. *The end thermostat acts on the injection regulator (with isothermal compensating motion) ; the intermediate thermostat acts on the differential regulator and together with this on the feed-water regulator (also with isothermal compensating motion), as per arrangement Fig. 13. The pressure regulation is in operation.*

(1) *Reducing the rate of steam raising from 7·6 tons per ton to 4·3 tons per hour, i.e.* from 100 to 57 per cent. by shutting down two oil burners and at the same time temporarily setting the feed-water delivery to 4·6 tons per hour, leaving the final adjustment to the regulating devices—see Fig. 15. In order to obtain a more complete idea of the circumstances, we follow the course of these curves separately, while the curves referred to below speak for themselves. On the temperature curve of the intermediate thermostat it will be noted that shutting down the two burners, as was to be expected, makes itself manifest by a sharp drop in temperature from 370 deg. to 330 deg. Cent., *i.e.*, by 40 deg. Cent. The consequent reduction of the feed-water delivery to 3·8 tons per hour causes the intermediate temperature to rise immediately, but, because of the delayed arrival within the evaporating zone, this rise in temperature lags about 2 min. behind the minimum quantity of feed water delivered and finally reaches 400 deg. Cent. The regulating operation is then repeated with diminishing fluctuations, and the state of equilibrium, both as regards temperature and quantity of water delivered, is reached after about 15 min.

At the superheater outlet the temperature falls with slight fluctuations in the course of about 6 min. from 400 deg. to 381 deg. Cent., *i.e.*, by 19 deg. Cent., and then recovers particularly slowly, showing that the oil brake of the injection regulator was evidently too effective, and a period estimated at about 40 min. was required for a complete recovery. This was also apparent from the still incompleted movement of the injection servo-motor piston, *i.e.*, of the injection needle.

In the other curves attention should be called to the excellent agreement between the intermediate temperature read directly by thermo-couples (curve t_z) and the pressure curve of the regulating oil coming from the intermediate thermostat (curve p_I) ; the latter is an indirect measure of the former. This proves that the thermostat follows the steam temperature almost instantaneously, and that its control gear reproduces very accurately in the pressure curve the expansion corresponding to the changes in temperature that occur.

The diagram of pressure fluctuation of the regulating oil at the intermediate thermostat, given in Fig. 16, shows, in agreement with the other curves, the characteristic course of "damped oscillations." The thickness of the curves is conditioned by the action of the pulsator, which causes the indicator piston to make small fluctuations, the harmonic curves of which, however, run together into a thick line, because of the very short wave lengths.

Finally, the pressure curves marked $d\,t/d\,z$ of the additional regulating oil controlled by the differential regulator, which should have amplitudes proportionally equal to this differential quotient, show that this stipulation is also well complied with. The functioning of the separate elements of the regulating arrangement is thus proved to be excellent. During further tests with reduction in load on the boiler, and still slighter changes in temperature, falls of 8½ deg. Cent. could be observed.

(2) *Increasing the load on the boiler from 4·4 tons per hour to 7·0 tons per hour,* i.e., *from 63 to 100 per cent., by suddenly starting up two oil burners and temporarily setting the feed-water delivery by hand to 6·5 tons per hour.* From the curves in Fig. 17 it can be seen that the excessive increase in the firing causes at first a rise of temperature at the intermediate thermostat, which, through the regulation, increases the quantity of feed water delivered. This causes a fall of temperature, which, however, occurs about 1¼ min. later, so that the feed-water delivery and the temperature phase differ by about 180 deg. The lag is smaller than it was when the load on the boiler was reduced, since the increased speed of the feed water causes the water to remain for a shorter time in the tube. Taken absolutely, the lag is actually smaller than the time required for passing through the preheating zone, but greater than the time for passing only through the evaporating zone.

---

* Translated and abridged.

Although the intermediate temperature shows variations of +34 deg. and −22 deg. Cent. above and below the initial value, the maximum fluctuation at the superheater outlet is +15 deg. Cent., according to Fig. 18.

FIG. 20—PRESSURE FLUCTUATION OF REGULATING OIL FROM THERMOSTAT AT END OF TUBE

(p_{II}—According to temperature scale) At A—Change in load.

The curve of temperatures at the superheater outlet is to a certain extent a copy of the curve of intermediate temperatures. It shows that the differential and feed-water regulators have nearly succeeded in completing their tasks. It would be useful to investigate whether this favourable result is due to the appropriate quantity of feed water originally delivered.

B. *The intermediate thermostat is put in operation ; a thermostat at the end operates the injection regulator directly (with positive compensating motion), and the differential regulator ; in connection with the latter it also acts on the feed-water regulator (with isothermal compensating motion). See Fig.* 12 (ante). *The pressure regulation is in operation.*

(3) *Increasing the steaming rate from 4·4 to 7·0 tons per hour by suddenly putting two oil burners into operation and temporarily adjusting the feed-water delivery by hand to 7·3 tons per hour.*

Curves 19 and Fig. 20 show that the fluctuations of temperature before the injection point amounted to about +30 deg. and − 20 deg. Cent., and those of the final temperature to −24 deg. and +16 deg. Cent. These deviations are consequently more considerable than in the case of the arrangement shown in Fig. 13, but may be permitted in practice without any hesitation.

(4) *Reducing the rate of steam raising from* 7·1 *to* 4·4 *tons per hour by suddenly shutting down two oil burners and temporarily adjusting the feed-water delivery to* 4·6 *tons per hour.*

According to curve 21, no absolutely steady state existed at the beginning, and it cannot be said whether the comparatively very slight temperature fluctuations are partly conditioned by this fact. For the point before the injection they amount to −10 deg. and +8 deg. Cent., and for the superheater outlet to −17 deg. Cent.

(5) *Gradually increasing loading. Passing from* 4·1 *to* 7·6 *tons per hour in four steps within* 6 *min., the intensity of the firing being correspondingly increased in equally large stages.*—Expressed as a percentage of the maximum output, *i.e.*, 7·6 tons per hour, this means a total increase in the rate of steam raising of 46 per cent. in steps, each of 11·5 per cent., in a total time of 6 min.; such increases in load would not often occur in practice. According to Fig. 22, the maximum fluctuation of the temperature at the injection point is 34 deg. Cent., and at the superheater outlet 27 deg. Cent., with a very uniform fluctuation curve. The test with decreasing loading could therefore at once be started.

(6) *Gradually decreasing loading. Passing from* 7·2 *to* 4·2 *tons per hour in four steps within* 6 *min., the intensity of the firing being correspondingly reduced in equally large stages.*—According to Fig. 23, the temperature remained practically unchanged at the injection point. At the superheater outlet the variation from the initial value amounted to −20 deg. and +7 deg. Cent., which are practically very satisfactory figures.

In tests 3 to 6 the effectiveness of the differential regulator, with regard to the regulating pressure produced by it, was not clearly perceptible. The fluctuations of all servo-motor pistons caused by the vibrator are evidently very favourable in preventing any seizing, but, on the other hand, greatly affect the run of curves of regulating parts which are subject to slight pressures.

C.—Regulating tests with the pressure regulation on the boiler out of operation, i.e., *the regulating group shown in Fig.* 10 *being ineffective ; the arrangement used being that shown in Fig.* 13.

At 100 atm. pressure and full load the extremely small water content of the boiler, including the mixture of steam and water in the evaporating zone, may be estimated at 760 kilos. It might therefore be justifiable to fear that if the boiler were connected direct to the point of use the contents could "boil over" if there was a sudden and heavy demand for more steam, and the tube would be liable to become red hot, since there would then be practically no water in it.

For the same reason one might be inclined to think that it would be absolutely impossible to connect the boiler direct to a turbine equipped with its own regulation. It appeared, therefore, advisable to carry out

tests to see how much steam could be taken suddenly from the single-tube boiler while the steam pressure was, at the same time, falling. It may be said in anticipation that the results show that there is nothing to be feared in this respect.

The case where the boiler is directly subject to the control of a centrifugal governor was imitated by forcing open the by-pass valve at a certain moment, in order to allow a large quantity of steam (possibly the maximum quantity) to flow off. Naturally, the feed water delivery and the intensity of firing had at the same moment to be suited to the new demand for steam, just as they would have been by the self-regulation of the power set consisting of turbine and boiler.

The observations already mentioned in section A showed that it might be advantageous to adjust the oil brake on the isothermal injection regulator to act somewhat more freely. This change made itself evident at once in the greater promptitude with which the regulator acted. Even after only 10 min. such a satisfactory steady state was reached that an increase in the load on the boiler could be followed at once by a reduction of load.

(7) *Increasing the load from* 4·3 *to* 7·7 *tons per hour by suddenly forcing up the by-pass valve and lighting two oil burners, at the same time temporarily adjusting the feed water delivery to* 7·2 *tons per hour. After an interval of* 9 *min. reducing the load from* 7·7 *to temporarily* 4·8 *tons per hour and extinguishing two oil burners, leaving the regulation to take care of the closing of the by-pass valve.*—From Fig. 24 it will be seen that the temperature before the injection point when increasing the load has fluctuated +20 deg. and −18 deg., and when reducing the load −23 deg. and +8 deg. Cent. At the superheater outlet the temperatures varied, when reducing the load, by only +10 deg. Cent., and when increasing the load by −14 deg. Cent., these being the best results obtained in the whole series of regulating tests. The pressure before the by-pass valve has also fallen practically instantaneously from 98 to 90 atm., to rise again within 1½ min. to 98 atm. At the moment when the load was increased the cross sectional area of the by-pass valve was large enough to allow 7·7 tons per hour to pass through at a pressure of 98 atm. In consequence of the fall in pressure to 90 atm., the quantity of steam flowing through approximated only $7{\cdot}7\times 91/99=7{\cdot}08$ tons per hour, *i.e.*, taking 7·7 tons per hour as 100 per cent., the quantity of 56 per cent. flowing through rose immediately to 92 per cent. Since, in condensing turbines, in the neighbourhood of the point where $p=100$ atm. and $t=400$ deg. Cent., as long as the temperature remains constant, the adiabatic fall in pressure within wide limits alters only insignificantly, the results of this test mean that the present boiler, when working under the influence of a centrifugal governor, is capable of supplying instantaneously a quantity of steam corresponding to a sudden increase in the load on the turbine from 56 per cent. to 92 per cent., *i.e.*, by 36 per cent. of the maximum load. It will, however, be recognised that still far greater sudden increases in loading would be permissible without any risk of "boiling over," if it were possible at the start to increase the intensity of the firing and the quantity of feed water delivered. Since demands of this kind were not to be expected in the present plant, the feed water pump and oil burners which have been installed did not allow of such tests being made.

(8) *Still more severe testing of the boiler with respect to "boiling over."**—With a "base load" of 4·8 tons of steam per hour raised by the coal firing, and without changing the feed water delivery or the intensity of firing, the by-pass valve was suddenly opened wide and the boiler left to itself without pressure regulation. According to the curves in Fig. 25, the pressure at the superheater outlet falls in the course of about 3 min. from 98 atm. to 62 atm. and the other pressures and the temperatures accommodate themselves to the new steady condition with only insignificant fluctuations.

The test consequently proves the very important fact that even the sudden drop in pressure from 98 to 62 atm. does not lead to any "boiling over," and that the regulation is quite capable of coping with such sudden changes.

D.—Starting and Stopping the boiler.

Before starting the firing water is circulated through the boiler by means of the feed pump, after opening the above described by-pass valve. The surplus water delivered, along with the steam formed, is at the start led back to the feed water tank, where the steam is condensed. The boiler can then be left to regulate itself, as is shown by the pressure regulating diagram in Fig. 10.

Stopping the boiler.—When the steam temperature has fallen below the permissible height after the fire has been damped down the prime mover is stopped. In consequence of this the pressure in the boiler rises, and as soon as the rise has exceeded 2 atm. the by-pass valve opens automatically, as shown in Fig. 10. The small quantity of steam flowing away is condensed in the feed water tank, the capacity of which is, of course, chosen in such a way that the water in it cannot boil. The feed pump and the regulation remain in operation even some time after the fire has died out and the clinker has been pushed into the clinker hopper. Because of this the tube is cooled down in a short time and the heat accumulated in the setting passes away, so that the whole boiler can be left to itself.

The operations taking place while the boiler is being stopped are shown in Fig. 26. According to the amount of fuel still remaining on the grate—which fuel is turned until it has burned out—the superheat temperature will be maintained for a short time. After the by-pass valve has been fully opened the pressure falls to about 25 atm. in about 1½ min.

Obituary.

HAROLD MEDWAY MARTIN.

The death of Mr. H. M. Martin, which occurred at his home at Croydon on Friday last, takes from the profession a man of outstanding ability, and one whose loss will be felt far beyond the circle of his immediate friends. Modest and self-effacing to the last degree, he was hardly known by sight, except to engineers specially interested in the physical and thermo-dynamical sciences, of which he was an acknowledged master and an able exponent. From time to time his frail figure was to be seen at the meetings of the Institutions, though rarely or never of recent years unless he had been specially invited to speak on some subject which he had made his own. Then, fighting down his natural shyness, and alternating between a nervous hesitancy of speech and an almost explosive rapidity of utterance which was the despair of reporters, he would make his points with the directness born of knowledge and sincerity. His knowledge, both of engineering and other matters, was extensive, but his special interest lay in mathematical physics. Gifted by nature with exceptional mathematical ability, mathematics to him was a tool always sharp and available, and the more valuable in that he was its master and not its servant.

Mr. Martin was born in 1864, and received his early education at the Northern Congregational School, Wakefield. At the age of sixteen, he passed the London Matriculation Examination, and then entered the works of Messrs. Black, Hawthorn and Co., of Gateshead, locomotive and marine engineers, as an ordinary working apprentice. As the result of private study and evening classes he obtained, in 1885, a Whitworth Scholarship, which enabled him to proceed to the Central Technical College, South Kensington. To this scholarship he always attributed his own chance of getting a higher technical education, and he keenly felt the alleged injustice of the modern regulations which now make the scholarship impossible of attainment by the self-taught apprentice. Mr. Martin was also awarded the Clothworkers' Scholarship at the Central Technical College in 1885. Here he studied civil and mechanical engineering under Dr. W. C. Unwin, and mathematics under Professor Henrici, leaving in 1887 with the Diploma of the City and Guilds of London Institute. In the same year he joined the editorial staff of our contemporary *Engineering*, and remained with that journal until his death—a period of more than forty-six years. During this time he did original work on a great variety of subjects, the results being almost invariably published anonymously. He developed the theory of the short cylindrical boiler, in which the shell stresses are modified by the constraining influence of the ends. Other investigations included the strength of hooks, the strength of rotating discs, the steam leakage through labyrinth packings, the lubrication of gear teeth, and the theory of convergent nozzles at speeds beyond the critical velocity. An important piece of work was a formulation of the laws of heat transfer in condenser tubes, previously discordant results being shown to be explicable on a rational theory. Bridges and masonry dams also interested him, and he investigated the theory of the stiffened suspension bridge.

Steam turbines early attracted his attention, and he developed a theory for the design of compound reaction machines. His views were, indeed, held in high respect by turbine designers, both in this country and abroad, and his advice was frequently sought and as readily given. As an exponent or critic of other men's work, he also rendered invaluable services. No one has probably done more than he did to familiarise engineers with the physical and thermo-dynamic laws underlying the properties of steam, and to explain the rational formulæ of Callendar. His simple exposition of the "Elements of the Lanchester-Prandtl Theory of Aeroplane Lift and Drag" will not be forgotten by engineers interested in aeronautics, nor will an earlier generation fail to remember a really delightful little book on "Statically Indeterminate Structures and the Principle of Least Work," now out of print, in which the applications of Castiglione's principle were clearly explained. Mr. Martin's only other book was "The Design and Construction of Steam Turbines," now also out of print.

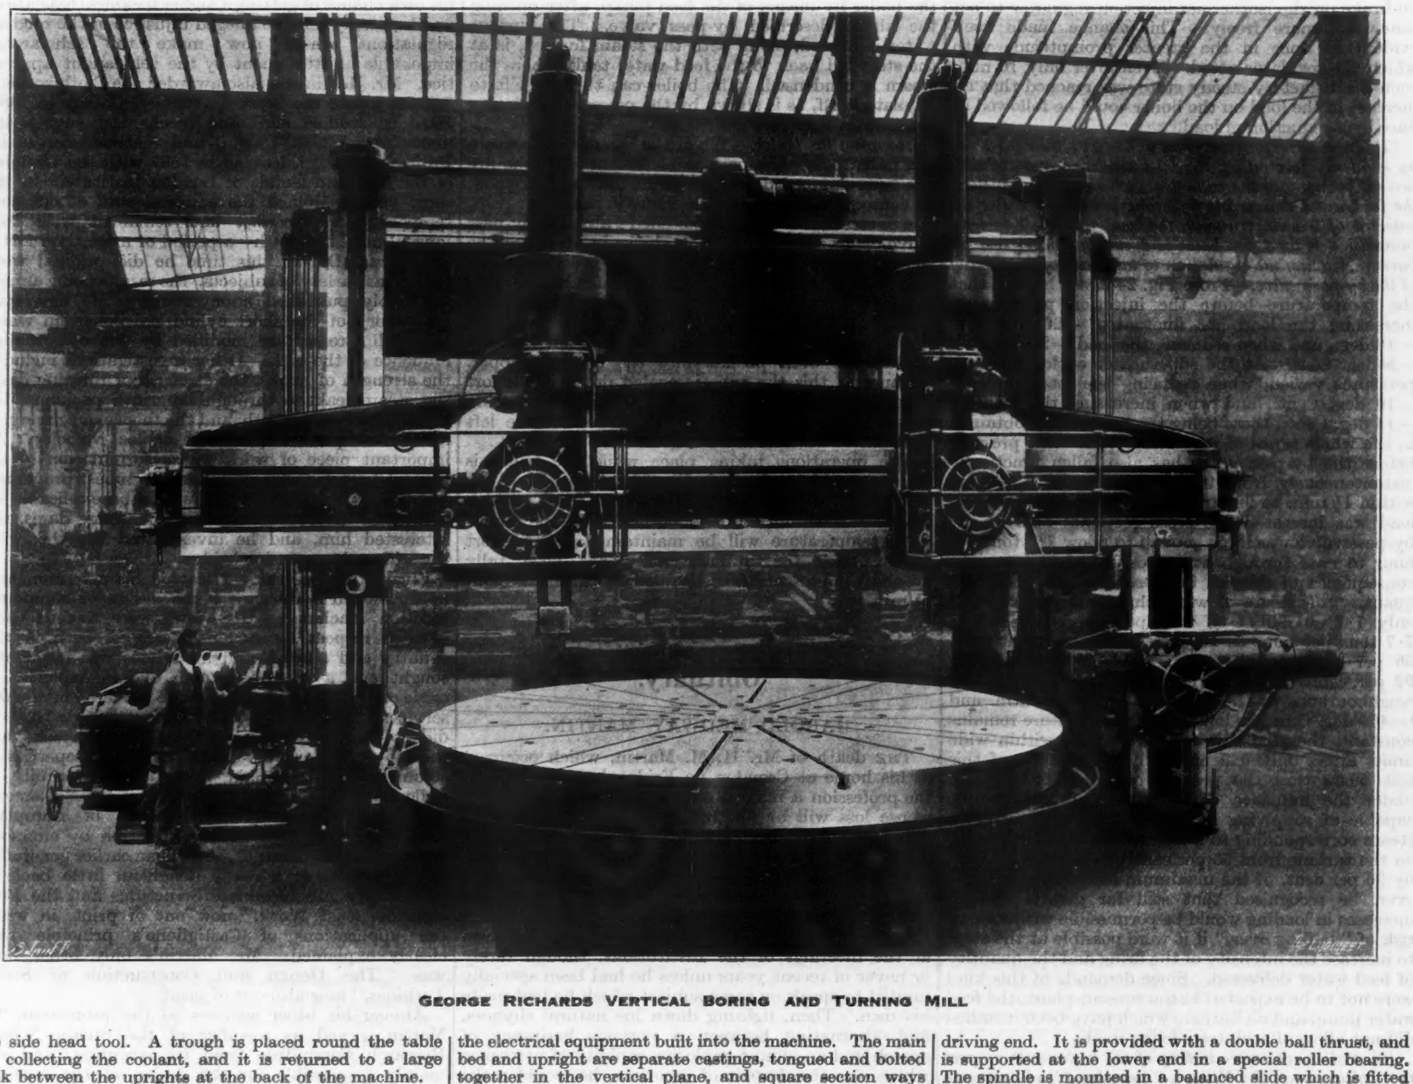
Among his other services to the profession, Mr. Martin served as member of the Steam Nozzles Research Committee from its inception, and was mainly responsible for the design of the sensitive and accurate testing apparatus with which the experiments were made. He was also an original member of the Sub-committee on Lubricants and Lubrication, appointed by the Government in 1917, and was responsible for initiating the experiments at the National Physical Laboratory on the effect of pressure on viscosity. He took a great interest in the Junior Institution of Engineers, joining as a member in 1907, and being given honorary membership in 1921. He was elected member of the Institution of Mechanical Engineers in 1930, and the distinction of Fellowship was conferred upon him by the Council of the City and Guilds of London Institute in 1931, on the grounds of his contributions to the advance of industry and the value of his original researches.

---

* "Priming" hardly conveys the meaning of the action.—Ed. The E.

Vertical Boring and Turning Mill.

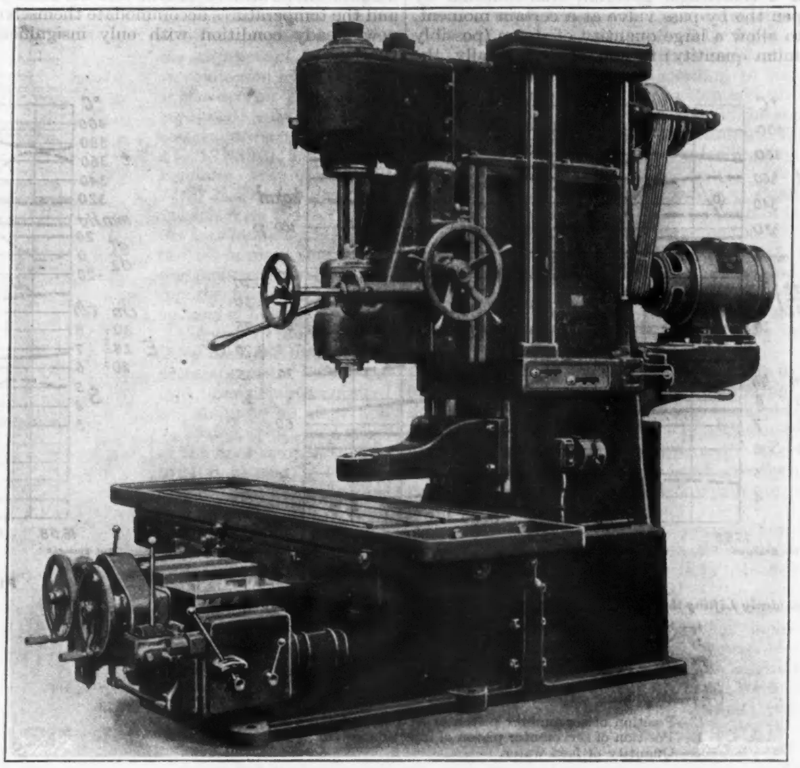
The engraving at the foot of this page shows a large vertical boring mill just completed by George Richards and Co., Ltd., of Broadheath, near Manchester. It is fitted with two standard heads on the cross slide, and also a side head, the latter having a separate feed box and being quite independent of the standard vertical heads. The table is 16ft. diameter and work up to 18ft. diameter can be accommodated. The machine admits 8ft. under the toolholders, and 9ft. under the cross slide, while the tool bars have a down feed of 5ft. The side head has 30in. vertical traverse and 27in. horizontal traverse. Twelve feeds, ranging from 1in. to 0·03in., are provided to the two vertical heads, both horizontally and vertically. The side head has four vertical feeds, ranging from 0·24in. to 0·07in., and four horizontal feeds ranging from 0·12in. to 0·036in. Both fine and rapid hand feed motion is also provided to the two vertical heads and the side head. In the case of the vertical heads these feeds can be applied from the operating platforms. Rapid power traverse is obtainable at all the heads, both vertically and horizontally, and this motion and also the raising and lowering motion to the cross slide is driven by a separate 15 H.P. electric motor mounted on top of the cross girth. The gear-box gives twelve mechanical changes of speed to the table, ranging from 10 to 0·8 r.p.m. The main driving motor, mounted on top of the gear-box, is 45 H.P., of the constant-speed type. Lubrication has received special attention. The gear-box has flood lubrication, and other main bearings in the base are supplied with oil by gravity feed, while the main table bearing has an oil reservoir fed by a drip feed lubricator. A rather unusual feature on so large a machine is the provision of a coolant system to the cutting tools. For this purpose there are two pumps driven from the main gear-box, one supplying coolant to the two vertical tools and the other supplying the side head tool. A trough is placed round the table for collecting the coolant, and it is returned to a large tank between the uprights at the back of the machine.



George Richards Vertical Boring and Turning Mill

High-Speed Milling Machine.

Fitness to purpose and cleanness of design are the outstanding characteristics of the motor-driven high-speed milling machine illustrated herewith. The machine is one of the latest types built in three sizes by Craven Brothers (Manchester), Ltd., Reddish, Stockport, for use with high-speed cutters. It is of the all-geared type, with the electrical equipment built into the machine. The main bed and upright are separate castings, tongued and bolted together in the vertical plane, and square section ways are provided for both the spindle slide and table. Unit construction has been adopted for the various sections.



Craven High-Speed Milling Machine

The gear-box on top of the upright provides sixteen changes of speed through heat-treated steel gear wheels mounted on splined shafts, the latter running in ball and roller bearings and starting and stopping being controlled by a friction clutch and brake.

The machine is driven by a constant-speed motor and a texrope drive to the clutch on the gear-box shaft, and the control mechanism is built into the upright. The spindle of high-carbon heat-treated steel is splined at the driving end. It is provided with a double ball thrust, and is supported at the lower end in a special roller bearing. The spindle is mounted in a balanced slide which is fitted to the square section ways on the upright, the slide having both fine and quick adjustment by hand, with quick locking arrangements and a vernier for setting the depth of the cut. The cutter mandrel support is designed for use on heavy profile and slab-milling operations. It is adjustable vertically, and when not required can be pivoted clear of the table.

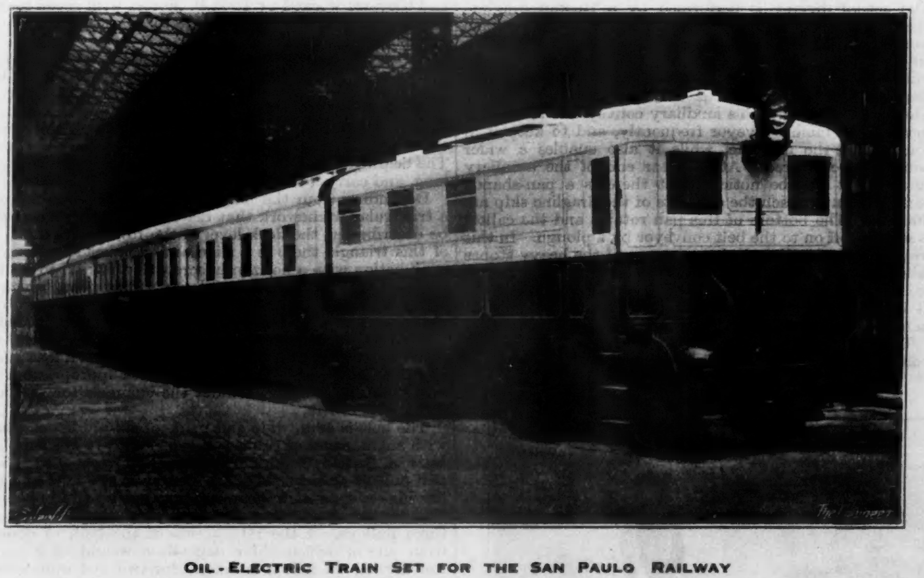
The transverse slide for the table has very wide ways and a taper strip adjustment. Screws of large diameter are provided for feed and quick traverse in both directions. Each screw has a ball thrust and the table can be easily adjusted in both directions by means of a hand wheel. The feed control and quick power traverse controls are by means of one lever of the "joy-stick" type. The feed is engaged by a drop worm having trip action which operates in any direction, and the quick traverse is engaged through friction clutches.

The feed gear-box provides sixteen rates of feed, from 1½in. to 24in. per minute, and there is a safety slipping clutch. Feed and quick traverse drives are obtained by a separate motor built into the feed gear-box, and a mechanical connection automatically disengages the feed, should the operator stop the spindle with the feed engaged. "One shot" pumps are used for supplying oil to the moving parts wherever possible, and in other places an oil gun is used. This machine is capable of removing 30 cubic inches of cast iron per minute when using a 12in. cutter of the high-speed type. Its principal dimensions are as follows:—

Diameter of spindle over splined driving end	4in.
Working surface of table	6ft. by 2ft.
Longitudinal traverse of table	5ft.
Transverse traverse of table	3ft.
Distance from centre of spindle to vertical slide of main frame	2ft. 3in.
Maximum distance, table to spindle nose	3ft.
Minimum distance, table to spindle nose	7in.
Number of spindle speeds	Sixteen
Range of spindle speeds	15–250
Number of feeds	Sixteen
Range of feeds	1½in. to 24in.
H.P. of driving motor	20
Speed of driving motor (approx.), r.p.m.	1200
Floor space occupied (approx.)	11ft. by 12ft. 9in.
Approx. net weight, exclusive of electrical equipment	10 tons

Oil-Electric Train Set for Brazil.

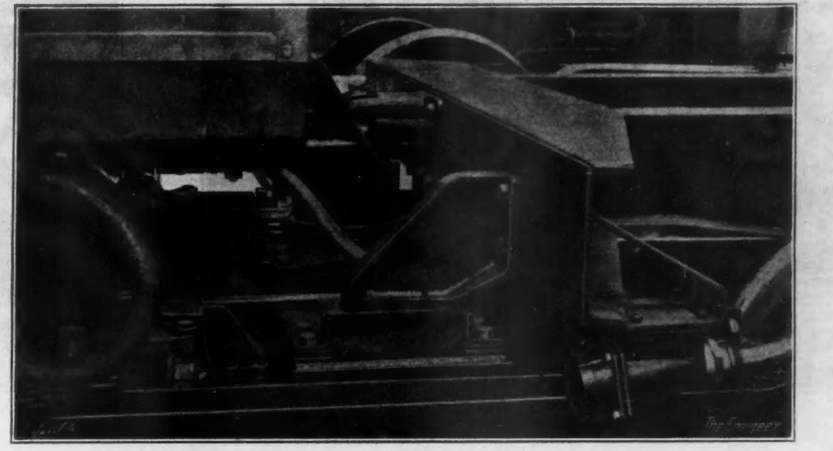
A VERY interesting oil-electric train set has recently been completed at the Scotswood Works of Sir W. G. Armstrong, Whitworth and Co. (Engineers), Ltd., for rapid and frequent services on the San Paulo Railway in Brazil between the port of Santos and San Paulo, a distance of roughly 49 miles. Owing to the exigencies of the service involving, as it does, the traversing of an incline of 1 in 12½ to an altitude of 2600ft. by means of a ropeway, it is necessary that the train set shall conform to very particular requirements, inasmuch as not only will it have to work at different altitudes at very short intervals, but owing to the length of passing loops on the line the overall length has to be restricted.



OIL-ELECTRIC TRAIN SET FOR THE SAN PAULO RAILWAY

The train set is of three-coach formation with a power unit articulated to the first coach. The second and third coaches also are articulated, whilst connection between the first and second coaches is by simple draw gear. The train set has been designed for a maximum speed of 65 m.p.h., the drive being by means of four motors, two being mounted on the bogie under the power unit and two on the rearmost bogie, thus spreading the tractive force over the whole length of the train. Current is supplied by the main engine generator set, the engine being a six-cylinder Armstrong-Sulzer airless injection, completely enclosed, traction type, running at 750 r.p.m., with automatic forced feed lubrication to all parts. Safety devices are provided in the oil and water circuits, which shut down the engine in case of failure of supply of either the oil or water. There is also a special engine control device fitted, whereby at a moment's notice the output of the engine may be varied so as to adjust it to suit working at sea level or at an altitude of 2600ft. The starting of the engine is effected electrically. An auxiliary engine generator set, which runs during the operating time of the train, takes all auxiliary loads, thus obviating the use of heavy batteries. Cooling of the water and oil for the main engine is by means of a panel type cooler and electric fan placed on one side of the power unit. Immediately above the auxiliary engine is placed the cooling water tank, and alongside this tank in the roof of the power unit is the fuel service tank. The main fuel tank is placed at the side of the power unit. A rotary exhauster driven by an electric motor for the vacuum brake is placed towards the rear of the power unit.

The main engine is mounted on two longitudinal I beam members with channel cross stiffeners. The power unit bogie is arranged with plate sides and Isothermos axle-boxes and springing is provided by leaf springs. Special attention has been paid to the necessity for light weight, and consequently all the sections have been adopted with a view to securing rigidity with a minimum of weight.



THE GRESLEY ARTICULATED BOGIE ATTACHMENT

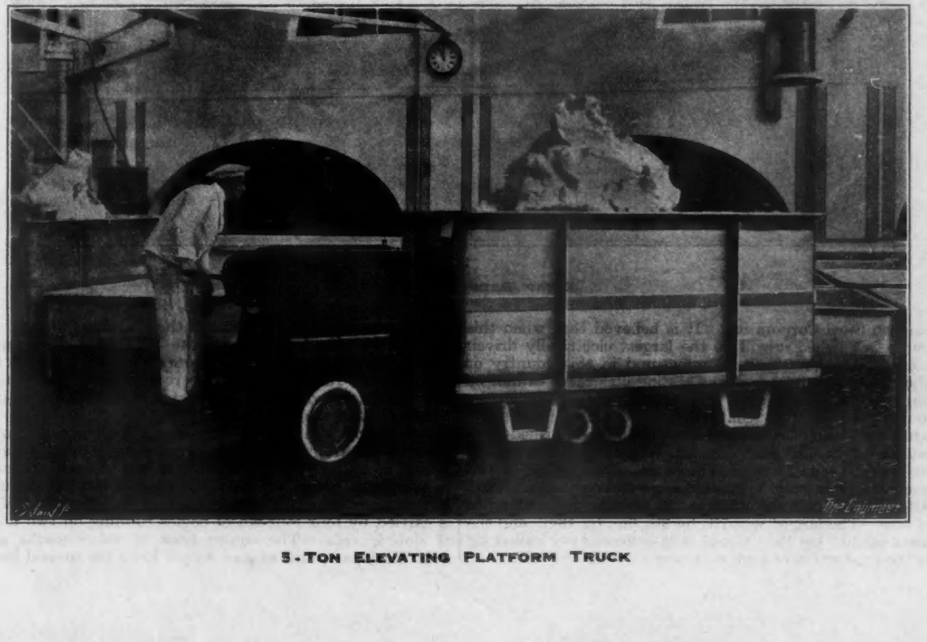
Braking is effected by means of standard clasp brakes on both sides of all four wheels. The axle-suspended motors are carried on shock-absorbing buffers at the nose. The articulated bogies are of special light-weight construction, and the load from the Gresley articulating joint is transferred to the bogie frames through double helical springs by means of a bolster; springing to the axle-boxes is of orthodox form with leaf springs. The bogies under the coaches are also of very light weight and the wheels are braked on both sides.

The main framing of the coaches consists of braced longitudinal girders of all-welded construction. The cross members supporting the coachwork are of light channel section and are bolted to the main longitudinals. The coach bodies are of very light all-metal construction, mounted on the underframes, and are not built integral with the underframes. The body framing consists of pressed steel pillars of U section. The flanges are riveted to the waist rails and cant rails, the flanges being cut away between the inside waist and the cant rails to allow of the windows and louvres being easily removed. The exterior panels are of light sheet steel, riveted to each pillar, and are covered with Carbolostic paint to prevent drumming. All the compartment windows are of the full drop type and are fitted with an inside "Alpax" louvre. Both windows in the driver's compartment are glazed with safety glass and an electric windscreen wiper is fitted to the fixed window in front of the driver. The interior panelling is of plywood covered with leather to the waist line in the first-class compartments and teak finish above, whilst the second-class compartment is painted cream and brown. The total seating capacity is for 100 first-class and 68 second-class, the seats in both classes being of the reversible type. In addition to the three lavatories, a buffet has been arranged, fitted with racks and cupboards and with a small ice chest.

A driving compartment is arranged at each end of the train so as to permit of a shuttle service being run and to obviate the turning of the train set or terminal movements of any description. Control of the train is entirely automatic and is of the Armstrong patented system of voltage control, whereby the full horse-power output of the engine is economically utilised throughout the whole speed range of the train. The complete train weighs 92·6 tons in running order and 103·6 tons loaded with passengers and luggage.

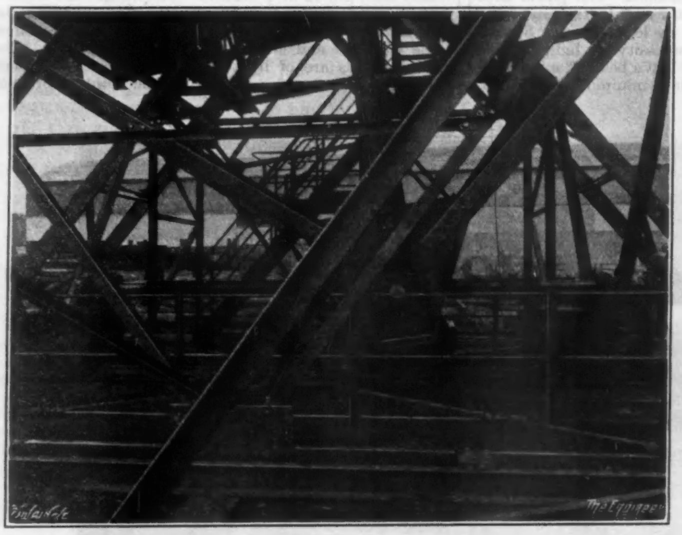
5-Ton Elevating Platform Truck.

THE six-wheel elevating platform truck illustrated has a 5-ton load capacity, and is made by Wingrove and Rogers, Ltd., of Arundel Chambers, Strand, London. The principle of working is well known, but, briefly, goods are loaded on a stillage platform raised 13in. from the floor, and the truck is driven between the stillage legs. The operation of a switch raises the truck platform and stillage 4½in. off the ground in 9 sec., and truck and load are driven away. The elevating motor is tripped automatically at the high and low limits and an electric brake is automatically applied to prevent overruning. The motor can be stopped and reversed at any point desired. The platform is connected to the lifting mechanism by a collapsible link, so arranged that if the truck is accidentally driven into an obstruction, the lifting mechanism is protected. The travelling controller has three speeds in each direction and is interlocked with the brake pedal, so that application of the brake cuts off power. For entering stillage, provision is made for inching on first speed by the use of the brake pedal only. Steering is by tiller moving in a vertical plane operating on all six wheels, giving a

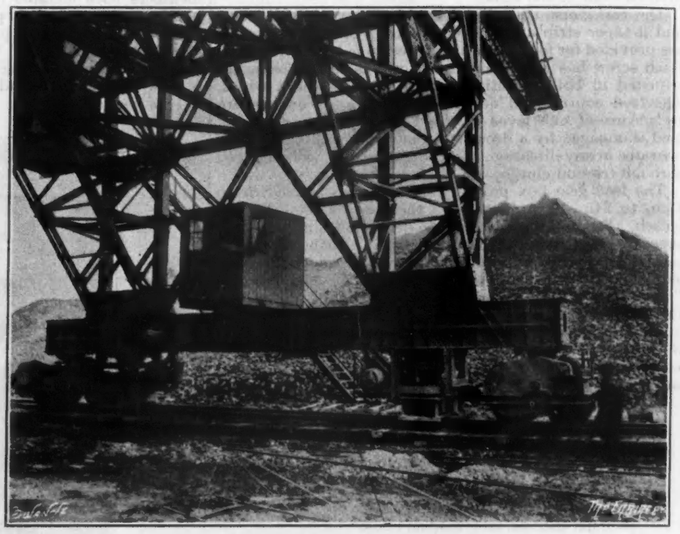


5-TON ELEVATING PLATFORM TRUCK

CANTILEVER CONVEYOR FOR A BRICKFIELD



Gear for Tilting the Conveyor

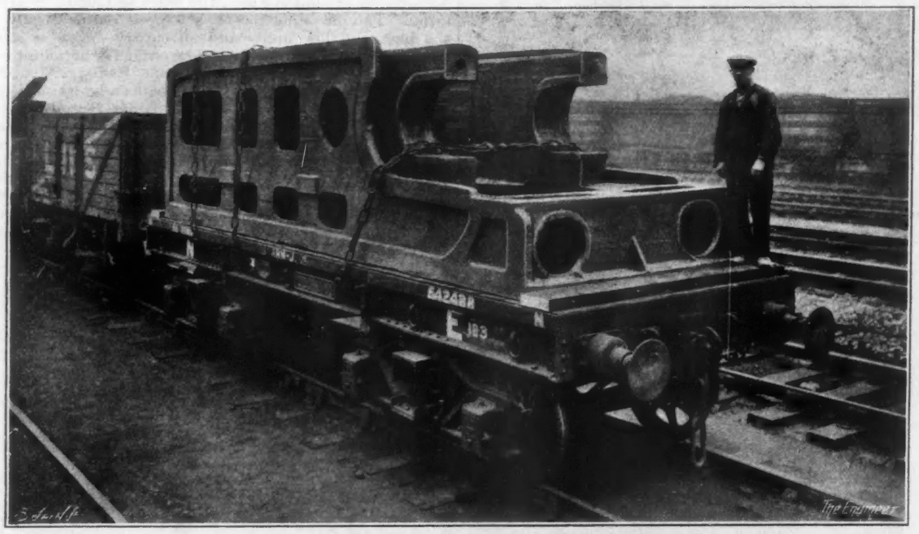


Supporting Bogies and Jacks

turning radius of 6ft. 6in. to the centre of the truck, or, in other words, the truck will turn completely inside a circle of 18ft. diameter. Special attention has been paid to the steering design. Not only is the turning circle claimed to be better than that of trucks of smaller capacity, but owing to the use of stub pin bearings of special design and an adaptation of the maker's "G" type steering principle, the effort required of the driver is even less than that on a 2-ton capacity truck. The four-wheel trailing axle is articulated for traversing uneven ground, and 5in. ground clearance is allowed for passing over the peak of inclined ramps. The driving and elevating motors are of specially light construction having aluminium frames. This lightness is not obtained at the expense of active material or by reducing the air gap, but by the use of laminated split poles of special construction. The motors are capable of withstanding occasional overloads of 300 per cent., and normally work at the one-hour rating. The unladen weight of the truck complete with Edison battery in running order is only 43 cwt.

An Intricate Casting.

In the accompanying illustration is shown one of three castings of similar size recently made by the English Steel Corporation at the Cammell Grimesthorpe steel foundry. These three castings, together, make up the main pump bedplate for the electrically driven hydraulic high-pressure three-throw ram pump, which is being supplied by Vickers-Armstrongs, Ltd., of Elswick, for the 7000-ton press now being installed at the Vickers works of the English Steel Corporation. It is believed that when this pump is finished it will be the largest electrically driven pump of its kind ever manufactured in this country or abroad. The intricacy of the casting illustrated cannot be appreciated at a glance. The difficulties with which the foundrymen had to contend will be better understood when some dimensions are mentioned. The finished casting was 22ft. 6in. long, 7ft. 4in. wide, and 6ft. deep. It weighed 30 tons 12 cwt. Yet its cross ribs and slide bed members were only 1½in., and its walls only 1¾in. thick. Altogether it was necessary to use seventy different types of core. The largest was 7ft. by 3ft. 6in. by 18in., and the smallest 2in. by 1in. Great skill is necessarily called for in the production of such a casting.



Pump Bedplate Casting

A Cantilever Conveyor for a Brickfield.

Recently we had an opportunity of inspecting a conveyor of unusual form which has been designed by the engineers of the London Brick Company and Forders, Ltd., for use at the Stewartby Works of the company, and manufactured for them by Robert Boby, Ltd., of Bury St. Edmund's. It is illustrated herewith and on page 522. The purpose of this conveyor is to remove the overburden of callow from the brick earth deposit and dump it back in the worked-out pit. The actual digging is performed by a Ruston dragline excavator mounted on caterpillar tracks. This machine works on the natural ground level and dumps the callow on to a short conveyor mounted on a bogie, running on rails on the top of the brick earth. This conveyor feeds the main conveyor which is the subject of this article. The object of having this auxiliary conveyor is to obviate moving the main conveyor frequently, and to keep it in touch with the dragline, while it also enables a wider bench to be cleared. At the rear end of the auxiliary conveyor it will be noticed that there is a pan-shaped receptacle into which the contents of the dragline skip are dumped. The bottom of this pan rotates and the callow is scraped off on to the belt conveyor by a plough. In this way the belt is relieved of the impact of the heavy stones falling out of the skip and an even feed is provided. This conveyor is 295ft. long between the centres of the pulleys. It is 48in. wide, and is driven at a speed of 100ft. per minute by a 25 H.P. electric motor.

The business of the main conveyor is, as we have already pointed out, to carry the callow away from the working face and to dump it in the back of the pit. For this purpose it must be able to command the bench, which is some 60ft. above the level of the bottom of the pit on which its substructure runs and also give room for the passage of the 10 cubic yard Ruston excavator that does the actual digging out of the brick earth.

The callow conveyor, which, it will be seen, is cantilevered out from either side of a central tower, has a length of 295ft. over the centres of the end pulleys, and is 48in. wide across the belt. The tower is a substantial lattice work structure surmounted by a pyramid, which is carried by four four-wheel bogies running on two lines of double rails. The centre lines of these tracks are 46ft. 6in. apart, and so give ample room for several lines of service trucks through the portal. The bogies are equipped with motors and gear for travelling the tower at a speed of 43ft. per minute. Between the two bogies, on either side, there are jacking gears, which are used to relieve the wheels from weight when the conveyor is at work. These jacks take the form of a box girder which spans the running rails and is guided in a frame depending from the main girders of the tower. Each of the box girders can be pushed down by a large square-threaded screw and nut driven by its own electric motor. The motors are all controlled from a cabin on the main girder and can be made to keep the tower vertical, regardless of any inequalities in the elevation of the track. The total load which these jacks have to accommodate is some 300 tons, and they are worked by 15 H.P. motors with speed reduction gearing having a ratio of 178 to 1 between the armature shaft and the lifting screw.

At the top of the pyramid on the tower there are two journal bearings which carry the whole weight of the cantilevered conveyor, for it is possible to tilt the conveyor through an angle of 12 deg. above and below horizontal, which gives a latitude of about 40ft. at the end of the conveyor for adaptation to the contour of the bench. The bearings are simple journals, 8in. in diameter by 12in. long, and carry a total load of 103 tons.

Depending from the bottom of the cantilever there is a triangular framework that reaches down to what might be described as the deck level of the tower. At the apex of this triangle there is a slide and crosshead working in conjunction with a horizontal screw that is used to set the angular position of the cantilever. This gear, which is well represented in our engravings, is driven by its own electric motor of 25 H.P. through worm reduction gearing.

The cantilever itself needs little description, as it is a simple structure, 307ft. 6in. long overall, with a maximum width of about 20ft. It is provided with appropriate wind bracing and naturally includes the channels for the conveyor belt rollers.

The belt is 48in. wide and made of six-ply 32-oz. duck, with a $\frac{1}{16}$in. cover of rubber on each side. It was supplied by the British Goodrich Rubber Company, Ltd. The two pulleys at the ends of the cantilever are fixed and the driving and tension gear are arranged at the centre. The tension gear takes the form of a simple fold over three pulleys, on the return side of the belt, of course, from one of which there depends a weight of 8½ cwt. For driving the belt it is taken over two cast iron drums, 39in. in diameter by 50in. face, which are driven through a 20 to 1 David Brown worm reduction gear by a 25 H.P. motor. This gives the belt a speed of 100ft. per minute, and enables it to convey 450 tons of callow per hour. On the carrying side the belt is supported by five-pulley type troughing rolls that run on tapered roller bearings. The bearings are carried on tubular steel spindles, and are arranged for forced lubrication. On the return side the rollers are plain solid-drawn tubes running on tapered roller bearings.

At the feed end of the main conveyor there is superimposed a short length, some 7ft. or so, of feed conveyor, which is driven by gearing from the end pulley of the main conveyor. This comparatively inexpensive belt takes the impact of the feed and thus saves the long main belt from unnecessary damage. At the discharge end the callow is simply dumped off the end on to the ground below.

The electricity supply for the machine is brought in by a trailing cable connected with the mains at a pressure of 400 volts and a periodicity of 50 to the main control cabin just below the deck level, in which there are arranged the necessary transformers and controllers for the several motors.

Finally, we should like to remark that although a brick earth pit is generally associated with mud and discomfort, this machine seems to have been so devised as to keep its working parts habitually clean.

It is announced that at the Fourteenth Exposition of Chemical Industries, which is to be held from December 4th to December 9th in the Grand Central Palace, New York, a novel form of closing the collapsible metal tubes used for such purposes as vending adhesives is to be demonstrated. No details of the principle are yet available.

Heat Liberation and Transmission in Large Steam Generating Plants.*

By E. W. Robey, M.I. Mech. E., and W. F. Harlow, A.M.I. Mech. E.

Steam generation continues to occupy a position of prime importance in industrial processes, and the problem of converting the maximum amount of the potential energy available in various fuels into the heat energy of steam in the cheapest possible manner still demands the closest examination from all angles. In presenting this paper the authors make no pretence of discussing all aspects of a subject which provides material for innumerable papers. Their object, as a result of their experience as practical combustion engineers, is to present certain considerations which have hitherto been somewhat neglected in practice and which seem to indicate that some revision of prevailing ideas is necessary. By a closer observance of certain fundamental principles considered here improvement in existing practice appears possible.

The operation of steam raising resolves itself into two distinctly separate processes, namely :—

(1) The liberation of the heat available in the fuel.

(2) The transmission of the liberated heat to the steam.

These, although proceeding to some extent simultaneously, should be considered independently.

The former process will be considered first, and as the paper is intended to deal principally with the combustion of coals by means of mechanical stokers, the discussion of the first part of the problem will be confined chiefly to the burning of solid fuels by this method.

The Heat Liberation Process.

Although the combustion of coal is a chemical reaction of the most commonplace occurrence, exact information on the manner in which the process takes place and the conditions necessary for the best results was until recent years very incomplete. The demand for larger and more efficient steam-raising units, arising from the development of electric power, led to a much closer examination of the problem, and the results of a large amount of research work are now recorded. At the same time, additional knowledge of certain aspects of the subject is still required and further research into these matters is desirable.

In order to liberate completely the heat available in any fuel it is merely necessary to burn it so that no combustible matter, solid, liquid, or gaseous, is rejected, either with the gaseous products of combustion or with the solid refuse. This, of course, is a simple matter, given unlimited air and unlimited time.

In a boiler plant, however, the fuel must be burnt at a high rate in order to limit the size and cost of the steam-raising equipment, and the operation must be accomplished with the minimum quantity of air with which complete combustion may be obtained, in order to minimise the loss by rejection of heat to the stack. This must be done without causing the formation of any appreciable quantity of smoke. Under these conditions the operation presents more difficulty.

The recognition of these requirements has naturally stimulated the development of firing equipment capable of their fulfilment.

It may be of advantage here to enunciate some axioms which, although perfectly well known, are frequently neglected in practice and in argument. They are as follows :—

(1) The quantity of heat produced from a unit quantity of fuel is unaffected by any increase in the quantity of air over the necessary amount.

(2) The quantity of combustion air governs the amount of flue gas, which is the medium by which far the greater part of the heat is conveyed.

(3) The amount of heat rejected to the atmosphere is, at constant temperature, proportional to the amount of flue gas.

(4) The power required to impel or induce the gases through the heat-absorbing units increases with their mass.

(5) At constant pressure difference any increase in the amount of excess air decreases the fuel-burning capacity of the plant.

Generally speaking, and below certain limits, the smaller the proportion of excess air the greater the difficulty in releasing the total amount of heat available in the fuel, for not only is solid combustible matter liable to be rejected with the furnace refuse, but gaseous combustibles are likely to escape with the products of combustion.

The advantages gained in the efficiency of the heat transmission process due to the use of a small excess of air may result in smoke and may easily be offset or exceeded by the resulting inefficiency of the heat liberation process, due to loss of unburnt combustible matter.

The Development of the Mechanical Stoker.—The difficulties inherent in the hand-fired system with natural draught resulted in the development of the chain-grate stoker, by which means a fuel bed of uniform thickness could be continuously introduced into the furnace without any appreciable influx of uncontrolled air. This was followed by mechanical draught, and the result of this and other developments is the forced draught mechanical stoker, which is to-day perhaps the most widely used equipment for steam-raising purposes. Notwithstanding its general success, however, there is still room for improvement, not so much in the mechanical design of the stoker, as in its manner of application, particularly in the system by which the combustion air and fuel are brought into association.

In the early installations of mechanical stokers with natural draught the machines were set a few feet from the boiler tubes under a refractory arch, the function of which was to ignite the fuel and form a deflecting channel for the volatile gases to direct them into the air stream rising through the rear of the grate.

Comparatively good results were obtained with these arrangements, but to avoid smoke the amount of excess air necessary was considerable and the rate of combustion was limited by the stack draught available. This also limited the thickness of the fuel bed to 4in. or less, for the less the resistance of the fuel bed the greater the quantity of air induced through it by a given draught, and, with a constant CO_2 content, the greater amount of fuel would be burnt.

Notwithstanding the later adoption of mechanical draught, the same type of settings and fuel bed thickness persisted for years. The continued cost of maintaining arches eroded at the higher gas velocities resulted in the evolution of archless settings in which it was found possible to burn many classes of fuel satisfactorily, provided that there was sufficient furnace volume to allow of the diffusion of the leakage air and weak gases into the rich gases from the front of the grate, and to complete combustion in the furnace. Many installations of mechanical stokers are operating in such archless settings at the present time and no difficulty whatever in igniting or burning the fuel to ash is being experienced. This has brought into vogue what has been referred to as the "furnace type" of boiler, in which the height of combustion space above the fuel bed is several times greater than in the case of the original natural draught stokers referred to previously.

In order to prevent smoke when using a minimum of air it has, however, been found necessary with this type of furnace to inject into it, above the grate, a proportion of the combustion air. This secondary air, preferably introduced into the distillation zone at the front of the stoker, thus not only provides oxygen for the early combustion of the volatile gases, but by creating turbulence renders available for combustion the inevitable amount of adventitious air from the rear of the grate.

The subject of secondary air is an important one and merits considerable discussion, as its full significance does not appear to be generally appreciated.

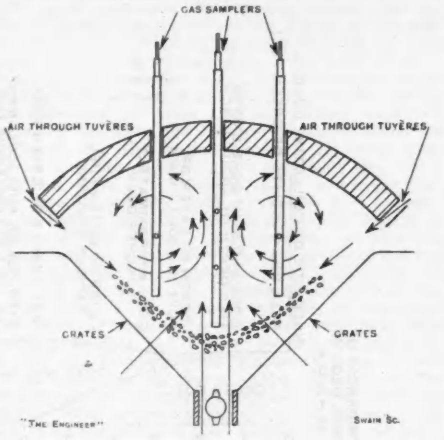


FIG. 1—*Method of Admitting and Sampling Secondary Air.*

The Application of Secondary Air.—Secondary air, mostly induced by natural draught, has been provided for in designs of furnaces at least as far back as 1830, but nevertheless it was, until a few years ago, the exception to find any large externally fired boiler equipped in this manner, and in those cases it was generally inadequate in amount or incorrectly applied. Even to-day much divergence of opinion exists as to its correct application.

In the author's opinion, the advantages of secondary air in large steam generator practice have never been fully explored, because of the mistaken idea that in order to burn coal with a minimum of air it is necessary to pass the bulk of it through the fuel bed, and that secondary air approximating to 10 per cent. in volume is only advantageous for the prevention of smoke from bituminous coals.

In order to appreciate fully the function of the secondary air, it may be helpful to study the manner in which the combustion process takes place, both in the fuel bed and in the space above the fuel bed. The theory appertaining to the use of secondary air is, in a general manner, perfectly well known, but the authors think that the full importance of the subject may be better understood by consideration of the experiments carried out in 1917 by H. Kreisinger, F. K. Ovitz, and C. E. Augustine, as recorded in Technical Paper No. 137 and its companion report, Bulletin No. 135 of the U.S. Bureau of Mines, since these appear to be the most thorough investigations into the process of combustion in and above the fuel bed, that have been recorded.

The first-mentioned deals with the combustion in the fuel bed of hand-fired furnaces, and proves that when bituminous coal or anthracite or coke is being burnt, practically all the oxygen in the air entering the fuel bed from below has disappeared at a level of approximately 4in. above the grate.

The rate of burning varied between 20 lb. and 185 lb. per square foot per hour with fuel beds 6in. or 12in. thick, maintained constant during the experiment. The investigators state that the ratio between the weight of air supplied and the weight of fuel gasified remained constant at about 7/1, so that only about half of the 15 lb. of air required to burn the fuel can be supplied through the fuel bed, and the balance must be supplied above to burn the combustible gas which is present on the surface of the fuel bed to the extent of 20 to 32 per cent. of the total.

Later, in 1922, Audibert carried out experiments to ascertain the effect of leakage air and to find how the gas composition varied when starting with a compact level bed of coke and allowing it to burn away under a constant rate of air supply, until the temperature of the gases began to fall. His grate was 3·3ft. by 1·65ft. built at one end of a horizontal combustion chamber and connected to a flue 30ft. long. The gas samples were taken in such a way as to be representative of the average composition.

He found that the composition of the gases varied with the rate of air supply and this seems to conflict with the conclusions of the U.S. Bureau of Mines. This is probably explained by the fact that his type of experimental furnace allowed of a greater percentage of leakage at high rates of air supply than at lower rates. The interesting fact, however, is that he found that the gases from a 6in. fuel bed contain a large proportion of combustible gas and little oxygen, thus confirming the finding of the U.S. Bureau of Mines.

In a modern chain grate stoker the leakage air forms a far smaller proportion of the total air than in Audibert's furnace, because the grate area is many times larger and the length of the boundaries of the fuel bed does not increase proportionately. Moreover, the design of the modern stoker is such that leakage air is reduced to a minimum. It follows therefore that without secondary air equipment, the only passage for the admission of the air necessary for the complete combustion is through the grate surface. To permit of this, the fuel bed has to be burnt off prematurely and restricted in depth. The disadvantages of this method of operation will be shown later.

The second paper referred to above, namely, Bulletin No. 135 of the U.S. Bureau of Mines, deals with the combustion process in the space above the fire and will now be considered.

The material presented in this report consists principally of the results of about a hundred tests to determine how the gas composition varied in a long combustion chamber fired by a "Murphy" side-feed mechanical stoker, when coals of varying characteristics were burnt. In all these tests, secondary air was admitted at quite a low pressure of 0·1in. to 0·2in. of water through a series of tuyeres extending over the whole length of the fuel admission openings. A section through the grates indicating how the secondary air was admitted, is shown in Fig. 1.

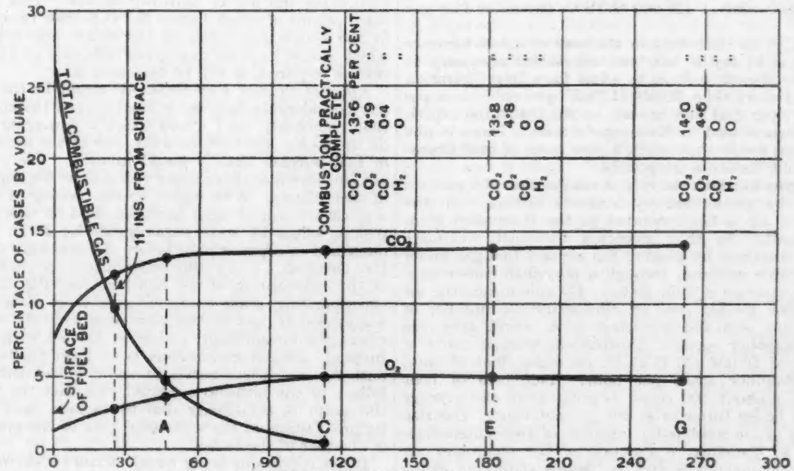

FIG. 2—*Curves Showing Progress of Combustion in Experimental Flue Fitted with Murphy Mechanical Stoker with Secondary Air (U.S. Bureau of Mines).*

Fuel, Pittsburgh screenings ; combustion rate, 35·6 lb. per square foot per hour. All points plotted are the average of not less than six samples taken simultaneously at each section.

The variation of the principal constituents is shown graphically in Fig. 2, which clearly illustrates the combustion process in the space above and beyond the fuel bed. It will be observed that the combustion proceeded at first very rapidly and then at a decreasing rate, until at the section C only 0·4 per cent. of combustible gas remained. Beyond this section the CO_2 content continued to rise and the O_2 content to fall at a slow but definite rate up to the last section at which samples were taken, showing that oxidation and therefore liberation of heat was still taking place. Due to the reduction in the amount of combustible matter it is obvious that no flame would be evident after the gases had passed section C ; in fact, visible evidence of combustion would probably disappear before this point was reached. The fact that slight oxidation was subsequently proceeding, however, indicates definitely that a certain amount of heat was being liberated in the zone beyond the flame. Although this matter was not referred to by the investigators, who consider that to all intents and purposes the process was completed at C, the continued release of heat in this stage of the operation is important when considering the performance of heat-absorbing equipment, as shown hereafter.

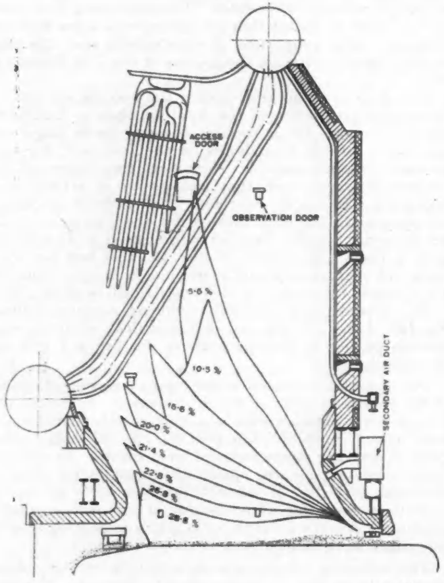
---

* The Institution of Mechanical Engineers.—Abridged.

In addition to combustible gases, a large proportion of tar and a certain amount of soot was present. At 11in. from the fuel bed the tar and soot had almost disappeared, and beyond this point were completely absent. The methane (CH_4), which is also present at the surface of the fuel bed, quickly disappeared in a similar manner.

The soot, tar, and methane resulted from the distillation of the volatile matter in the coal, and, discussing the combustion of this volatile matter, the investigators reported that "All hydrocarbons are unstable at furnace temperature, and unless enough air to ensure complete combustion is quickly mixed with them at the time they are distilled, they are quickly decomposed, the ultimate product consisting mostly of soot, H_2, and CO. At a distance of 1ft. or 2ft. from the surface of the fuel bed only a very small amount of hydrocarbons can be found in any state, gaseous, liquid, or solid. The persistence of CO in the furnace gases is not due to the difficulty of burning it, but to its constant formation by the reaction between soot and H_2 and CO_2. The cooling surfaces do not cause the formation of soot, they merely collect soot and prevent its combustion." This indicates the necessity of introducing the oxygen as close as possible to the fuel bed.

These investigators, however, seem to have been voices crying in the wilderness, for few boilermakers or operators have up to the present appreciated that secondary air may be used in anything approaching the volumes they indicate, and that it must, to produce the best effect, be impelled into the furnace in such a manner that it reaches those regions from which the combustible gases are rising.



"THE ENGINEER" SWAIN SC.

FIG. 3—*Flame Contour with Varying Percentages of Secondary Air.*

The time required for the air and combustible gases to diffuse together governs the length of the flame.

Rate of Heat Release per Unit Volume.—Referring again to Fig. 2, the authors have calculated the rate of heat liberation in the experimental furnace up to the point C where combustion is practically complete, and find this to be of the order of 120,000 B.Th.U. per cubic foot per hour.

In view of the fact that in the case of many furnaces in operation to-day it has been considered necessary to provide a sufficient volume to allow for a heat liberation rate of not more than 30,000 B.Th.U. per cubic foot per hour, it is clear that they are not as efficient as the experimental furnace used in Kreisinger's tests. There is not the slightest doubt that much higher rates of heat liberation in boiler furnaces are possible.

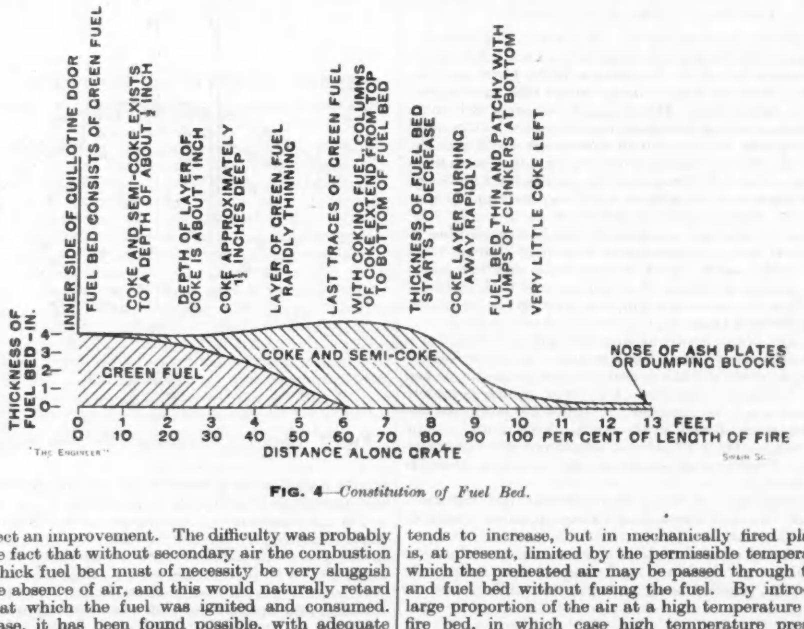
The degree to which the rate of combustion of a gaseous fuel may be accelerated by intimate mixing with the combustion air is demonstrated in the Hammond combustion unit. In this invention extremely intimate mixing is obtained by passing the air and fuel gas under a considerable pressure, through a labyrinth constructed of a large number of thin plates. By this means the air and gas are divided into an almost infinite number of fine streams, and the perfection with which they are diffused together renders possible combustion rates of the order of 20,000,000 B.Th.U. per cubic foot of combustion chamber space per hour. This rate of heat liberation is about 400 times as great as in the average high-duty boiler furnaces at the present time. The size and rating of the combustion chamber of a steam-generating unit is, therefore, a function of the secondary air admission arrangements and the degree of mixing which these arrangements produce.

Notwithstanding the difficulty of drawing oxygen through the fuel bed for combustion of the furnace gases secondary air was, as has been mentioned, seldom employed until the last year or two in large steam generator furnaces. Even so, it cannot be disputed that these installations worked, and are still working, comparatively satisfactorily as regards combustion. Their success depends on the maintenance of a comparatively thin fuel bed, and by burning it off prematurely the requisite secondary air can be obtained through the thinner part of the fire and brought into contact with the combustible gases by means of arches. In these installations, however, smoke is often troublesome, and a long flame, which often extends through the boiler into the superheater, is a feature of their operation. The large furnaces which are now being adopted are the outcome of the experience obtained with such installations.

During the last year the authors have given much attention to the applications of secondary air and find that, given a suitable arrangement, as much as 40 per cent. of the combustion air can be introduced above the fire without using any greater excess of air than was previously necessary; in fact, with installations equipped in this manner it has been possible to operate with a lower margin, as has been indicated by an increase in the CO_2 content up to 16 per cent. at the boiler outlet. This result is possibly due to the decrease in adventitious air due to the lower under-grate pressure necessary to pass the decreased volume against the resistance of the grate and the fuel. It is also found that when this method of operation has been applied to large combustion chambers the upper part is redundant and the flames which, without secondary air, had extended into the boiler passes and beyond, become shortened in the manner shown in Fig. 3, which gives the approximate contour of the flame with varying percentages of secondary air.

The arrangements for admitting the air in this installation are not ideal because of the tendency to project the flame towards the rear wall of the furnace, and to counteract this the authors consider that another row of jets should supply air from the rear and possibly from the sides of the furnace. The effect of injecting the air on all sides would be to create intense turbulence above the fire bed and to prevent the flames from impinging on the furnace walls.

It is generally agreed that in the case of chain grate stokers, as installed a few years ago, in which no secondary air was applied, it was impossible to burn off the coke when a fuel bed thicker than 4in. was used, no matter how much pressure was applied under the grate, and the doubt has been expressed as to whether secondary air would effect an improvement. The difficulty was probably due to the fact that without secondary air the combustion above a thick fuel bed must of necessity be very sluggish due to the absence of air, and this would naturally retard the rate at which the fuel was ignited and consumed. In any case, it has been found possible, with adequate secondary air properly applied, to use fuel beds of a depth more than double that hitherto considered the maximum.



"THE ENGINEER" SWAIN SC.

FIG. 4—*Constitution of Fuel Bed.*

Thus, efficient secondary air admission would appear to render unnecessary the large furnaces used to-day and would permit of much thicker fuel beds than have been previously adopted as a basis of stoker design. Hence, the width of stokers may be proportionately reduced, permitting the use of narrower boilers. This would, in turn, permit of much higher gas velocities being adopted in the convection tubes of the boiler and superheater, which would have an important influence on the heating surface required, as will be discussed later.

Effect of Thicker Fuel Beds.—It might be thought that any considerable increase in the fuel bed thickness above that commonly used would exert a damaging influence on the stoker and furnace walls, due to the increased rate of fuel burning that it would involve. The authors do not consider that there is any real ground for apprehension of such effects. With regard to the heating of the stoker a great amount of light has been shed on this most perplexing effect by some experiments by J. D. Maughan, described in a paper read before the Institute of Fuel by Dr. Grumell. From the observations he has recorded of the constitution of the fuel bed—see Fig. 4—and the corresponding grate temperatures, it is clear that the acquisition of heat by the grate occurs chiefly in the zone where the incandescent fuel is in contact with the grate surface. Similar conclusions have been reached by the authors, and these serve to show quite definitely the fallacy of the hitherto accepted idea that the heating of the grate is principally due to radiant heat from the furnace falling on the uncovered part of the grate surface at the rear of the stoker.

Other conditions being equal, it can be shown that the length of time during which a grate member is in contact with the incandescent coke is the same for any thickness of fire, but obviously the greater the thickness of the fuel bed, the lower is the rate of travel of the grate, from which it follows that the grate members are subject to this condition less often and so keep cooler, as has been found in practice.

Observations have been made of how the temperature of the grate entering the furnace varies with the speed, when operating with a constant fuel consumption, and of the variation in temperature of a grate member throughout the whole cycle, for two different speeds and with constant fuel consumption. From the results obtained it is clear that with a given rate of fuel consumption the grate temperature generally can be reduced by thickening the fuel bed and reducing the speed. By adopting suitable speeds and fire thicknesses, therefore, it appears quite possible to increase greatly the rating of the stoker and to maintain temperatures even lower than are encountered with the relatively thin fires and fast speeds which are at present in general use.

Regarding the effect on the furnace walls, it is admitted that the smaller the furnace the greater will be the intensity of radiant heat falling on a unit area of the wall surfaces. Therefore, an increase in the heat liberation rate certainly increases the severity of the temperature conditions which the walls have to withstand. The modern all-metal water-cooled wall is, however, in the authors' opinion, well able to withstand the conditions that such an increase in the combustion chamber rating would involve.

Apart from the advantages in reducing the size of the furnace described above, the efficient introduction of secondary air, by producing prompt and complete combustion, results in practically complete elimination of smoke. In such plants as can be considered to have an efficient secondary air equipment, the discharge from the stack is invisible. There appears also to be a marked decrease in the amount of grit, which may be due to a lower air velocity through the fuel bed.

Another important advantage gained by introducing a large percentage of the combustion air above the fire, which should not be overlooked, arises from the fact that it is thereby possible to utilise a greater quantity of heat in the combustion air without increasing the temperature of that passing through the grate. Considerations of economy in steam consumption in the modern power plant require that the feed water temperature is raised as high as possible by steam bled from the turbine before it is returned to the boiler unit, and, with advancing boiler pressures, the desirable feed temperature to the economiser rises accordingly. The duty of the air heater in reducing the gases to an economical stack temperature therefore tends to increase, but in mechanically fired plants this is, at present, limited by the permissible temperatures at which the preheated air may be passed through the grate and fuel bed without fusing the fuel. By introducing a large proportion of the air at a high temperature over the fire bed, in which case high temperature presents no objections, and by still limiting the under-grate air temperature to a safe figure, the total heat capacity of the combustion air may be substantially increased.

It appears, therefore, that by the closer observance of the principles of the process of heat liberation expounded above, an advance in the speed of operation may be made, together with a reduction in the size and cost of the stoker and furnace, and arising from this effect, a reduction in the size of the boiler may be contemplated.

(*To be continued.*)

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Steam Plant Accessories, Ltd., inform us that their address now is 59, Palace-street, Victoria-street, Westminster, S.W.1.

Lehmann, Archer and Lane, Ltd., announce that Mr. L. J. Gibson, late director of Peter Stubs, Ltd., has been appointed director and commercial manager.

Mr. H. M. Glass, who until recently was shipbuilding director of Barclay, Curle and Co., Ltd., is now associated with Harland and Wolff, Ltd., with headquarters at their London office, 9, Whitehall, S.W.1.

L. and C. Hardtmuth, lead pencil makers, are building a factory in England. British labour and British material will be used as far as possible, but the leads will continue to be made in Czecho-Slovakia; 80 per cent. of the material and labour will be British.

The Institution of Civil Engineers.—The Council of the Institution of Civil Engineers has awarded the Coopers Hill War Memorial Prize for 1932 to Mr. E. F. Reid, M.A., Assoc. M. Inst. C.E. (Oxford), for his paper on "Failures in Steel and Cast Iron Mains and Provision for their Protection." This prize was founded by the Coopers Hill Society in memory of Coopers Hill men who lost their lives in the war.

Mr. E. H. Wainford.—The death is announced of Mr. E. H. Wainford, who for upwards of thirty years was the North-Eastern representative of Thos. W. Ward, Ltd., Sheffield. A short time ago he relinquished part of his work, and was succeeded at the Middlesbrough office by his son, Mr. A. J. Wainford. Mr. Wainford was seventy-one years of age, and was well known in iron and steel circles in the North of England.

English Steel Corporation, Ltd.—At a board meeting of the English Steel Corporation, Ltd., held in London on November 16th, it was decided to spend approximately an additional £500,000 in continuation of the programme of reorganising and bringing up to date the extensive plant at the Vickers Works, Sheffield. We are informed that the money will be expended chiefly on the drop stamping plant at Sheffield, and on the extension of facilities for the heat-treatment of special steels. Provision is also made for the installation of one further open-hearth furnace in the new steel-melting house, completing a battery of four 60-ton furnaces.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The World's Steel Trade.

The improvement which has taken place in the situation of the British steel industry this year has not extended to foreign steel-producing countries. Whilst the growth of business in British steel materials was long overdue, the general trade position is weakened by the absence of any corresponding movement abroad, as this increases the danger of intensified competition for export orders. A notable feature of the world's situation is the dependence of nearly all steel industries upon their home market, and in many cases upon special Government plans for providing work. The British steel industry seems to be almost alone in its ability to make progress without reliance upon a doubtful policy of public work schemes. During the winter the German steel industry will depend largely upon orders arising from Government programmes, one of which, the enlargement of the Weser-Ems Canal, between the Ruhr and Bremen, will require about 100,000 tons of steel. Of the Continental industries, the French is probably the best employed, but of late there has been a shrinkage in the home demand which the public works programmes have failed to make up. The Belgian industry has probably suffered more than any other owing to its dependence upon export orders. Lately, the position seems to have improved, and the Belgian National Railway is about to issue orders for 200,000 steel sleepers. Nevertheless, the Belgian iron and steel production for the first nine months of 1933 shows an increase of from 6 per cent. to 8 per cent. over the corresponding period of last year The situation in the United States does not progress according to expectations, and production there has only reached 27·1 per cent. of capacity. The Americans also look to the Government for assistance, an instance being the advance of 84 million dollars to the Pennsylvania Railway for the purchase of electric locomotives and rolling stock. Over the steel trades of the world, however, hangs the danger of American competition, which, so far, has been chiefly confined to the lighter branches of the industry.

Current Business.

A FEW weeks before Christmas business in finished iron and steel materials begins to decline in volume, as most of the larger consumers have covered their requirements to the end of the year. Questions of stocktaking and end-of-the-year accounts have much to do with this tendency, which is a well-recognised feature of the trade. The strength of the present demand therefore is an indication of the satisfactory trend of business. Some good contracts have been placed lately, including one by the L.M.S. Railway Company for 2000 12-ton wagons, which have been distributed amongst the British steel works. The Russian Government has placed orders for 5000 tons of steel rails, which have been divided between Colvilles, Ltd., Dorman, Long and Co., and the North-West Coast works. The L.N.E.R. have also placed orders for a shed at Parkeston Quay with the Teesside Bridge and Engineering Company, Ltd., of Middlesbrough, and the G.W.R. have ordered coal-moving machinery from Vickers-Armstrong, Ltd., of Elswick. Glenfield and Kennedy, Ltd., of Kilmarnock, and Sir Wm. Arrol and Co., Ltd., of Glasgow, have secured contracts for the supply of sluice gates and steelwork for the Gebel Aulia Dam in Egypt, to the value of £70,000 and £55,000 respectively. It is understood that the former company will provide steel dam gates, whilst Sir Wm. Arrol and Co. will provide lock gates, capstans and pontoons. The Department of Overseas Trade announces that the following contracts are open for tender:—Argentine State Oilfields Department: rotary air compressor with a capacity for compressing 2000 cubic metres of free air per hour; also the supply of portable arc welding equipment and one grinding machine; to be presented in Buenos Aires by December 4th. South Africa, City of Cape Town: complete filtration plants for swimming baths; to be presented in South Africa by February 8th, 1934. Egyptian Ministry of Public Works: forty iron chains, 14·8 m. long, and thirty-six short link iron chains, varying from 6 m. to 13 m. long; to be presented in Egypt by December 10th. China: a local concern wishes to get into touch with United Kingdom manufacturers of plant for making reconstructed milk and cream. State Electricity Commission, Victoria: supply of control equipment for a 115-kW briquette press motor; to be presented by January 15th, 1934.

Pig Iron.

The position in this market has changed, and consumers are again showing interest in forward contracts. For some weeks past the tendency has been to purchase foundry iron in odd lots as they were required. The firm appearance of the market, however, has influenced sentiment, and it is probable that the caution shown by the producers in starting up new furnaces may also have had an effect upon buyers. On the North-East Coast in particular, although with the two furnaces put into commission last week the number at work is now twenty-one, only three are producing foundry iron. It was anticipated that more furnaces would have been put into operation on Cleveland iron some time ago, but it is reported that the makers are not finding it easy to ensure adequate supplies of furnace coke. It is not surprising, therefore, that consumers are negotiating for contracts up to March, and even beyond, as the stocks in makers' hands are practically exhausted. Most of the sales recently have been to Scottish and local consumers, and the Falkirk foundries appear to be increasing their output, and necessarily their requirements of pig iron. Local consumers are rather sore that the Scottish foundries can buy their iron at 62s. 3d. d/d Falkirk, which is 3d. per ton cheaper, in spite of the transport charges, than d/d Teesside. The Midland producers of foundry iron are also experiencing a good demand, but most of the makers in this district still carry substantial stocks, although these are being drawn upon. In these circumstances consumers are not so anxious to buy far forward; but neither are the producers eager sellers. It is taken for granted that any price movement will be in an upward direction, and this naturally turns the balance in favour of forward contracting when consumers can see their way clear. Scottish producers are not experiencing such satisfactory conditions as are the English; but the demand is steady. The output of the four furnaces making foundry iron is sufficient to meet the requirements of the market, but there is no export buying worth speaking of to help the moderate home demand. Business in basic iron in all districts at the new prices has not been active, as most consumers have contracts they can specify against. The steel works, however, are taking large quantities, chiefly from associated works.

Semi-finished Material.

The production of semi-finished steel is probably the most satisfactory feature of the British steel industry, and large as it is, it barely meets the requirements of the market. In fact, some consumers talk of delays in deliveries, and there is considerable difficulty in placing orders for measurably near delivery. Prices also, in spite of the recent advances, are becoming firmer, and the increase in the rate to £5 5s. for billets has merely strengthened the producers in their demand for premiums. Business can be done at £5 7s. 6d. in a few cases; but the general quotation is £5 10s. Continental works have followed the market up, but they are not offering large quantities for Great Britain. There does not seem much difference now between the prices asked for the British and the foreign material; in fact, some sellers of Continental billets claim they have sold above the British works price. It may be assumed either that these transactions were with consumers who required Thomas basic billets for special purposes, or that they indicate a stringency in some districts more acute than the market suspects. In the Midlands Continental sellers are quoting 2½in. and up at £5 9s., and 2in. and 2¼in. at £5 10s. d/d, including duty; but sellers claim on occasion to have obtained £5 11s. There is no doubt that the Continental makers vary their prices to the conditions ruling in different districts, and it has to be admitted that their policy of collective selling has enabled them to do this with advantage to themselves. For instance, in the Midlands the demand is chiefly for small billets, and their prices for these are higher than in other districts. In Scotland consumers have been quoted £4 17s. 6d. d/d, including duty, for large billets. The demand for sheet bars is not so strong as for billets, nor are prices so firm. At £5 d/d for sheet or tin-plate bars, the South Wales makers keep the local market in their own hands, but in some of the inland districts up to £5 7s. 6d. is asked for British material. The general price, however, is about £5 5s. Comparatively little business finds its way to the Continent, although it is probable that sellers would be prepared to accept £5 d/d, including duty.

The N.E. Coast and the Midlands.

The most important industrial event on the North-East Coast for some time is the restarting of the Acklam Steel Works by Dorman, Long and Co., Ltd. This follows the starting up of two blast-furnaces and two steel furnaces by the same firm, reported last week. The Acklam Works will be engaged upon the production of billets and sheet bars, and it is announced that sufficient orders are in hand to keep the mill employed until the end of the year, the production being about 4000 tons per week. Some fresh rail orders have been booked lately, including a contract for tramway rails for London. A fair number of constructional steel orders have come to hand recently, and although the shipbuilding industry is in a bad position, there has been an increase in the amount of ship-repairing work in hand. There is also a definite expansion of business in the Midlands, and a feature of the industrial revival in this district is the number of new factories being built and the extensions to existing works. This is reflected in a better demand for structural steel and reinforcing bars. There has been a significant movement towards placing contracts for forward delivery, which may be taken as an indication of consumers' fears that the present range of prices for controlled steel materials may be advanced. This is only natural since there has been a definite increase in the prices of re-rolled steel and uncontrolled descriptions. On the other hand, Continental quotations for the British market are higher at £6 17s. 6d. d/d Midlands for joists, as Continental prices have been slightly advanced on Exchange movements. In the case of small steel bars also there is a wide discrepancy between the British and Continental prices. Re-rollers are quoting for the most part £7 5s., and the steel works up to £8 10s., against a Continental figure of £6 10s. 6d. d/d, including duty. Re-rollers outside the district, however, are prepared to fight for a good order, and considering the margin in favour of the Continent, there is not a large tonnage of business going abroad. In South Wales tin-plate sales have not been on such a good scale as recently, and have dropped behind production. Prices have receded to 16s. 6d. to 16s. 9d. f.o.b., 20 by 14 basis. The shadow of American competition on the depreciated dollar has fallen on this trade; but so far there has been no contraction of output at the works.

Scotland, Lancashire, and the North.

Although a certain amount of the Scottish steel makers' plant is unemployed, indications point to a steady if rather gradual expansion. Recent shipbuilding orders will provide an outlet for a moderate tonnage of steel, and further inquiries are in circulation. The industry has also benefited by a large share of the L.M.S. contract for wagons, and about 1500 tons of the Russian order for rails will be manufactured by Colville's, Ltd. There has been talk recently of the help to the steel trade which the resumption of work on the Cunarder would provide; but when work on the vessel was suspended most of the heavy steel material had already been supplied. A fair tonnage of steel in the shape of sheets and other lighter sections, however, would be needed. In the direction of general business, the Scottish steel works are receiving moderate support, but the re-rollers are finding business difficult. Nevertheless, they are keeping their price at £7 5s. for home and £6 15s. for export. Conditions in the Lancashire area are improving slowly, and this applies to the constructional engineers, who, however, are depending upon a multiplicity of somewhat small orders rather than contracts which involve the use of good tonnages of steel. So far, the tendency noticeable in one or two other districts for consumers to place forward contracts for structural steel has not spread to Lancashire. Business in small steel bars has been on an extensive scale, and although many of the Lancashire re-rollers quote £7 10s., business has been done on the basis of £7 5s. Continental competition is not much felt in this market. A few orders have gone abroad recently, but many of the consumers are still able to specify against contracts placed weeks ago with British makers at lower prices than those now ruling. In the Sheffield and Yorkshire district the demand for stainless steel and alloy steel has strengthened, probably because buyers are becoming nervous lest the price advances on some ferro-alloys should force an increase in the prices of the steel in which they are used. The improved prospect of the steel industry in this district is indicated by the decision of the English Steel Corporation to spend £500,000 in improving its Sheffield plant.

A Survey of the Indian Market.

The Department of Overseas Trade has issued a comprehensive report on "Conditions and Prospects of United Kingdom Trade in India" in 1932–33, revised to July, 1933. The price is 3s. 8d. post free, from H.M. Stationery Office. In the section dealing with machinery and iron and steel it is pointed out that the downward movement of the imports of machinery from the high-water mark in 1928–29 has largely been checked. This is satisfactory, as the factors of intense depression in most Indian industries, the curtailment of Government purchases on account of severe financial stringency, and enforced reductions in extensions and renewals by public utility undertakings on the grounds of economy are still operating. Progress on new capital undertakings is also held up owing to the need for the rigid conservation of India's financial resources. The widespread nature of the depression is shown in the heavily reduced imports of boilers, prime movers, electrical machinery, and mining and general industrial plant. On the other hand, the remarkable expansion in the Indian sugar industry which followed the imposition of a high protective tariff has resulted in an advance of nearly £1,000,000 in the value of imports of sugar machinery. Of these imports Great Britain provided 70·2 per cent. in 1931–1932 and 74·1 per cent. in 1932–33, the remainder coming principally from the United States and Germany. The report points out that it is in times of stress such as the present that an efficient organisation on the spot secures such reduced trade as may be offering. In 1931–32 India imported 371,000 tons of iron and steel materials, of which the British share was 44·2 per cent., Belgium being next with 31·8 per cent., and Germany third with 26 per cent. In 1932–33 the total imports were 326,000 tons, of which Great Britain was credited with 43 per cent., Belgium with 31·9 per cent., and Germany with 22 per cent. The report remarks that, in spite of the depreciated sterling exchange, Belgian competition was severely felt in bars, structural sections, hoops and strip, steel sleepers and wire nails, where low price was the primary factor and B.S. specifications not insisted upon. In 1932–33 Luxemburg shipped 17,057 tons of steel bars, whilst Sweden and Norway supplied 1283 tons and 1529 tons respectively of nails, rivets, and washers. The United States was out of the market during the year, but French competition was met with in bars (4841 tons) and structural steel work (2675 tons).

Copper and Tin.

The fluctuations in the dollar exchange have overshadowed the electrolytic copper market and for a time buying by consumers almost ceased. This week, however, a slightly better tone has ruled, and the market recovered from about £32 10s., to which it had dropped, to £33 5s., c.i.f. The American producers continue to hold their domestic price at 8¼c., but buying has been poor. At times the Americans have been anxious sellers and have offered to sell for delivery over the whole of next year at current prices. This attitude marked a change in their policy, as until a few weeks ago they were reluctant to do business in sterling. In the London standard market prices were weak towards the close of last week, but recovered later, and there was a certain amount of covering. The movements of the dollar exchange, however, have been sufficiently erratic to discourage speculation in standard copper. . . . The tin market has shown more resistance to depressing conditions than other non-ferrous metal markets. There has been a fair amount of American buying, but the Continental demand still fails to expand. There is no doubt that the strength of the statistical position has been the principal reason for the firmness of tin prices, and there are expectations that the figures at the end of the month will show a further improvement and a substantial decrease in the visible supply. At the end of last week heavy sales of cash tin reduced the backwardation which had reached 25s., and it is now in the neighbourhood of 2s. 6d.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Anglo-French Trade.

The commercial relations between Great Britain and France have been profoundly modified by the system of compensating tax which the French imposed on British goods at the time sterling left gold and before even there could be any definite indication of the effect the depreciation of sterling would have on French manufacturing industries. The sales of British goods in this country had been rendered difficult and in some cases impossible by their much higher prices as compared with those of foreign competitive products. British manufacturers had the reputation of being too dear. The devaluation of sterling did little more than bring down British prices to a level with those of the German, for example, and for the first time British importers saw the possibility of doing business more in harmony with the heavy purchases that were made by Great Britain in France. The compensating tax of 15 per cent. levied on the total cost of British goods imported into France checked this promised expansion of trade. It was also intended to influence Great Britain in stabilising the pound on a gold basis. The immediate effect of the tax was to create a feeling of resentment in Great Britain against what appeared, at the outset, to be a discriminating measure that was contrary to the spirit of the existing treaty of commerce, and all subsequent attempts of the French to negotiate a new commercial treaty have been met by the obligation imposed upon them to suppress the compensating tax. At the time of the London Conference the French Government was disposed to make this concession, and it could not, in fact, logically justify the maintenance of the tax when sterling had settled down to its real level and had shown itself to be the most stable of all currencies. Industrial interests in France, however, opposed the suppression, and commercial interests regarded the removal of the tax as contingent on Great Britain offering compensating advantages; this, too, despite the obvious peril in which it has placed the French exporting industries. British purchases in France have been largely diverted to other channels, while the French are mainly dependent upon Great Britain for supplies of raw material, partly in transit through British ports, and the balance of trade which was considerably in favour of France has now been reversed to her growing disadvantage. People in this country are fully alive to the danger of the situation. Events have of late developed rapidly, and efforts are being made to retrieve the consequences of the various fiscal measures which have had the effect of provoking retaliation from other countries. There has been a lack of method throughout in dealing with the trade situation, and measures have been improvised by various Governments in order to meet more or less temporary conditions. The present Government has taken the matter in hand and is credited with having evolved a plan of organisation which aims, first, at the completion of negotiations that have been continued intermittently with Great Britain since the London Conference. The decision of Great Britain to denounce the agreement with France whereby the two countries undertook to refrain from adopting discriminating tariff measures towards each other is regarded as a serious matter. It is supposed that the British Government contemplates action in view of the refusal of the French to remove the compensating tax. Monsieur Laurent Eynac, Minister of Commerce, was therefore delegated to London this week to discuss the matter with Mr. Runciman. It is difficult to see how such a discussion can be profitable in view of the fact that Great Britain refuses to recognise the principle of the tax, the discriminating character of which is emphasised by its not being applied to the depreciated dollar. There can obviously be no question of Great Britain paying for the suppression of the tax by means of concessions to the French. It may therefore be assumed that Monsieur Laurent Eynac was prepared to discuss difficulties that stand in the way of negotiations for a treaty of commerce under conditions that will be of equal advantage to the two countries.

Free Ports.

The leading port authorities have for many years endeavoured to secure the passing of a Bill for the creation of free zones around them in which factories could be installed for working up materials imported into the zones duty free for export. It was argued that the arrangement would benefit merchant shipping and facilitate export trade, but when the Bill was presented to the Chamber of Deputies last week it was opposed on the ground that the institution of free zones around ports would be a hazardous experiment in present circumstances, for, apart from the huge cost of creating Customs barriers, the freedom granted to foreign shipping would be detrimental to home shipping, which would no longer enjoy a monopoly of the colonial carrying trade, and that, moreover, it would be impossible to suppress frauds. The agricultural interest also opposed the Bill. It was rejected on a preliminary vote without further debate.

Bridge Builders' Responsibility.

Two years ago a suspension bridge at Saint-Denis-de-Pile, in the Gironde, collapsed while being tested under load and several persons lost their lives. The platform broke away from the suspension rods. The bridge was constructed by a firm to the order of the Departmental authorities, and the question of responsibility for the disaster came up for the consideration of the Prefecture of the Gironde, which has now given its judgment, in which it states that the Departmental authorities have some responsibility arising out of the fact that the losses sustained by the public through the accident were the result of work carried out in the public interest; but, on the other hand, the responsibility of the builders only ceased when the bridge had passed the tests and was handed over to the authorities. In these circumstances the authorities and the builders are held jointly responsible for claims for damages arising out of the accident.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

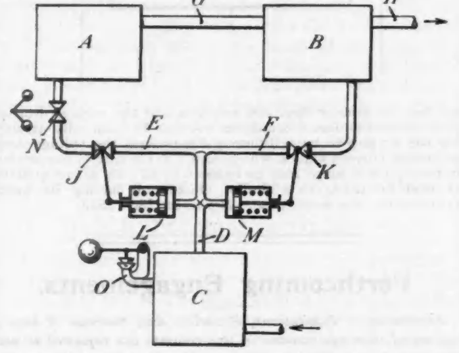
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

399,755. May 24th, 1933.—Steam Power Installations, Sulzer Frères Société Anonyme, Winterthur, Switzerland.

Steam is required at a high pressure in the apparatus A and at a lower pressure by B. It is supplied by the generator C through the main pipe D and branch pipes E and F. Steam from the high-pressure set A exhausts through the pipe G to B and finally at H. Valves J and K are arranged in the pipes E and F, and are actuated by pistons L and M. These pistons work against springs that are so calibrated that A takes steam alone up to a predetermined pressure, but if the pressure in the generator should rise higher, on account of the closing of the governor N, steam will go to the low-pressure unit B *viâ* F. In this way the safety valve O is prevented from lifting with a drop in the load.—*October 12th*, 1933.

Nº 399,755

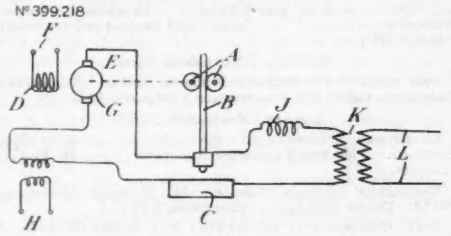


DYNAMOS AND MOTORS.

399,218. April 1st, 1932.—Systems of Electric Motor Control, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2.*

The improved system of motor control described in this specification is particularly suited for controlling the motor employed for operating the feeding mechanism of an automatic arc welding machine. The feed mechanism comprises rolls A arranged to feed the electrode B towards the work C. It is assumed that the stator D of the motor E is fed from supply conductors F at a fixed voltage. The rotor G is fed by a variable tension resulting from the vector component of the tension at the terminals of the arc, and a tension supplied by the secondary of a small auxiliary transformer H, the primary of which is also fed by the network. The arc circuit includes a reactance J and the secondary of a supply transformer K fed from the supply L. By means of a suitable selection of the various constants, the stator and rotor currents are in quadrature for a certain value of the tension at the terminals of the arc. The couple is then nil at the tension which corresponds to a particular length of the arc. It is evident that numerous variations are practicable, especially if the tension of the feed to the stator is obtained, for instance, from another phase than that which feeds the arc.—*October 2nd*, 1933.

Nº 399,218

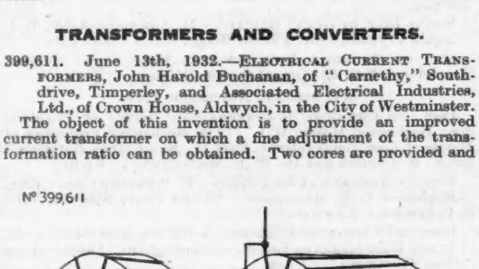


TRANSFORMERS AND CONVERTERS.

399,611. June 13th, 1932.—Electrical Current Transformers, John Harold Buchanan, of "Carnethy," South-drive, Timperley, and Associated Electrical Industries, Ltd., of Crown House, Aldwych, in the City of Westminster.

The object of this invention is to provide an improved current transformer on which a fine adjustment of the transformation ratio can be obtained. Two cores are provided and interlinked with a common primary circuit, which may comprise a single primary winding or separate primary windings connected in series with each other, and a secondary winding on one core is connected serially with a secondary winding on the other core directly, *i.e.*, without the inclusion of any additional impedance, across a tertiary winding on one of the cores. By the direct connection of the windings as described, a fixed relation between the fluxes in the cores on the one hand, and a fixed division of current between the tertiary winding and the secondary windings on the other hand, are assured. The serially connected secondary windings may be connected additively or otherwise. With this arrangement, while a coarse adjustment of the transformation ratio of the transformer can be made by varying the number of turns of the secondary winding on either or both of the cores, a relatively finer adjustment of the transformation ratio can be effected by varying the number of turns of the tertiary winding across which the serially related secondary winding on the respective cores are connected. Preferably the arrangement is designed so that the cores remain unsaturated within the normal working range of current loading of the transformer. In this manner, both cores are fully utilised under all working conditions of current loading, so that the effect is secured of a determinate mean permeability at all loads in spite of the fact that the two cores may have permeability curves differing from one another. The cores may be constructed of materials which differ in respect of their magnetic permeabilities for a given range of magnetising force.—*October 12th*, 1933.

Nº 399,611



FURNACES.

399,708. February 18th, 1933.—Electrical Resistance Furnaces, Société Anonyme des Manufactures des Glaces et Produits Chimiques de St.-Gobain, Chauny and Cirey, of 1 bis Place des Saussaies, Paris, France.

In the existing resistance furnaces the resistance is secured at both ends in members connected to the poles of the source of electrical energy, with the result that the stresses due to the expansion of the resistance act on the turns of the helix and frequently cause them to fracture. The objects of the invention are to remedy this inconvenience and to strengthen the resistance. The invention provides a resistance comprising two closely spaced coaxial graphite heating elements, one of which is tubular or prismatic, and the other helical. In the drawing, A is the shaped resistance, screwed at one end into a terminal block B by means of a plug C and, at the other end, into the interior of a tube D, which is coaxial with the resistance and is itself screwed into a terminal sleeve E. The resistance A, tube D, and plug C are of graphite. The members B and E are of amorphous carbon and carry metallic current leads F and G. The relative spacing of the resistance A and block B on the one hand, and of the tube D and sleeve E on the other, is adjusted by means of movable screws H engaging in lugs secured to the member E, the screws bearing against insulating members J. The furnace is completed by means of a ring K connected to the sleeve E by means of tie rods (not shown). The space between the ring K and sleeve E is occupied by heat-insulating material L retained by an insulating shell M and a metal sheath N.—*October 12th*, 1933.

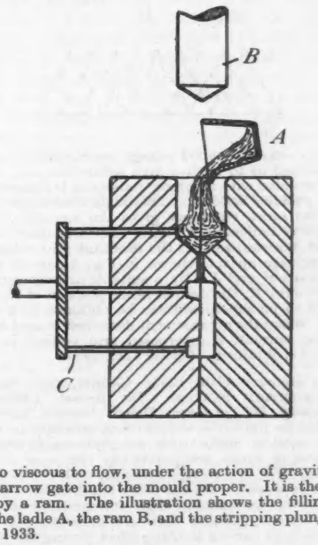
MACHINE TOOLS AND SHOP APPLIANCES.

399,389. February 24th, 1933.—Die Casting, G. J. Weissenberg, No. 11, Tegastrasse, Berlin-Mariendorf, Germany.

This invention is concerned with the die casting of articles in metals having a comparatively high melting temperature. The metal is poured into a head in the mould at such a temperature that it is too viscous to flow, under the action of gravity alone, through a narrow gate into the mould proper. It is then forced into place by a ram. The illustration shows the filling of the head from the ladle A, the ram B, and the stripping plungers C.—*October 5th*, 1933.

Nº 399,389



MOTOR CARS AND ROAD TRAFFIC.

399,181. March 29th, 1932.—Electric Circuit Breakers, Joseph Lucas, Ltd., of Great King-street, Birmingham; and Ernest Owen Turner, of the same address.

The object of this invention is to provide an improved automatic circuit breaker adapted for use more particularly in the electrical equipments of motor vehicles, the device being of the type in which the automatic opening of the switch under abnormal conditions is dependent upon the fusion of a metal bond. In the event of an excessive current passing through the heating coil A the heat generated is sufficient to melt the fusible metal bond B. The movable disc C can then return automatically to the "off" position under the action of the springs D acting on the operating member E, the control plate F remaining held by the retaining projections G. After interruption of the current the coil quickly cools and the fusible metal solidifies, thereby re-establishing the bond between the control plate and the rotatable switch member and enabling the switch to be operated again in the normal manner. The fixed contacts are shown at H and the movable contacts at J. The part K is secured to the control plate F formed with a pair of equidistant holes, any opposite pair of which can engage the rounded projections G on the base under the action of the spring L. The extent to which the disc C can be rotated is limited by the stop M. The rotatable contact disc C can be actuated by a detachable key N.—*September 29th*, 1933.

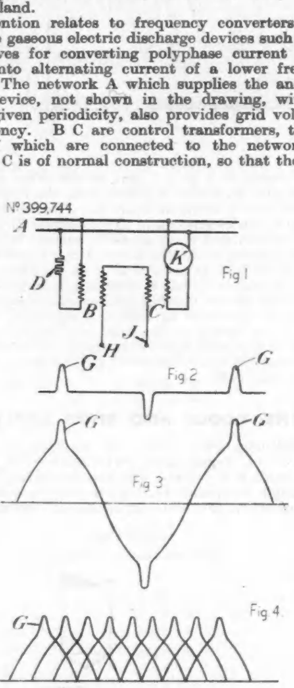
MISCELLANEOUS.

399,744. April 28th, 1933.—CURRENT FREQUENCY CHANGERS EMPLOYING GRID-CONTROLLED DISCHARGE DEVICES, Aktiengesellschaft Brown, Boveri et Cie., of Baden, Switzerland.

This invention relates to frequency converters employing low-pressure gaseous electric discharge devices such as mercury vapour valves for converting polyphase current of a given frequency into alternating current of a lower frequency, or *vice versâ*. The network A which supplies the anodes of the discharge device, not shown in the drawing, with working voltage of given periodicity, also provides grid voltage of the same frequency. B C are control transformers, the primary windings of which are connected to the network A. The transformer C is of normal construction, so that the secondary winding gives a sine-shaped voltage curve, while the transformer B is so wound as to receive high saturation and, at the same time, is provided with an ohmic resistance D connected in series with the primary winding. This highly saturated transformer B with the series resistance gives the secondary voltage the form of curve indicated in Fig. 2. The secondary windings are connected in series, so that the resultant grid voltage with the pointed voltage apex G shown in Fig. 3 can be taken off at the terminals H and J. By a suitable arrangement such as a phase advancer K, the desired phase position of the two curves which are to be superposed can be obtained in a very simple manner. When the arrangement described is used for six-phase alternating current, a superposed grid voltage in accordance with Fig. 4 is obtained.—*October 12th*, 1933.

No 399,744



399,058. January 17th, 1933.—CHOKE COILS FOR ELECTRIC DISTRIBUTION SYSTEMS, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2.*

In order to limit the short-circuit currents in high-tension systems, coreless choke coils are commonly used, the self-inductances of which are practically the same at all current intensities. For low-voltage systems, such choke coils become large and expensive. On the other hand, choke coils with iron cores have an undesirably high voltage drop when carrying normal currents, because their self-inductance is determined by the required current-limiting effect during the short circuit, and the self-inductance for normal currents increases to a multiple of that for short-circuit currents, owing to the lower iron saturation. The object of the invention is to remove these disadvantages. Two coils A and B are arranged on different limbs of an iron core C, and are connected in series in opposite sense. In the iron core within each coil there is an air gap which is dimensioned according to the conditions, and can also be adjustably arranged by displacing one of the yokes. The operating current may be assumed to flow through the coils at a certain moment in the directions indicated by the arrows, and when the current is normal there is a resultant field in the iron due to the two coils which, as the coils are connected in opposite sense, is only slightly different from zero. Since the leakage is also small in the case of normal current, the resulting self-inductance of the choke coil, measured at the terminals, and thus the inductive potential drop, is only small. If the current increases the leakage also increases, and finally becomes so great in the case of currents of short-circuit nature that the two coils may be regarded as individual or separate choke coils. Their effect is then practically the same as if they were separate and connected in series. The following data have been obtained by experiment:—A choke coil with coils connected in the same sense, and which limits the short-circuit currents at 220 volts to 500 ampères, shows at a normal current of 10 ampères a voltage drop of more than 20 volts. If the two coils, however, are connected in opposite sense, the short-circuit current does not become greater than 500 ampères, but the voltage drop at normal current does not amount even to 10 volts. By arranging the air gap to have different dimensions, the voltage drop at normal current values, which occurs in the case of connection in the opposite sense, may be reduced to as little as one-quarter of that occurring in a similar choke coil having its parts connected in the same sense.—*September 28th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

TO-DAY.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN STUDENTS.—Armstrong College, Newcastle-upon-Tyne. "Precision Alternating-current Measurements," Mr. M. Waters. 7.15 p.m.

INST. OF STRUCTURAL ENGINEERS: MIDLAND COUNTIES.—At James Watt Memorial Inst., Birmingham. "Designing for Welding," Mr. C. Helsby. 7 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Refrigerating Machines and their Applications," Mr. W. S. Douglas. 7.30 p.m.

MANCHESTER ASSOC. OF ENGINEERS.—At Engineers' Club, Manchester. "The Technique of Heavy Forging," Capt. R. Benson. 7.15 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. Discourse, "Liquid Crystals," Sir William Bragg, F.R.S. 9 p.m.

SOC. OF CHEMICAL INDUSTRY: FOOD GROUP.—At British Medical Assoc., Tavistock-square, W.C.1. Symposium, "Bread and Milk." 10 a.m. and 2.30 p.m. Trocadero Restaurant, Shaftesbury-avenue, W.1. Dinner and cabaret entertainment. 7.15 for 7.30 p.m.

SATURDAY, NOVEMBER 25TH.

INST. OF CIVIL ENGINEERS.—Students' visit to Erith works of Callender's Cable and Construction Company, Ltd.

MONDAY, NOVEMBER 27TH.

BRADFORD ENGINEERING SOC.—At Technical College, Bradford. "Modern Pyrometer Apparatus," Mr. H. Pickard. 7.30 p.m.

ENGINEERS' GERMAN CIRCLE.—At Holborn Restaurant, W.C.1. Dinner and dance. Reception, 7.30 p.m.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN CENTRE.—At Armstrong College, Newcastle-upon-Tyne. "Application of Automatic Voltage and Switch Control to Electrical Distribution Systems," Messrs. W. Kidd and J. L. Carr. 7 p.m.

ROYAL SOC. OF ARTS.—John-street, Adelphi, W.C.2. Cantor Lecture, "Colour Block Prints," Lecture II., Mr. Hesketh Hubbard. 8 p.m.

TUESDAY, NOVEMBER 28TH.

INST. OF ELECTRICAL ENGINEERS: SCOTTISH CENTRE.—Grosvenor Restaurant, Gordon-street, Glasgow, C.2. Annual dinner and ladies' evening. 6.30 p.m. for 7 p.m.

INST. OF PRODUCTION ENGINEERS: YORKSHIRE SECTION.—Hotel Metropole, Leeds. Discussion on "Estimating Methods." 7.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. "Liquid Crystals," Sir William Bragg, F.R.S. 5.15 p.m.

SOC. OF CHEMICAL INDUSTRY.—At Hotel Great Central, Marylebone, N.W.1. Annual chemical dinner.

WEDNESDAY, NOVEMBER 29TH.

INST. OF CHEMICAL ENGINEERS.—In Rooms of Chemical Soc., Burlington House, W.1. "The Mechanical Properties of Metals at Low Temperatures, Part II., Non-ferrous Materials," Mr. E. W. Colbeck and Dr. W. E. MacGillivray. 6 p.m.

INST. OF MECHANICAL ENGINEERS: N. WESTERN GRADUATES.—Engineers' Club, Manchester. "Tidal Power Schemes," Mr. J. L. Morden. 7.15 p.m.

INST. OF PRODUCTION ENGINEERS: BIRMINGHAM GRADUATES.—James Watt Memorial Institute, Birmingham. Discussion on "Heat Treatment." 7 p.m.

THURSDAY, NOVEMBER 30TH.

INST. OF CIVIL ENGINEERS: YORKSHIRE ASSOC.—Hotel Metropole, Leeds. Short paper by students for discussion. "Tramway Reconstruction," Mr. C. R. Warman: "An Economic Aspect of Reinforced Concrete," Mr. E. A. Dyer. 7.30 p.m.

INST. OF LOCOMOTIVE ENGINEERS.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. Informal meeting. Mr. O. Bulleid will open discussion on "The Most Suitable Form of Traction for Main Line Railway Operation." 6 p.m.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—In James Watt Memorial Inst., Birmingham. "Symposium on Defects in Cold Working," arranged by Mr. A. L. Molineaux. 7 p.m.

FRIDAY, DECEMBER 1ST.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Thomas Lowe Gray Lecture, "High-speed Diesel Engines for Marine Service," Mr. H. R. Ricardo, F.R.S. 6 p.m.

INST. OF SANITARY ENGINEERS.—At Abercorn Rooms, Great Eastern Hotel, Liverpool-street, E.C.2. Annual dinner. 6.45 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Dairy Machinery and Plant," Mr. W. Chopping. 7.30 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS.—In Mining Inst., Newcastle-upon-Tyne. "The Electric Welded Ship 'Peter G. Campbell,'" Mr. N. M. Hunter. 6.p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1.—Discourse by Mr. R. M. Chambers. 9 p.m.

SATURDAY, DECEMBER 2ND.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN STUDENTS.—Joint visit with graduates of N.E. Coast Inst. of Engineers and Shipbuilders to the Pelaw Main Collieries coal-washing plant at Wrekenton.

STEPHENSON LOCOMOTIVE SOC. (MIDLANDS).—At Crumpsall Library, Manchester. "The Liverpool Overhead Railway. 6.30 p.m.

MONDAY, DECEMBER 4TH, TO FRIDAY, DECEMBER 8TH.

SMITHFIELD CLUB SHOW.—At Royal Agricultural Hall, Islington, N.1. 9 a.m. daily.

MONDAY, DECEMBER 4TH.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN CENTRE.—Rendezvous Restaurant, Pilgrim-street, Newcastle-upon-Tyne. Informal meeting. Discussion, "Electricity as a Heating and Warming Agent," opener Mr. L. E. Mold. 7 p.m.

SOC. OF CHEMICAL INDUSTRY.—Burlington House, W.1. "The Control and Measurement of the Temperature in an Industrial Laboratory," Messrs. E. A. Cooke and J. C. Swallow. 8 p.m.

TUESDAY, DECEMBER 5TH.

CHADWICK PUBLIC LECTURES.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Rural Sanitation," Mr. J. H. Coste. 8 p.m.

CHELSEA POLYTECHNIC.—Manresa-road, S.W.3. Distribution of prizes, diplomas, and certificates to students by the Viscount Leverhulme. 8.30 p.m.

INST. OF ELECTRICAL ENGINEERS: SCOTTISH CENTRE.—At N. British Station Hotel, Edinburgh. Dinner, 6.30 for 6.45. Prof. F. G. Baily will introduce a talk, "Reminiscences of Early Days."

INST. OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.—39, Elmbank-crescent, Glasgow, C.2. "Shipyard Methods and Lay-outs," Mr. G. Barrie. 7.30 p.m.

WEDNESDAY, DECEMBER 6TH.

INST. OF MECHANICAL ENGINEERS: N. WESTERN BRANCH.—(Joint meeting with the Liverpool Engineering Soc., Liverpool.) Thomas Lowe Gray Lecture, "High-speed Diesel Engines for Marine Service," Mr. H. R. Ricardo, F.R.S. 7.15 p.m.

THURSDAY, DECEMBER 7TH.

INST. OF MECHANICAL ENGINEERS: N. WESTERN.—Engineers' Club, Manchester. "Factors Affecting the Grip of Force, Shrink and Expansion Fits," Mr. R. Russell. 7.15 p.m.

INST. OF STRUCTURAL ENGINEERS: YORKSHIRE BRANCH.—Hotel Metropole, Leeds. "Properties of Concrete—A Summary of Present-day Information," Mr. J. Singleton-Green. 7 p.m.

FRIDAY, DECEMBER 8TH.

INST. OF ELECTRICAL ENGINEERS: S. MIDLAND STUDENTS.—Boots' Café, Colmore-row, Birmingham. Annual dance.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Informal meeting. Discussion, introduced by Mr. A. Perry-Keene, "Shop Organisation." 7 p.m.

RAILWAY CLUB.—57, Fetter-lane, E.C.4. "Signalling, Remote Control," Mr. Edward Wallis. 7.30 p.m.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

VICKERS-ARMSTRONGS, Ltd., Elswick Works, Newcastle-on-Tyne, have received a further order from the Great Western Railway Company for equipping ten hydraulic coal hoists in South Wales ports with the "Norfolk" spade for the quick clearing of small coal from railway wagons.

THE L.M.S. RAILWAY COMPANY announces the placing of orders for the construction of 2000 new freight wagons on renewal account, in order to provide for the extension of the company's policy of running an increased number of express freight trains. All these wagons will be of the 12-tons open type for conveying general merchandise, and will be fitted with the continuous brake to enable them to be used in high-speed freight trains. Four hundred of them will be built in the company's own workshops, and the remainder have been ordered in equal proportions from the following firms:—Birmingham Railway Carriage and Wagon Company, Ltd.; Metropolitan Cammell Carriage Wagon and Finance Company, Ltd.; Charles Roberts and Co., Ltd., Horbury Junction (Yorkshire); Hurst Nelson and Co., Ltd., Glasgow. An important feature of the new wagons is that they will be fitted with underframes constructed wholly of British steel.

THE ENGLISH ELECTRIC COMPANY has received a contract from the Leeds Corporation covering switchgear and transformers for the Whingate sub-station, comprising a 24-panel, 6600-volt, metal-clad switchboard of 350,000 kVA rupturing capacity, and four 6000-kVA, three-phase power transformers, with remote-controlled on-load tap-changing gear. In addition, the contract covers a number of 11-kV oil-immersed isolators, a four-pillar metal-clad switchboard with neutral earthing, a cubicle type control board, and auxiliary apparatus, such as battery, battery board, motor generator set, oil filtering plant, &c. The value of this contract is in the neighbourhood of £34,000. The same company has received an order from the Kettering Urban District Council for 33,000-volt and 11,000-volt switchgear necessary for the new station giving the electric supply to the New Mill of Stewarts and Lloyds at Corby. This contract includes a 33,000-volt outdoor type sub-station controlling transformer and feeders with switchgear of 500,000-kVA rupturing capacity, remote controlled, together with structures, foundation work, fencing, flood lighting, &c.; and a 7-unit, 11,000-volt metal-clad switchboard, having a rupturing capacity of 250,000 kVA, together with auxiliary switchgear for lighting and heating, &c. In parallel with the order for Kettering Urban District Council, the company has also received a contract from Stewarts and Lloyds, Ltd., for the 11,000-volt metal-clad switchgear required for the New Mill at Corby. This contract covers some thirty-five units in all for installation in seven sub-stations. This gear will have a rupturing capacity of 250,000 kVA. Stewarts and Lloyds, Ltd., have also awarded the English Electric Company a contract for sixteen transformer units. The value of the latter three contracts is approximately £33,000.

L.N.E.R. MAIN LINE OIL-ELECTRIC LOCOMOTIVE.—We are asked to state that the rotary exhauster for the above-named locomotive described in our issue of November 17th, was supplied through the Consolidated Brake Company and was manufactured by Reavell and Co., Ltd., Ipswich.

A Seven-Day Journal

The Value of Naval Work.

IN the course of a speech made at the annual general meeting of the Fairfield Shipbuilding and Engineering Company, Ltd., held at Govan, Glasgow, on Friday last, November 24th, Sir Alexander Kennedy, the chairman and managing director of the company, said that in view of the long-continued and severe depression, the company had every reason to be satisfied with the result of the year's working, which had enabled a small credit balance to be carried forward. Sir Alexander referred to the naval work which had been entrusted to the company by the Admiralty, and commented on the definite improvement in the outlook with regard to merchant shipbuilding. He stressed, however, the importance of Admiralty work, which, he said, might best be appreciated when one remembered that one cruiser of, say, 9000 tons displacement, was at least equal in value to twenty vessels of about 8000 tons deadweight carrying capacity, and that at least 85 per cent. of the cost of such a vessl was spent in wages. The Admiralty had done a good deal in the last few years to assist the shipbuilding industry, and he felt that more would have been done but for Government restrictions. An adequate Navy was essential for the defence of this country and the Dominions, but there was another point which he thought should weigh with the Government. In times of merchant shipbuilding depression, naval programmes should, he held, be anticipated in order to advance technical skill and maintain skilled workmen in regular employment. Our high position in industry depended on the skill of our craftsmen, and skill acquired by continued application would render an invaluable aid to industrial development.

A New Grid Tariff.

THE Central Electricity Board has notified authorised undertakers in the North-West England and North Wales area of the introduction of a "grid" tariff to become operative on January 1st, 1934. Particulars of the tariff for the South-East England and East England areas were given in our issue of November 3rd, and it will suffice to call attention to the figures, which differ from those in that tariff. As regards the service charge there is no change, but the fixed kilowatt charges in respect of each point of supply are £3 7s. 6d., £3 3s., £2 18s. 6d., and £2 14s., the progressive reduction of the kilowatt charge being made as the demand of an undertaking increases in the manner now familiar to supply engineers. There is no change in respect of variations of the fixed charge with power factor. The paragraph covering the variation governed by rates shows that the fixed kilowatt charge is increased or reduced at the rate of 1s. 10d. for each shilling above or below 4s. arrived at by the usual method. For each kilowatt supplied and taken during the year the sum of 0·2d. is to be paid, and if the usual coal cost calculation gives a sum of more or less than 15s., the running charge will be increased or reduced in the year by 0·0009d. for each penny by which the sum is above or below 15s., As before, a halfpenny or any greater part of a penny is treated as a penny, whilst in the case of the rates variation of the fixed charge a *pro rata* increase or reduction is made for any part of one shilling.

A London Trollybus Scheme.

THE London Passenger Transport Board announces that during the present session of Parliament it will promote a Bill for the conversion of certain tramway routes in London to trollybus operation. The proposed routes represent about one-quarter of the total miles of tramway track in London, and will increase the present 18 miles of trollybus traction by some 90 miles. Most of the routes chosen for conversion are in the outer areas and they comprise the route from Hammersmith to Hounslow and Uxbridge, Hanwell to Brentford, Acton to Canons Park and Paddington to Sudbury. A new terminus near Tottenham Court-road will be arranged for the trollybus services from Euston to the northern areas, while the southern routes will include those from Woolwich to Dartford, Woolwich to Bexley Heath, and the Crystal Palace to Sutton. The latest type of trollybus will be employed, with a seating capacity of seventy-four, compared with sixty-four for the latest type of tramway vehicles. No decision has been announced with regard to the disposal of the discarded tramway vehicles, but it is felt by the Board that a large number of them are definitely nearing the end of their useful lives.

New Shipbuilding Orders.

THE month of November has seen important additions made to the order books of British shipbuilding firms, and within the past week a number of new orders have to be recorded. The Admiralty has entrusted to the Fairfield Shipbuilding and Engineering Company, Ltd., the building and equipping of the coastal sloop "Kingfisher," belonging to the 1933 naval programme. At the neighbouring Govan yard of Harland and Wolff, Ltd., construction will shortly be begun on a 515ft., 13,000-ton, 16-knot, refrigerated cargo motor vessel for the Shaw, Savill and Albion Company, Ltd., of London. Two sister ships are being built at the Belfast yard of Harland and Wolff, Ltd. Other Clyde orders include three welded shallow draught motor vessels for Irrawaddy Flotilla service, which are to be built by William Denny and Brothers, Ltd., at Dumbarton. The Anglo-Saxon Petroleum Company, Ltd., of London, has placed orders for twelve large motor tankers, four of which will be built in Great Britain, three in Holland, three in Germany, and one each in Italy and Denmark. They will all be of 12,100 tons deadweight carrying capacity, with a length of about 465ft. and a beam of 60ft., and will each be propelled by a single 4000 B.H.P., eight-cylinder oil engine having cylinders 650 mm. by 1400 mm. Both hulls and machinery will be built to the owner's special specification. The four British orders have been placed with Lithgows, Ltd., of Port Glasgow; Workman, Clark (1928), Ltd., of Belfast; Harland and Wolff, Ltd., of Govan; and Swan, Hunter and Wigham Richardson, Ltd., of Wallsend-on-Tyne. The engines for the Lithgow and Swan Hunter hulls are to be supplied by John G. Kincaid and Co., Ltd., of Port Glasgow, and Hawthorn, Leslie and Co., Ltd., of Newcastle-upon-Tyne, respectively. Orders for three steamers have been placed by Cory Colliers, Limited, of London, with the Wear shipbuilding firm of S. P. Austin and Son, Limited. The engines will be built at Sunderland by the North-Eastern Marine Engineering Co., Ltd.

L.M.S. Locomotive Orders.

CONSIDERABLE satisfaction is felt in the British locomotive industry by the announcement that the London, Midland and Scottish Railway Company has placed with locomotive building firms orders for one hundred locomotives and tenders for express passenger and goods trains. The Vulcan Foundry will build fifty 4-6-0 superheater two-cylinder engines for mixed traffic; and the North British Locomotive Co., Ltd., fifty 4-6-0 superheater three-cylinder engines for passenger traffic. In the case of the Vulcan Foundry about 400 men have recently been employed, and it is anticipated that it will now be possible to find employment for about 1600 additional men, the work occupying about nine months. The Scottish order will likewise bring about an increase in the number of workers employed both at Springburn and in auxiliary trades. Further employment in the railway rolling stock industry has been created at the Motherwell works of Hurst, Nelson and Co., Ltd., which firm has secured part of the order for 2000 12-ton wagons for the London, Midland and Scottish Railway Company, which was briefly referred to in last week's Market Notes on current business.

Rural Water Supplies.

SPEAKING in the House of Commons on Monday evening, November 27th, Sir E. Hilton Young, the Minister of Health, announced that the Chancellor of the Exchequer had agreed to put at his disposal the sum of £1,000,000, which would be used towards the capital cost of water schemes in rural areas to be prepared and initiated in the next few years. A Bill will shortly be introduced in connection with the scheme. It was essential, the Minister continued, that the local authorities and the consumers of water should bear their proportion of the cost, but the Exchequer grant would be used to mitigate the local burden. The provision of Government assistance in that matter was no indication of the weakening of the Government's general policy of abstention from any form of unremunerative schemes. Water schemes, he held, stood on their own basis of merits as essential for the public health. It was estimated that the capital sum of one million pounds, utilised in the way indicated, would help the promotion of schemes and break the back of a very difficult problem. He was confident that the Government's decision would be welcomed as a real contribution to that problem.

Empire Communication.

THE ninth annual Norman Lockyer Lecture was delivered by Professor E. V. Appleton in the hall of the Goldsmiths' Company on Thursday, November 23rd, the subject being Empire Communication. It was no exaggeration to assert, the lecturer explained, that the whole history of communication by both cable and wireless had been stimulated by Imperial requirements. The first two great pioneer achievements in long-distance communication were concerned with the linkage of Great Britain with her oldest Colony, Newfoundland. The commercial short-wave beam stations, which now linked up the Motherland with India and the Dominions, constituted an unparalleled system of efficient and inexpensive point-to-point communication, while the Rugby long-wave telegraph station of the Post Office gave a service of nearly twenty-four hours a day to all parts of the world. During the last few years direct wireless telephone services to different parts of the Empire had been established by the Post Office, the beam senders and directional receivers being used with corresponding stations overseas. The sending stations were all accommodated at Rugby, while the corresponding receiving stations were at Baldock. The result of these Empire services was that the whole of the Empire was on the telephone, with London as the exchange. A man in the Australian bush could communicate with another out on the veldt in South Africa *via* Rugby and London. By way of the Transatlantic route such outlying districts could be linked up with the whole of the United States and Canada. London was the world's switching centre, and Rugby its relay station. An American tourist out in Egypt would speak to his home in Philadelphia, not directly to the United States, but *viâ* the British Egyptian service through Baldock, London and Rugby.

Southern Railway Electrification.

THE Southern Railway, which already has the largest suburban electrified system in the world, has decided to extend its electrified lines to Sevenoaks, Kent. The extension will be from Chislehurst and Orpington and will add 23 route miles to the electric system, at a cost of over £500,000. Needless to say, the third rail direct-current system will be employed. The stations affected are Orpington, Chelsfield, Knockholt, Dunton Green, Sevenoaks (Tubs Hill), St. Mary Cray, Swanley Junction, Eynsford, Shoreham, Otford, and Sevenoaks (Bat and Ball). Trains will consist of eleven three-car motor units and four two-car trailer units. The new electric services will be supplementary to the existing main line trains and the number of trains serving the various stations will be increased to the extent of 86 per cent. to 209 per cent. The service to Sevenoaks (Tubs Hill) *viâ* Swanley will be an extension of the existing service from Holborn Viaduct to Shortlands *viâ* the Catford loop. Three three-car trains will run every hour between Charing Cross and Sevenoaks *viâ* Swanley Junction on weekdays and two trains per hour on Sundays. During the busiest periods the trains between Swanley Junction and London will consist of eight car sets. The service between Sevenoaks and Charing Cross *viâ* Chelsfield will be a continuation of the existing service between Charing Cross and Orpington and will consist of three trains per hour on weekdays and two trains per hour on Sundays. During the rush hours trains between Charing Cross and Orpington will consist of eight-car sets, which will be broken down at Orpington and will continue as three-car sets between that station and Sevenoaks.

Southampton Port Approaches.

FOR some time past the Southampton Harbour Board has been in touch with the Elder Brethren of Trinity House with regard to much-needed aids to the navigation of the approaches to Southampton Harbour, which area, however, falls outside its jurisdiction. On Tuesday afternoon, November 28th, at a meeting of the Harbour Board, a letter was read from the Elder Brethren stating that Trinity House would be prepared to give favourable consideration to a scheme for the establishment of a radio beacon at the Nab Lighthouse, provided that the Harbour Board would make a substantial contribution towards the first cost and maintenance. The first cost is estimated at £2000 and the maintenance at £200 per annum. The Works and Harbour Committee of the Board reported that the radio beacon at the Nab Lighthouse was an absolute necessity and suggested that the range of the beacon should be extended to 30 or 35 miles, so that both entrances to Southampton Water would be served. The Committee recommended the Board to pay a contribution of £1000 towards the cost, but to inform Trinity House that it could not undertake any payment for maintenance. The Board has just spent some £3000 on the improvement of the Fawley beacon.

The French Liner L'Atlantique.

IN a Journal note of September 1st we outlined the difficult problem presented by the burnt-out hull of the liner "L'Atlantique," which her owners had abandoned as useless, and the underwriters had refused to take charge of, except for repairs. In order to get over the difficulty presented, the Seine Commercial Court appointed three experts to re-examine the hull and propelling machinery and to report on the possibility of repairing them and reconditioning the liner. The experts' report was made known on Friday last, November 24th, and it is understood that by a majority of two to one it was decided that the ship could not be repaired. The experts are further of the unanimous opinion that the cost of repairs would exceed in any case the 100 million francs provided by the all-risks policy. If the Court confirms the findings of the experts, then the owners will not only be entitled to recover the 100 million francs above referred to, but also a further 70 million francs covered by the total loss insurance. As the greater part of the insurance was effected, either directly or by reinsurance, with British underwriters, the position is a serious one, both for the underwriter and for the shipbuilder, who might repair the liner. The suggestion that a compromise may be reached between the owners and the underwriters is denied by Monsieur Leopold Dor, who is acting for the Compagnie Sud-Atlantique, who has stated that the law will take its course, and that the case will likely come up for hearing before the end of the year.

Recent Hydro-Electric Power Plants in Sweden.

No. IV.

(Concluded from page 512, November 24th.)

OTHER POWER STATIONS ON THE INDAL RIVER.

SOME brief mention should be made of the utilisation of the waters of the Indal River for the generation of electric energy in two plants which are already in operation. The most important of these is the Hammarforsen dam and hydro-electric plant. The development of the Hammarforsen waterfall on the Indal River began in 1925 and the hydro-electric station commenced operation in 1928. The plant, which is owned by the Hammarforsen Power Company, is the largest of an extended system of interconnected and co-operating generating plants supplying power to a number of important industries in the area between the Angerman River in the north and the Ljusnan and the Hamrange River in the south. Another plant, completed this year, is that at Sillre, on the Oxsjöan, a tributary of the Indal River, where storage plant has been installed by which water is pumped from the Indal River to Lake Oxsjön, 197 m. above it. We hereunder describe this interesting plant.

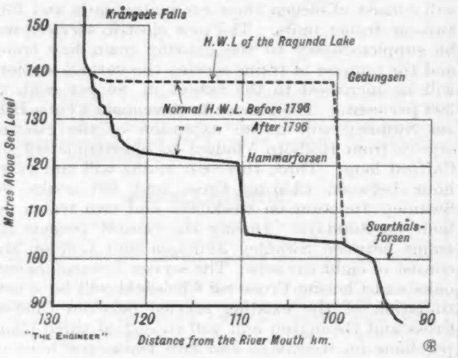

FIG. 31—LONGITUDINAL PROFILE OF THE GEDUNGSEN AND HAMMARFORSEN FALLS

The Hammarforsen is a remarkable waterfall in so far as it is, geologically speaking, the youngest fall in Sweden. Before 1796 there was, at the site of the present falls, a large lake, the Ragunda Lake, which had its outlet through the Gedungsen rapids of about 35 m. height. The water level of the lake then stood about 18 m. above the present water level upstream of Hammarforsen. In 1790 the digging of a small canal, through a ridge of sands and gravels to the right of the Gedungsen rapids, was begun by a logging company, with the object of providing a convenient passage for the timber past the rapids. When the work had advanced so far that the water of the lake began to discharge through the canal, a heavy scour took place in the glacial material of the canal bed during a high flood, and on June 6th, 1796, a catastrophe happened. In a few hours the lake surface was lowered about 35 m. and an immense volume of water flowed down the valley of the Indal River, causing considerable damage. The scouring continued upstream from Gedungsen, but about the middle of the old Ragunda Lake the waters passed over a ledge of rock, which traverses the valley at right angles to the direction of the stream, forming a new waterfall, the Hammarforsen. At the place where the great Gedungsen fall once foamed there is now only the "Dead Fall" to remind one of the catastrophe (Fig. 31).

FIG. 32—HAMMARFORSEN POWER PLANT—SECTION THROUGH POWER-HOUSE

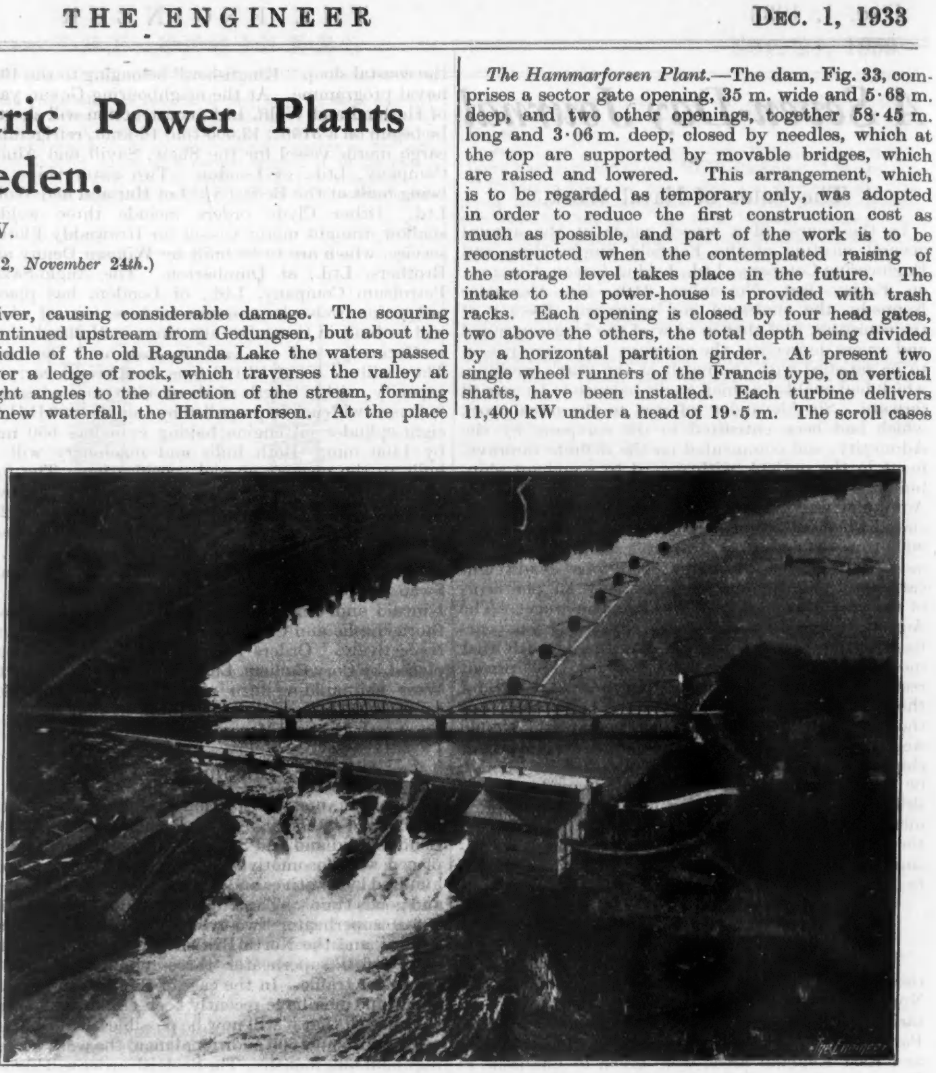

FIG. 33—AERIAL VIEW OF HAMMARFORSEN STATION

The Indal River rises in the mountains along the Norwegian frontier, flows to the east and south-east and discharges its waters into the Gulf of Bothnia.

The following are particulars of the flow in the river at Hammarforsen, which is some 18 kiloms. below Krangede:—

Catchment area..	24,000 sq. kiloms.
Flood water flow	Up to 2,500 cu. m. per sec.
Mean flow	400 " "
Flow during 50 per cent. of the year	260 " "
Flow during 75 per cent. of the year	142 " "
Ordinary minimum flow	91 " "
Head at the Hammarforsen power station	19·5 m.

The possibilities for regulating the flow are good. The low water flow can be increased to about 250 cubic metres per second by means of storage in the large natural lakes in the upper reaches of the Indal River.

The Hammarforsen Plant.—The dam, Fig. 33, comprises a sector gate opening, 35 m. wide and 5·68 m. deep, and two other openings, together 58·45 m. long and 3·06 m. deep, closed by needles, which at the top are supported by movable bridges, which are raised and lowered. This arrangement, which is to be regarded as temporary only, was adopted in order to reduce the first construction cost as much as possible, and part of the work is to be reconstructed when the contemplated raising of the storage level takes place in the future. The intake to the power-house is provided with trash racks. Each opening is closed by four head gates, two above the others, the total depth being divided by a horizontal partition girder. At present two single wheel runners of the Francis type, on vertical shafts, have been installed. Each turbine delivers 11,400 kW under a head of 19·5 m. The scroll cases are made of reinforced concrete, which is remarkable under this head. The generators are rated at 12,000 kVA, 6000–6600 volts, 50 cycles, and 93·8 r.p.m. The ultimate capacity of the plant will be about 50,000 kW. In view of this, the forebay is at present bounded by a temporary wooden dam. The space between the generator hall and the intake contains the transformers and switchgear. The total annual output of the plant in recent years has amounted to 95 million kWh. Two views of the Hammarforsen power station and falls are reproduced in Fig. 33 above and Fig. 42 on page 548.

FIG. 34—MAP OF HAMMARFORSEN POWER SUPPLY AREA

COFFERDAMS.

The cofferdams used for the construction of the Hammarforsen dam and power station are of great interest and are typical of the practice now generally adopted in Sweden in the construction of such works in turbulent water. The cofferdams are indicated in plan in Fig. 35 and were all constructed on the solid rock. Most of the work was carried out in the rapids, whose velocity was as high as 15ft. to 20ft. per second. The choice of methods of construction was limited by the circumstances of the situation. Watertight earth material was not available within a reasonable distance from the site; it was therefore out of the question to employ cofferdams with earth filling or in which earth was required for the purpose of obtaining water-tightness. The use of timber cribs, filled with stone, was considered as affording a comparatively simple means of building cofferdams in a rapid flowing stream. The adoption of this type of dam would reduce the risk of accidents and damage to a minimum, but it had the drawback that a relatively long period would be required for demolition on completion of the permanent works. Cofferdams of the trestle type, common in Sweden, are most suitable for rivers whose velocity is not high and they possess the great advantage of being quickly and easily removed. Their construction in turbulent rapids is, however, a matter of difficulty, and there is more trouble in making them water-tight than is encountered with timber cribs. The steeply sloping bed of the river at the Hammarforsen Falls rendered it possible to design all the cofferdams in such a way that leakage water could be run off on the downstream side of the work, thus avoiding to a great extent the necessity of pumping.

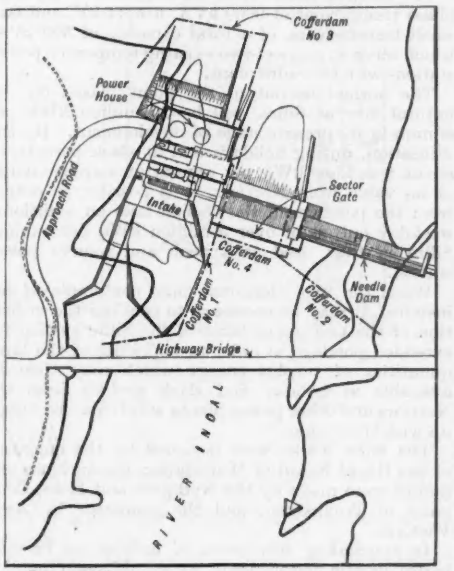

FIG. 35—PLAN SHOWING POSITION OF COFFERDAMS

The cofferdam (No. 1) surrounding the intake and power station was designed to withstand water pressure during high floods, and as delay in removing the temporary works around this part of the permanent structure was a matter of minor importance, timber crib construction was employed in building it. On the other hand, cofferdam No. 3, for the tailrace, was built in comparatively calm water, and as it was of importance to remove it as soon as possible after the completion of the permanent works, the trestle type of construction was employed. The cofferdams for the construction of the permanent dam had to be built in that part of the river where the velocity was very great; but, as they would be used only during the low-water periods which, in the Indal River, occur in winter, and as they had to be removed before the coming of the spring floods, it was decided to build them of the trestle type.

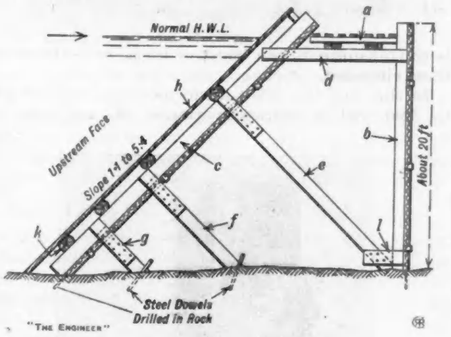

FIG. 36—CROSS-SECTION OF TRESTLE TYPE COFFERDAM

In the case of the timber crib dam No. 1, substantial water-tightness was obtained by the use of a single sheeting of vertically placed 2in. planks on the upstream side, the planks at their lower ends being shaped according to the contour of the rock surface. Jute material was nailed on to these planks to reduce leakage to a minimum, and only where the rock was very uneven was it necessary to have recourse to a second layer of short planks near the rock surface. The height of the crib dam on the average was a little more than 17ft. and the greatest water pressure occurred during the spring flood of 1926 and was equivalent to a head of 17ft. The height of this flood was practically the same as that of the greatest flood in the Indal River recorded for many years. A view of the crib dam, showing the enclosure for the construction of the power station in the background, taken during this flood, is reproduced on page 548. The river discharge at this time was about 2200 cubic metres per second. A view of the cofferdam is also reproduced in Fig. 44.

Timber trestle dams can be built without any great difficulty up to a depth of 13ft. to 15ft. by men experienced in this class of work. When, however, the depth exceeds this limit the increased velocity of flow through the partially completed structure caused by the damming of the river results in such vibration that uprights (or "soldiers"), which are round timbers of about 12in. diameter, are snapped off before the struts can be put into position. This occurred at Hammarforsen. As timber of a larger diameter was not available at a reasonable price and a change of design substituting rolled steel joists for timber would have caused delay in building the cofferdam, as well as considerable modification of the arrangements already made for building it, the difficulty was overcome by building two protection dams, or screens, which are seen in the photograph reproduced in Fig. 45. These were built out into the river alternately with the main cofferdam, one screen on each side of the latter. They were of the trestle type, but no attempt was made to make them water-tight. By this arrangement the water pressure was distributed and the velocity reduced, so that the vibration of the "soldiers," when placed in position, and before they were supported by braces, was greatly reduced. The screens also facilitated the work of completing and making water-tight the cofferdams proper. After these were finished the screens were removed.

A cross section of one of the trestle dams is shown in Fig. 36. The cofferdam was built from the stage or gangway *a*, which was successively cantilevered from the part of the trestle already completed. The steel dowel rod for the downstream "soldier" *b* and that for the front "soldier" *c* were first bored for and fixed in the rock, after which the two "soldiers" were placed in position and connected by the strut *d*. Following this the strut *e* was placed, the lower end of which was slid along the downstream "soldier" *b* by means of the plates *l* forming a fork. It was not until the downstream water level had been lowered by placing the planks *h* in position and thereby reducing the velocity of the water that the struts *f* and *g* could be erected. The horizontal runners *k* were spiked above water level in sections or panels to two of the vertical planks, and in this way the whole section could be lowered in one piece by sliding it down the face of the front "soldiers." The struts were fastened to the rock and prevented from slipping by steel drill bars inserted in holes bored in the rock. When the velocity and depth of the water was not too great this boring was done from above water level by ordinary compressed air tools with steel rods of 1¼in. to 1½in. diameter, but when the depth and velocity made this method difficult the boring was carried on inside steel tubes.

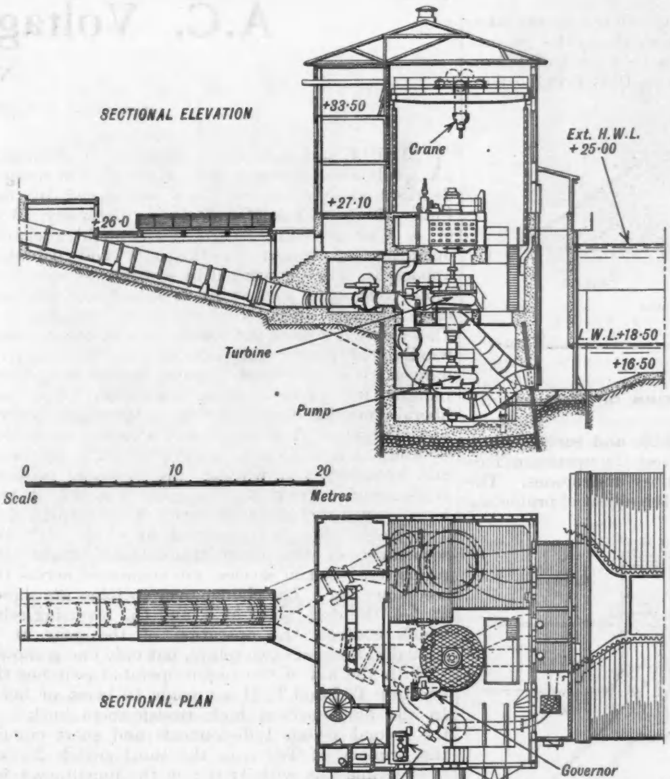

FIG. 37—SILLRE POWER STATION—CROSS-SECTION AND PLAN

Very little diving work was required in the construction of the trestle dams at Hammarforsen. Divers were employed only for a small amount of filling and tightening between the plank sheeting and the rock and at the corners of the cofferdams.

Fig. 43 is a view of the completion of the last cofferdam for the permanent dam, and Fig. 46 shows the removal of the trestles after the completion of the permanent work, an operation which was performed rapidly by means of derrick cranes. The greatest height of the trestle cofferdam, measured from the rock to the crest of the planking, was about 20ft., and the maximum head of water to which the dam was exposed was 18ft.

The consulting engineers for the Hammarforsen works have been Vattenbyggnadsbyran (V.B.B.), of Stockholm, under the supervision of whose engineer-in-chief, Mr. Erik W. Jonson, the construction of the cofferdams was carried out.

The Hammarforsen Supply Area.—The network of the Hammarforsen Company comprises:—One 70,000-volt line, Hammarforsen–Granlo; one 40,000-volt line, Granlo–Harnösand; and one 70,000-volt line, Granlo–Kinstaby, a place north of Bergvik, where connection to the system of the Bergvik and Ala Nya Company is established. The Hammarforsen system is also connected to that of the Arbra Power Company, and indirectly, through the network of the Kramfors Company, to the system of the Norrfors hydro-electric state plant. By this means a most useful exchange of energy is rendered possible within a vast area covering about 500 kiloms. from Robertsfors in the north to Vifors in the south. The Hammarforsen transmission system supplies power to the towns of Harnösand, Sundsvall, and Söderhamn, but the principal consumers are the numerous pulp industries and saw mills in the industrial districts between the Angerman River and the Hamrange River.

In Fig. 34 we reproduce a map* of the Hammarforsen power supply area which shows very clearly the extent of this important co-operative system. It should be noted that the scale indication of the Krangede plant in this plan is that of the first section of two units now under construction.

THE SILLRE POWER PLANT.

The State hydro-electric power plant at Sillre was put into operation in April, 1933. It supplies electric energy over a 70,000-volt line, at present operated at 40,000 volts, to the consumers of the Norrfors power group, and is complementary to the Norrfors hydro-electric station. During 1932 the energy generated at Norrfors amounted to 145 million kWh, the bulk of which was supplied to the numerous saw mills, sulphate and sulphite factories, and pulp mills in the coastal region between Sundsvall and Umea on the Gulf of Bothnia. In order to utilise the surplus energy of the Norrfors plant during holidays and at other slack periods, the Sillre plant has been equipped with a pump for raising water from the Indalsälven through the penstock and the head-race tunnel up to a storage reservoir—the Oxsjön lake—which has its natural discharge through the Oxsjöan, or Sillre, a small tributary to the Indalsälven—plan, Fig. 39.

The plant, although of comparatively small dimensions, is of particular interest as it operates on a head of water greater than any hitherto employed in Sweden, and is the first pump-storage installation in that country.

On a plateau north of the Indalsälven, about 60 kiloms. from the outlet of the river to the Gulf of Bothnia, there is situated a lake system including three lakes of moderate size—Oxsjön (3·5 square kilometres), Storvallsjön (3·3 square kilometres), and Storskälsjön (9·7 square kilometres). The head between Oxsjön and the Indalsälven is about 190m., and the difference in level between the lakes is about 22m. in each case, Storskälsjön being 22m. above Storvallsjön and 44m. above Oxsjön. The lakes have steep banks so that regulation is comparatively simple, and the cost of raising the water levels is small.

---

* From "Hydro-Electric Development in Sweden," E. Upmark, Swedish Water Power Association, 1933.

The following are the hydrographic data of the Oxsjön stream at the outlet from the lake :—

Catchment area	220 sq. kiloms.
Lakes included in catchment area ..	20 ,,
Minimum natural flow	0·5 cu. m. per sec.
Mean flow	1·7 ,, ,,
Maximum flow	15·0 ,, ,,
Gross head after regulation..	185·5 m. to 197·5 m.

The three regulated lakes—Oxsjön, Storvallsjön, and Storskälsjön—have storage capacities of 20, 4·6, and 14·5 million cubic metres respectively, or about 40 million cubic metres, which is more than the total flow of a dry year.

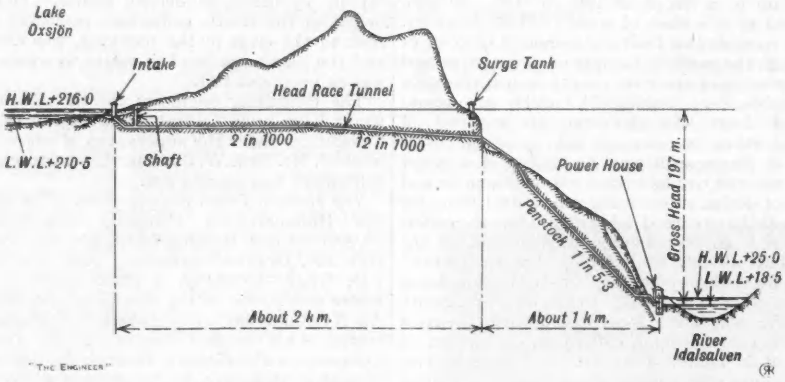

FIG. 38—DIAGRAMMATIC SECTION OF SILLRE HYDRO-ELECTRIC POWER PLANT

Dam.—By means of a rock-fill dam, 280 m. long and 8 m. high (Fig. 40) the level of the lowest lake, the Oxsjön, has been raised 4 m. above the original level. The lake can be drawn to a level of 1·5 m. below the latter, the total draw thus being 5·5 m.

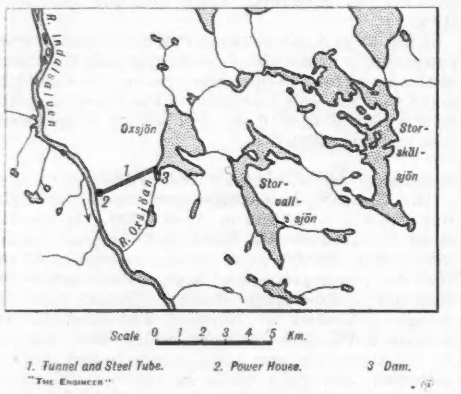

FIG. 39—SILLRE—SITUATION PLAN

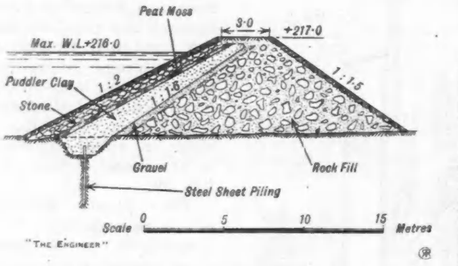

FIG. 40—CROSS-SECTION OF DAM

The dam consists of rock rubble and earth with a water-tight covering of clay on its upstream face protected by a blanket of moss and stones. The moss blanket is provided with the object of protecting the clay from extremes of temperature when the water is run down.

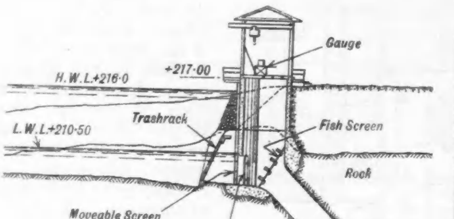

FIG. 41—INTAKE ON LAKE OXSJON—CROSS-SECTION

Intake, Tunnel, &c.—After passing through an intake, constructed on the lake side (Fig. 41) the water is carried through an almost horizontal head-race tunnel, 2 kiloms. in length, through the hill which separates the Oxsjön lake from the Indalsälven valley (Fig. 38). The tunnel has a cross section of 5 square metres, is entirely in rock, and no lining is provided. At the lower end of the tunnel is a circular, vertical surge shaft, 8 m. diameter, which permits of a range in water level of about 27 m. The steel penstock, 1·85 m. diameter, joins the head-race tunnel and is provided with a butterfly valve and an air valve. The upper part of the penstock tube is laid in an open cutting and is lined with concrete and covered with earth. The greater part of the penstock is, however, laid in an inclined tunnel blasted in the rock, and the space between the rock and the steel is filled with concrete. The plate thickness is only 6 mm., which necessitates a combined resistance of steel and rock to the water pressure. Close to the power-house the penstock is free and is carried on concrete cradles ; the plate thickness is here increased to 22 mm.

Power Station.—The power station (Fig. 37) is built on the east bank of the Indalsälven. At present one unit only, viz., No. 2, of 6300 kW, is installed. Ultimately, the plant will comprise three turbines and generators of 2500, 6300, and 8000 kW respectively, the second and third units each having a pump on the same shaft as the generator and turbine. The second unit, which is now in operation, comprises :

(*a*) A single-wheel, vertical-shaft Francis turbine (9333 H.P.) for 6300 kW at 6000 r.p.m. and 190 m. head.

(*b*) A three-phase generator, direct-coupled to the turbine, rated at 7000 kVA, 6000-7000 volts, 50 cycles.

(*c*) A centrifugal pump, of a capacity of 2·5 cubic metres per second at 190 m. head, coupled to the same shaft as the generator and the turbine and below the latter. When pumping the generator is run as a motor and fed with energy from the Norrfors hydro-electric plant.

The maximum discharge of the turbine at 100 per cent. gate opening and 190 m. head is 4·1 cubic metres per second.

The outdoor transformer station includes a three-phase transformer of 9000 kVA, 6·6/44 kV, and two small transformers, of a total capacity of 300 kVA, which serve to connect two existing temporary power stations with the Sillre plant.

The normal output of the plant, based on the natural flow at Sillre, will be 20 million kWh per annum in its present stage of development. By the utilisation, during holidays and at slack periods, of about 9 million kWh per annum of surplus energy of no value from Norrfors, it is possible to obtain from the pondage in the Oxsjön lake an additional weekday output of over 5 million kWh per annum. Sillre is thus used as a peak and reserve power station.

When the two additional units contemplated are installed, it may be necessary to consider the utilisation of the two upper lakes of the Sillre system for extended pondage in order to make use of the large quantities of surplus energy which may then be available at holiday and slack periods from the Norrfors and other power plants which may be linked up with the system.

The Sillre works were designed by the engineers of the Royal Board of Waterfalls ; the turbines and pumps were made by the Nydquist and Holm Company of Trollhättan, and the generator by Asea, Västeras.

In concluding this series of articles on Swedish hydro-electric power plants, we should again mention our indebtedness to Lieut.-Colonel A. Ekwall for permission to publish the description of the Vargon and Sillre works, and to Mr. Gottfried Berg, of Vattenbyggnadsbyran, consulting engineers, Stockholm, for similar permission in the case of the Krangede and Hammarforsen power plants. These gentlemen, their respective staffs, and Mr. B. Hellstrom, assisted us in every possible way when we recently visited these interesting works, and to them and also to the makers of the turbines and electrical machinery our thanks are due for the use of plans and photographs.

A.C. Voltage Regulators.

No. II.

(Continued from page 514, November 24th.)

A SIMPLE and inexpensive regulator for comparatively small outputs and for use on low-tension distribution systems has been introduced by the Fuller Electrical and Manufacturing Company, Ltd., of 5, Chancery-lane, W.C.2. Thoroughly reliable operation is claimed for this new and patented apparatus, which is worked by a disc-type induction motor driving a lead screw arranged to open and close spring-loaded switches, shown in Fig. 11. These switches alter the connections of the primary windings of booster transformers, and, consequently, only carry a very small current, whilst the power required for operating them is also low. They are liberally rated and contact wear is, therefore, reduced to a minimum. As the regulator is usually controlled by voltage, it takes care of the pressure at all times, and irrespective of whether the incoming pressure is constant. From the diagram, Fig. 12, it will be perceived that the secondaries of the transformers Tr I and Tr II are connected in series with the secondary of the main transformer, whilst the primaries, when in service, are connected across the secondary line. The change-over switches are shown at 1–4, the disc motor at 5, and the reversing relay which controls the operation of the gear at 6. Actually, there are two relays, but only one is shown.

With the aid of the motor-operated switches the boosters Tr I and Tr II are made to boost or buck. In the first position both transformers buck ; in the second switch 1 disconnects and short circuits the primary of Tr I ; in the third switch 2 deals in the same way with Tr II ; in the fourth, switch 3 reverses the primary of Tr I and causes it to be energised so as to make it give a boost, and finally, switch 5 alters the connections of the primary of Tr II in a like way, and also causes it to boost. By means of the switches 1–4, the primaries are thus made to buck, are short circuited, or are caused to give a boost as required to suit the load conditions according to the adjustment by the voltage-controlled relay operating in the motor circuit. With the switches in the position shown in Fig. 11, the first transformer is boosting and the second is having no effect on the pressure at all. At other switch positions both transformers can boost or buck, or both can be short circuited.

In this way the two transformers can be arranged to deal with a voltage variation of, say, plus or minus 4 per cent. in steps of 2 per cent. each, and by adding more transformers and switches any reasonable number of steps can be obtained. The

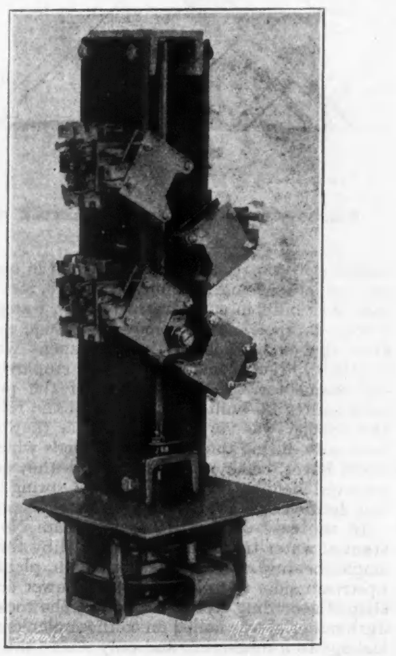

FIG. 11—SWITCHES AND OPERATING MOTOR

motor is controlled by a reversing relay actuated by a voltage-control relay—Fig. 13—which is very sensitive. It consists mainly of an electro-magnet, and a potential coil upon an induction vane of copper moves in the magnet air gap. At the opposite end of the arm there is another copper vane which serves to damp the arm movement. When the voltage varies the vane moves in the field of the electro-magnet, and this movement is utilised to operate the motor-starting and reversing relay. A special device in the voltage-control relay, which is both sensitive and robust, ensures quick breaking at the contacts.

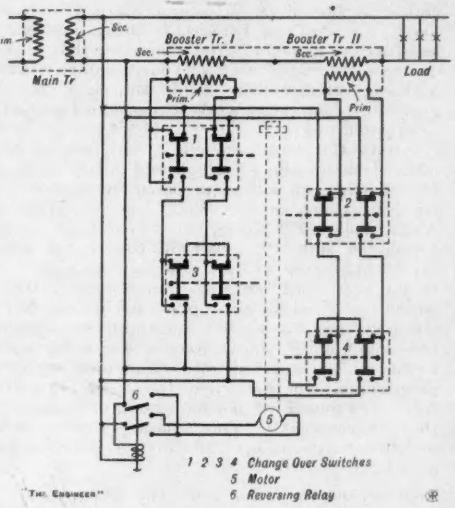

Fig. 12—Connections for Fuller Regulator

Normally, the complete equipment is contained in a single tank, divided into two compartments, one for the transformer, and the other for the switch mechanism and relays. Time delay is obtained by suitable spacing of the pivot arms operating the switches from the revolving lead screw, so that the regulator only operates on a definite drop and does not endeavour to follow any fluctuations of short or momentary duration. The regulator can be designed for indoor or outdoor service, and, if necessary, for erection on poles. It is employed on 400/440-volt or higher pressure single or three-phase feeders, and it is made in sizes up to about 250 kVA.

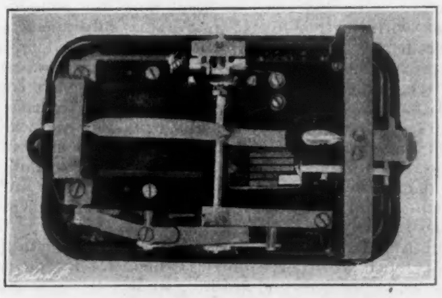

Fig. 13—Voltage Control Relay

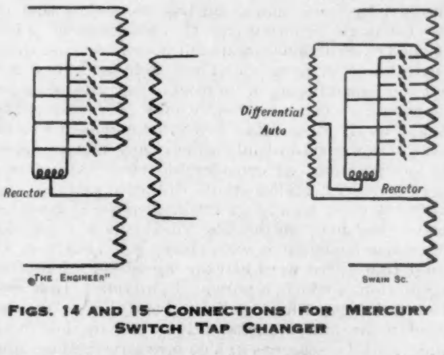
Mercury Switch Tap-changing Regulators.

On load tap-changing gear, suitable for distribution transformers has been developed by Ferranti, Ltd. Like the switches used on the tail end booster those associated with this gear are of the mercury type and are oil-immersed. As the gear forms a unit with the transformer, no tapping leads or switch connections have to be brought outside the tank. Another advantage is that the power required to tilt these switches is very small. No doubt there are still some engineers who regard the use of switches composed of glass and mercury as poor heavy-engineering practice, but exhaustive tests are said to have proved that there is really nothing to fear. The standard rating of a mercury switch as specified by the makers is, however, no guide to its capacity for tap-changing work. When used in conjunction with this apparatus they must be capable of withstanding the most severe short-circuit currents that can arise.



Figs. 14 and 15—Connections for Mercury Switch Tap Changer

The short-circuit carrying and breaking capacities of the switch are, therefore, measured, and the safe full-load current is determined from the values obtained. To take a typical example, the normal full-load winding current of a 500 kVA, 11 kV distribution transformer is 15·2 ampères. The mercury switches used with this transformer have a tested short-circuit carrying capacity of 400 ampères, or over twenty-six times the full-load current. They also have a tested breaking capacity of at least 280 ampères at 150 volts at low lagging power factor. Although under short circuit the current may be considerably greater than normal, the voltage to be dealt with will be correspondingly below normal, so that these tests in which both current and voltage were increased are to be regarded as very severe. The mechanical gear has also been designed to ensure that it will not operate on a short-circuit current greater than four or five times full load due to a voltage drop. Life tests on individual switches, involving up to 2,000,000 breaks of full-load current at full voltage under exact operating conditions, showed that the switches were still in good condition. The switches have also proved satisfactory as regards flash-over voltage when in the open position. Five 500 kVA and seven 300 kVA, 11 kV distribution transformers have been automatically operated on a large urban system for some years, and on an average there have been 240 tap changes per transformer per day.

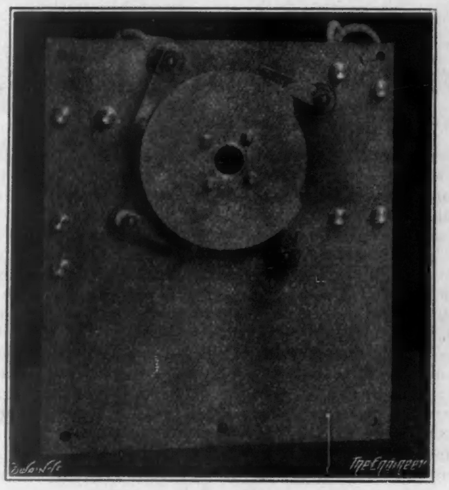


Fig. 16—Switch Operating Cam

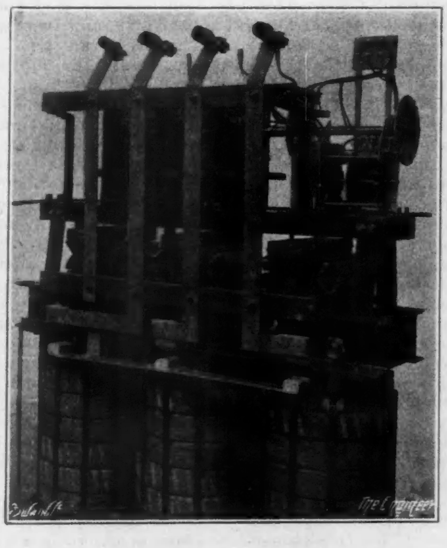

Fig. 17—Three-Phase Ferranti Mercury Switch Regulator

The electrical connections, as shown in Fig. 14, conform with recognised practice, a centre-tapped reactor being used to limit the circulating current between tappings, and a maximum of eight switches per phase is used to give fifteen running positions or fourteen steps. Current and voltage ratings of the mercury switches are the only factors that limit the range of application of the apparatus, the limitation in any particular case usually being due to one or the other, and seldom to both. With the differential auto connection shown in Fig. 15, the scope of the gear can be greatly increased by permitting one of these values to be reduced where necessary at the expense of the other. In this way the range of application can be more than doubled. In all cases the tap-changing gear is connected to the high-tension side of the transformer, and the tappings to it are brought out from the middle of the winding, as shown in Fig. 14, an arrangement that offers the advantage that, as the high-tension winding is usually the outermost winding in a distribution transformer, tappings brought up ducts from the inside winding are avoided. Another advantage which arises from the practice of bringing the tappings from the high-tension or primary windings is that it reduces the losses cost.

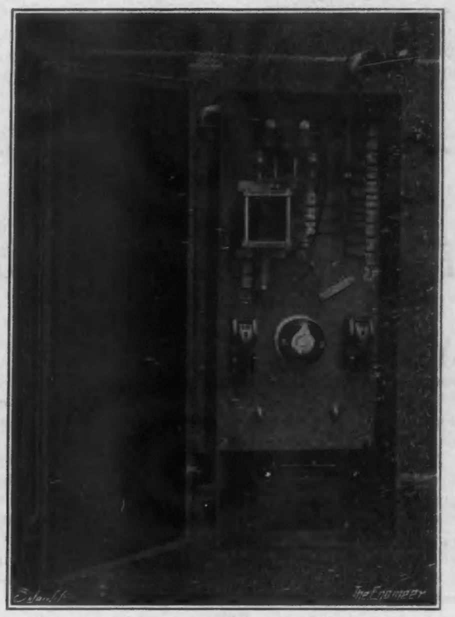

Fig. 18—Automatic Control Panel

At times of no load either the input voltage is high or a low output voltage is required, and the tap-changing gear automatically brings the full winding of the transformer into use, thus reducing the flux density, with consequent reduction in loss and magnetising current. With a voltage range of ± 10 per cent. the actual no-load losses of the transformer is said to be reduced by 30 per cent., and the no-load current by 50 per cent.

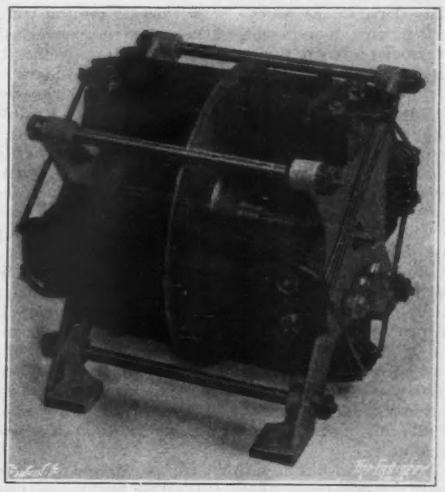

Fig. 19—Induction Disc Motor

The mercury switches are mounted on rocker arms on vertical bakelite plates around a central operating shaft. Four switches are carried by each plate, and two plates forming one phase are assembled back to back on either side of a bakelite cam mounted as shown in Fig. 16. A three-phase assembly is shown in Fig. 17, from which it will be gathered that the spacing between the phases allows easy access

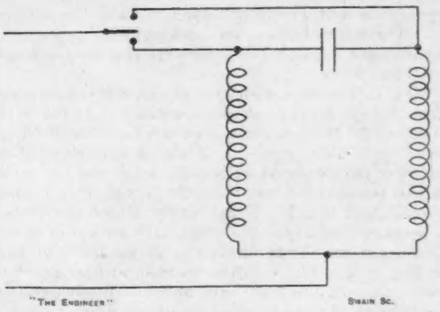

Fig. 20—Motor Connections

to the switches. The main shaft is spring-operated through single steps by an induction disc-type motor, and as all the switches of any one phase are operated by a common cam, departure from the correct sequence of operations is impossible. As shown in Fig. 17, all the apparatus is mounted on top of the transformer. It is immersed in oil, a scheme which is made practicable by the fact that no part of the mechanism requires inspection or maintenance. On-load tap-changing gear of this type can be added to standard transformers with no increase in floor space, and only approximately 20in. increase in height.

Automatic Control Panel and Motor.

As shown in Fig. 18, the automatic control panel associated with this gear is simple, which is due very largely to the fact that the power required to operate mercury switches is small. The induction disc-type motor used for operating the gear is shown in Fig. 19. Its driving elements consist of two iron-cored coils mounted on either side of a copper disc forming the rotor. As shown in Fig. 20 a condenser is connected in series with one of the coils and the flux interactions in the rotor provide the driving torque. A single two-way switch controls starting and stopping and also the direction of rotation. Owing to the low speed of the motor and its simple construction it is eminently suitable for operation under oil, and as the starting current does not exceed the running current the motor is never overloaded.

(To be continued.)

Research on Steels for High Temperatures.

At the Connaught Rooms, London, on Wednesday, November 22nd, 1933, a conference was held in connection with research on steels for use at high temperatures. Sir J. A. Ewing, K.C.B., was in the chair and there were present representatives from most of the industries concerned with this problem.

The Chairman, in opening the conference, said :—I would only remind you that we are here for the purpose of encouraging a particular industrial research, and you will expect me perhaps, as Chairman, to say a few words about its purpose and history, about the nature of the problem, and how it is being attacked, about the finance proposals, and about the reasons for helping this research. Our hosts to-day, as you know, are the British Electrical and Allied Industries Research Association, with whom are co-operating the National Federation of Iron and Steel Manufacturers. During the war the Department of Scientific and Industrial Research was created and has remained to us as one of the few beneficent legacies of the war, one of the things which we are now realising is an exceedingly valuable co-operator in the recovery of something like industrial prosperity.

The particular research which we are going to speak about to-day is a good example of the way in which that Department works. It works essentially by inviting the co-operation of the industries concerned, it associates with them and gives them specifically scientific advice, and it also supplies a considerable part at least of the necessary funds for the purpose of research. At the same time, it very properly, I think, acts upon the policy of virtually saying to industry, here is a problem which will benefit you if it is carried out and solved. It is therefore evident that you should shoulder part of the cost and we will contribute part out of Government funds, and together we will attack this problem, carrying the baby—as Mr. Wedmore once said in one of his letters to me—for a limited number of years until it is able to walk by itself. That is essentially the policy of the Department of Scientific and Industrial Research. Some of its problems are of a very broad scientific kind, and the one which we are most concerned with to-day of a general kind is the one which is in charge of a Committee over which Sir Robert Dixon presides, namely, the investigation of the high temperature properties of all sorts of metals and, I think, other bodies as well as metals.

We know also that within a comparatively few years back the constructive steels used in bridge building, architecture, &c., have been immensely improved, the range of strength and elasticity has been very much widened by various firms of steel makers by adding small quantities of other constituents. Our problem to-day, however, is a different one. We are concerned with the quality of steel to resist high temperatures generally in combination with fairly high stresses. I am afraid that is really a more difficult problem than perhaps any of the others with which steel makers have hitherto been faced, but it is a problem well worth attacking because the solution would be a very big advance indeed in our engineering possibilities, especially as regards the conversion of heat into work.

May I, therefore, shortly state how it comes about that this question of steel enters into that particular problem ? Most of you here are familiar with the fact that in the conversion of heat into work what the engineer is concerned with essentially is what is now called the heat drop, *i.e.*, the drop from a high temperature to a low temperature, which the turbine or whatever other machine he is using is going to take advantage of. At the bottom end we are now down to bed-rock. The condensers that are supplied for steam engines now have such an exceedingly excellent vacuum that there is really nothing more to get at that end, but there is no such limitation at the other end. If only we could take heat from the coal, or whatever is the fuel, into the working substance which expands in the engine, at a high temperature, then we could get much more out of it than if we took it in at a comparatively low temperature. Sir Charles Parsons demonstrated by his experiment on the steamship "King George V." the practicability of running ships' turbines with a temperature such as had never been applied, certainly in ships before, and it is a point about which every central station engineer is now concerned, namely, to get the great turbines which he uses for generating electricity to take in highly superheated steam at a high pressure, and the central station engineer finds himself limited at present by the difficulty of getting steel that will do the job. This is the clearest case of the limitation of materials checking progress in engineering. The object of this research is to see whether we cannot stretch that higher limit of temperature so that it will be a little higher than it is now. I do not think we can expect to stretch it very much and probably at the best we can only get it up by 100 deg. or 200 deg.; but it is eminently worth doing even that. I understand that Mr. Guy, who has had great experience in the design of turbines, will tell us that even 100 deg. may mean more than 5 per cent. improvement in the reduction of the coal bill for a given power.

We have this fact, then, that turbine builders are restricted, and, indeed, the users of superheated steam for any purpose are restricted, by the difficulty of finding steel capable of standing high pressure and high temperature together, and Admiral Dixon's Committee, which deals with the whole question of high temperatures in metals, has handed over a portion of their work to a Joint Committee which was created under the auspices of the Department of Scientific and Industrial Research to deal separately with this problem. This Committee of Admiral Dixon's may be called the parent Committee, whilst the Joint Committee has been fostered by the two bodies I have already named as our hosts to-day. The position is that they have gone a considerable way towards a solution of the problem. They have been carrying out systematic researches at the National Physical Laboratory and the technique of these researches is very difficult. Moreover, the apparatus for it which has been established at the National Physical Laboratory is costly, and there is a very great advantage—an obvious advantage—in co-operation for this purpose, because the job is too big a one really for any small maker to take on by himself. There has been a definite arrangement come to with the Department of Scientific and Industrial Research. The matter has been going on for several years, and in the early stages there was a contribution of £ for £ by the Department of Scientific and Industrial Research, the Department finding half and the other half of the money being found by the two bodies, which I have already named. They would like now, however, to widen the basis ; they want to make this research more active than it has been, they want to bring into it other users and other manufacturers who are concerned. Not only that, but the Department of Scientific and Industrial Research, which is very conscious of the importance of the problem, has volunteered to give a larger sum provided it is met by a larger contribution on the industrial side. Here is an extract from a letter from Sir Frank Smith, the Secretary to the Department of Scientific and Industrial Research, to Mr. Wedmore, the Director and Secretary of the Research Association. It says :

> "The Department attaches much importance to the organisation and support, by industry, of your Committee's investigations—which are intended to assist both steel makers and makers of plant to keep pace with the modern tendency continually to raise the working pressures and temperatures in steam plant for power production, and, therefore to maintain and, it is hoped, to increase the share which British industry already has in supplying the world's demand for this kind of plant and machinery. As you know, the Department is carrying out at the National Physical Laboratory, at the sole cost of public funds, a programme of research into the root problems of the behaviour of materials at high temperatures.
>
> "The work which your Committee has been undertaking is regarded by the Department as a necessary complement to its own work. It is work which is likely to lead to results of direct practical value to industry. Not only should the planning of the work be informed by industrial experience such as your Committee can provide, but we should look forward to the day when this work should be regarded as deserving a high priority in the field of industrial research represented by the Research Association movement.
>
> "As a demonstration to industry of the practical usefulness of your Committee's work, intended to enlist the co-operation of interested firms, the Department has, as you know, been meeting approximately half the cost for a number of years. We shall be gravely disappointed if this demonstration should not achieve its object. In the present financial circumstances we are bound to concentrate efforts on those fields of research which seem most likely, for whatever reasons, to bring immediate assistance to industry. You will realise that active development in the work of your Committee will, in turn, establish more firmly the claim of our own more long-range work to continued support from public funds.
>
> "With this long preamble I can turn to the offer we have made. I am pleased to confirm that the Department will be prepared, in accordance with the terms of its official letter to you of August 30th, 1932, to continue to contribute until September 30th, 1935, half the cost of the work up to £1500 per annum. Beyond that date it is our hope that industry, and especially those sections of it which are represented by the Electrical Research Association and the Iron and Steel Research Council, will be convinced that the work ought to be absorbed into their own research programme. In that event I feel sure that the Advisory Council will not hesitate to press on with the Department's more basic investigations designed to throw up problems for more *ad hoc* attack."

That means, in effect, that the Department is offering £1500 a year, provided always that industry supplies at least another £1500 a year, and I do not think that such a sum as £3000 a year or more, if it can be obtained, is at all excessive as an investment. Perhaps investment is not quite the word, because after all, what you are working for is a sort of sporting chance of a very marked betterment in the principles for the conversion of fuel into power. I should not like to put it much higher than that because we cannot be quite confident that even these protracted investigations and the long and laborious job that they involve will ultimately result in very much heightening the temperature at which steel can be used. They have already, however, as Mr. Guy assures me, resulted in a definite improved heightening of that temperature, and there is good hope for believing that with further tests on various substances as ingredients of the steel, there will be a definite improvement. At all events, it is eminently worth trying, and even if it fails you will at least have this satisfaction, that you have investigated the matter and have given industry a definite guidance and lead, and have removed—and this, I think, is a point worth mentioning—what is at present the real limits of danger in the design of some of this plant, and, further, you will have the satisfaction of knowing that this is being done as a British concern. In such a matter we do not want to allow our country to lag behind other countries which are taking up the same problem and working at it. It is clearly, as a mere piece of business foresight, desirable that British engineers who have taken the leading place in the development of steam power, should go on taking that leading place until this problem is definitely solved.

I think I ought not to take up any more of your time, and I will now call upon the other speakers and will first ask Mr. Guy to make a statement.

Mr. H. L. Guy (Chief Engineer, Mechanical Department, Metropolitan-Vickers Electrical Company, Ltd.) :—I do not want you to think that the electrical industry, for whom I speak, at first took kindly to the idea of co-operative research. In fact, we are in the position of penitents, and if salvation can be obtained by confession I am free to confess that at least the larger firms felt that they possessed technical knowledge, experience, and skill which had cost them a great deal in money and research, and they felt that by encouraging a mutual enterprise such as co-operative research they would of necessity be placing at the disposal of less provident competitors part of the stock-in-trade which they had acquired by foresight and at considerable cost. Ultimately they came to realise that the competitors who mattered most to-day in business possessed unsuspected resources of a like kind which were not insignificant compared with their own. Further, we found that there were certain urgent questions, the exploration of which, if pursued by an isolated member of an industry, would be limited and slow. We also found it was an immense advantage to deal with fundamental researches in a co-operative manner and to deal ourselves with other researches which were of more immediate and special interest to ourselves.

The importance to us of this particular research which we are discussing to-day, however, arises from the general trend in steam practice, which during the last twenty years has been marked by a steady and persistent increase in the temperature of steam employed, an increase which has averaged 100 deg. Fah. in each five years. At each definite stage in this progress we have had to encounter special problems with regard to the materials employed. For instance, in the period from twenty years ago to ten years ago we saw the almost complete elimination of non-ferrous alloys and the substitution of ferrous material. During the last ten years, however, we have been introduced to an entirely new conception of the properties of materials which demand new methods of treatment which have not yet been fully discovered. I should imagine that the problem of creep, which has been introduced with the development of high temperatures, is as important a change in steam practice as is relativity to astronomy. In the range of temperatures with which we are concerned to-day in our ordinary work, and which this research has been concerned with for the past ten years, we can no longer speak of iron and steel as having definite strength apart from the temperature to which they are subject and the temperature fall they are called upon to endure under a particular stress and so perform their duly appointed functions. We have had to develop entirely new methods of attack on our structural problems based on using materials in a plastic condition instead of an elastic condition. Moreover, apart from this question of creep, the allied problems of the embrittlement of material at elevated temperatures and the effect of oxidation and corrosion on stressed materials at high temperatures, are of equal moment. In fact, the very structural stability of the material itself may be in question. Already certain exploratory work has been done in this direction and it must be exhausted in the next stage of this particular research.

It may be urged that the ultimate user being the ultimate gainer should foot the bill. It may be argued that it is only the operator of a power station who gains by the application of the knowledge obtained from such researches, but I suggest that that is not true or, at any rate, not wholly true, because if it were, how could you explain the fact that amongst the most constant supporters of research have been the constructors of the machinery for power stations ? They are not the users of the machinery and they are not the ultimate beneficiary. The principle to seek in this matter is the one the Chairman has referred to, namely, that we shall retain the leading manufacturing position in the world's markets.

With regard to this particular research on the properties of materials at elevated temperatures, I am able to say to-day that the electrical industry will continue its support at the increased rate of contribution it made last year, when other subscriptions waned, without imposing the limitation of four years, which has been suggested.

Mr. A. J. Grant (managing director, Thos. Firth and John Brown, Ltd.) :—I speak on this subject as a steel maker and on behalf of other steel makers who are engaged particularly in the manufacture of this class of alloy steel. I should like not only to refer to high-pressure steam problems which have been previously mentioned, but also to the developments that have taken place in oil cracking and the chemical industry which calls for even higher temperatures and pressures than hitherto have been used in steam practice. It is quite evident that if this country is really to get its nose in front in developments of this nature, not only for steam work, but for chemical and oil plants, it is very necessary that systematic research should be started on this subject. I think I can safely say that the makers of alloy steels have loyally supported this work up to the present, in spite of the straightened circumstances that we have all been in lately in the steel trade, and we intend to continue to do so. Therefore I should like to appeal, not only to the makers of alloy steels, but to the makers of ordinary steel, because unless material of this nature can be satisfactorily made in this country such works as the great works at Billingham and such enterprises of the Imperial Chemical Industries as the hydrogenation of coal would be impossible. I think it is almost pitiable that the comparatively small sum which the Chairman mentioned should not be readily available from the steel industry, from the electrical industry, from marine engineers and shipbuilders, with whom pressures are increasing and superheat is increasing almost every day. It is almost pitiable that there should be any real necessity for this meeting at all to secure money for this research. The foreigners, as we know, are spending a great deal of money on questions such as this, and many private firms themselves are spending large sums of money on research. The private firms, however, which have money confine their experts to problems which are related to particular work which, to themselves, is likely to result in orders, and there is no doubt that fundamental research should be carried on at an institution such as the National Physical Laboratory. Therefore, on behalf of the alloy steel makers, I feel I am quite safe in promising what Mr. Guy has promised on behalf of the electrical industry : that we shall continue to support the work of this Committee, and I hope the basis of subscription will be very much broadened to include others who are not now supporting it. I am sure it would be in their own interests to do so.

Admiral Sir Robert Dixon, K.C.B. (director, Babcock and Wilcox, Ltd.) : My remarks to-day are made chiefly to the manufacturers and designers of steam engines and boilers, whether for use on shore or afloat. I think it will not be contested that steam in this coal-raising country will continue to supply the major power that is required in our various plants. It is obvious that the insistent call for further economy must lead inevitably to the use of higher steam pressures and temperatures, as the chairman has already said, and to modifications in design which will lead to plant less exacting in its demands both as regards space and upkeep. All these things will call for more from the engineering materials, and whether it be ashore or afloat, a ton of material will in future be expected to go farther than in the past. I am not, I think, overstating the case in saying that the continuity of progress in the economy of steam plant will only be possible if materials well fitted to retain the desired strength and form to resist wear and waste when working at higher temperatures are made available for our use.

Whilst this research in the past has, in the main, been financed, so far as industry's share of the expenditure is concerned, by those interested in prime movers for land installations, it is obvious that the knowledge which will be acquired is of equal significance and importance to the manufacturers of boilers and to all those associated with propelling machinery for marine work.

It is, I think, merely indifference, inspired by the problem being for the moment viewed as a somewhat distant one, which has resulted in this and collateral researches in the past having evolved so little interest in marine circles. Personally, however, I think the problem is imminent. I am fully persuaded that steam plant will become of increasing significance in marine work in the near future, but I am convinced that if it is once again to assume the predominant position to which its merits entitle it, it will be by taking the utmost advantage of the unique properties of steam as a heat carrier, and using it in much higher ranges of pressure and temperatures.

Thus the problem is, for marine designers, of much more than academic interest, and it behoves us to render appropriate support, and assist to get results so that the British shipping industry can walk on the ground floor as and when the advanced materials become available ; and continue, as in the past, to lead the world in economical and suitable marine designs.

I should like to say that this matter concerns the shipbuilders no less than the marine engineers and shipping people, because there is an inevitable tendency for a ship herself to be built in places where advanced machinery designs are developed and made or are readily available.

The connections, for example, between the growth of the shipbuilding industries in the Scandinavian countries and the oil engine development work is, in my view, very much to the point. It would be more than a pity, if, in advances pertaining to steam which promise so much, and which this country has pioneered from the beginning, that we as a country should lose our honourable position by reason of a lack of appreciation of the significance of this problem.

In conclusion, and speaking now for the particular boiler manufacturers with which I am associated, I can promise that they will gladly continue their support for the four years which has been suggested.

A general discussion then followed, and in conclusion the Chairman called upon Dr. Rosenhain and Sir William Larke.

Dr. W. Rosenhain, in supporting the appeal for more generous financial assistance for this research, emphasised the point made by the Chairman as to its lengthy and costly nature. The less money that was available, the more lengthy the investigations, and in another sense they were more costly, because they had to be carried out over a greater number of years. The demand for immediate or early results was a very natural one, and was a matter with which he and every member of the Committee sympathised. At the same time, there was a little misconception on the part of those who thought they had to wait three years for results. The three years period had been mentioned merely as a measure of the time for which support was asked, and it did not in the least follow that there would be no results until three years had elapsed. Whatever results were obtained were published, or at any rate made available to those concerned, as soon as they were sufficiently well established to be worth attention on a practical scale. On the other hand, it must be borne in mind that in many of these cases there was a very important time factor. The whole problem of creep, for example, was one of time, and unfortunately there had yet to be found a thoroughly satisfactory method of determining by a quick test the creep behaviour of any material. Some very ingenious methods of testing had been devised, and they gave an approximate idea of that phenomenon of intercrystalline fracture to which the Chairman had referred, but although these tests were very ingenious, the results were seldom all that were desired, and therefore it was necessary to depend mainly upon tests which extended over many weeks, and in some cases many months, and this meant time as well as money.

With regard to the actual position of the research, continued Dr. Rosenhain, he could not say much without becoming highly technical. Although the research had been started in an entirely systematic manner, it was found that it involved the exploration of an almost illimitable field if proceeded with on those lines, and, therefore, they had been led away from that strictly scientific scheme into something approximating to the trial and error methods of industry, by investigating the properties of certain types of steel which had been suggested as the results of practical experience as being promising. The molybdenum steels were a case in point, and some very interesting results had been obtained. The future course of the Committee, if it were adequately supported, was to carry out systematic work, and at the same time give attention to those particular varieties of steel which experience suggested were worth investigating.

Sir William Larke said that as one who had been the channel of appeal in connection with this research, he urged on all present the necessity for exercising their influence in the interests they represented, whether institutions or companies, in order to get this research supported to the fullest possible extent, and to bring it to the notice of those who had the deciding voice in authorising contributions. It could not be said too strongly that unless we improved our general technical and technological position we should certainly go on having losses until we had no work to do, and, speaking as one who had tried to exercise some little influence in encouraging industrial research in various capacities, Sir William said that if we did not encourage industrial research we should deserve all we got.

The Chairman, in bringing the Conference to a close, repeated that the Government offered £1500 a year for a period of three years, provided no less was contributed by industry. The British Electrical and Allied Industries Research Association had offered £750 for that preiod, and there was a contribution from the National Federation of Iron and Steel Manufacturers for £350 or £400 a year for the same period. Thus, there was still something required in order that the Government contribution might be secured. It was not the desire, in the least, to limit the amount provided by industry to £1500, and it was obvious that it would be to the very great advantage of the research if other bodies would give sums which would secure a larger total income in order that the research might proceed more quickly. It was not sufficient merely that the research should be done ; it should be done, and must be done, as quickly as by competing countries, or more quickly if this country was to hold its own.

On page 554 we print a statement by the B.E.A.I.R.A. on the present position of the research.

SIXTY YEARS AGO.

IN our issue of December 5th, 1873, we reprinted a short note taken from the *Nautical Magazine*, in which a comparison was made between the number of lives lost on British railways, by street accidents in London, and as a result of shipwrecks round our coasts. The conclusion reached was that the sea, with all its dangers from hurricanes, fires, and collisions, was much safer than railways or even streets. The comparison was undoubtedly rendered quite valueless because it dealt only with the absolute numbers of lives lost, and did not take into account the great difference in the numbers of lives exposed to the risk of loss. It was in actual fact worse than valueless ; it was thoroughly ill-timed. Hardly had the paragraph been written before an event at sea occurred, to pass, as it were, stern commentary upon it. The news was received that the "Ville du Havre" had been in collision with the "Loch Earn," and that both vessels had sunk with the loss of 222 lives. The disaster was in several respects, apart from the heavy list of casualties, a notable one. The "Loch Earn" was a sailing ship of 1200 tons. The "Ville du Havre" was a C.G.T. liner of over 8000 tons displacement. By some misunderstanding concerning the rule of the road at sea, the sailing ship proceeding at a moderate speed in a light breeze, struck the liner amidships and tore an enormous rent in her hull below the water line in the neighbourhood of the engine-room. Within a quarter of an hour the liner sank. Numbers of the passengers and crew succeeded in getting away from her in the boats, but apparently they clung too closely to the doomed ship. As she sank she listed and her masts and spars crashed down on the boats, killing many of those in them. The "Loch Earn" saved 87 lives, but these survivors found that they had been rescued from a ship that had gone to the bottom by one which was on the point of doing likewise. An addition to the tragedy was, however, avoided, for just before the "Loch Earn" sank, a passenger liner passed and took off those on board. The "Ville du Havre" was built for the Compagnie Générale Transatlantique at the Thames Ironworks in 1865. Originally she was known as the "Napoleon III.," and was driven by paddle wheels. With three similar, but slightly smaller, ships, she was placed in the hands of Andrew Leslie and Co., of Hebburn, and by that firm was lengthened by 50ft., and re-equipped for screw propulsion. As reconstructed, she had a length of 413ft., and was the largest passenger steamer afloat at that time, with the exception of the "Great Eastern." The disaster occurred very soon after she had been placed in commission again. Writing immediately after the event, we expressed our great concern at the fact that a liner of this size could be so severely damaged by a sailing ship in fair weather as to sink within a short time. We expressed the tentative opinion that she must have been structurally weak, and that her water-tight subdivision must have been defective. Subsequently, Messrs. Leslie supplied us with drawings of the hull which we published. These, together with evidence which we collected from survivors and by examining the work being done on the three sister ships, convinced us that the disaster was not caused by structural weakness, but rather by the failure of the liner's crew to close the bulkhead doors immediately after the collision had occurred. The British court of inquiry at a later date also found the liner to blame. The French court, on the other hand, blamed the "Loch Earn." The conflict between the findings caused much comment.

Beardmore High-Speed Oil Engines.

ON the occasion of a recent visit to the Dalmuir Works of William Beardmore and Co., Ltd., we inspected the large and well-equipped oil engine department of the firm, which, it will be recalled, was, earlier in the year, moved from Parkhead to Dalmuir. At this works there is now centralised all the engineering work of the firm other than that which is directly connected with the Parkhead Forge. In the Dalmuir establishment, the oil engine department has been organised as a separate entity, laid out for quantity production. We saw in course of construction nearly one hundred high-speed oil engines for road and rail transport, electric generating, and industrial and marine purposes, many of them under erection or test.

A NEW HIGH-SPEED OIL ENGINE.

As we have on several previous occasions dealt fully with the Beardmore oil engine for road and rail transport, we have on this occasion chosen for description and illustration a new six-cylinder marine engine, which has been constructed for working at moderate speeds with maximum reliability. The design of this special unit embodies improvements which have been suggested by the firm's long practical experience in the operation of high-speed oil engines.

The engine which is illustrated herewith has recently been despatched to a foreign Navy, and is one of two units to be installed in a fast-running, shallow-draught vessel for lake service. It has a normal rating of 225 B.H.P. when running at 1200 r.p.m. The cylinder bore is 6½in., the stroke 9in., and the two-hour overload rating is 250 B.H.P. During the recent official tests, which included a six-hour full-load trial, and a two-hour overload trial, both engines were shown to be capable of developing 260 B.H.P. each at 1300 r.p.m., an output which would be considerably increased by the adoption of supercharging.

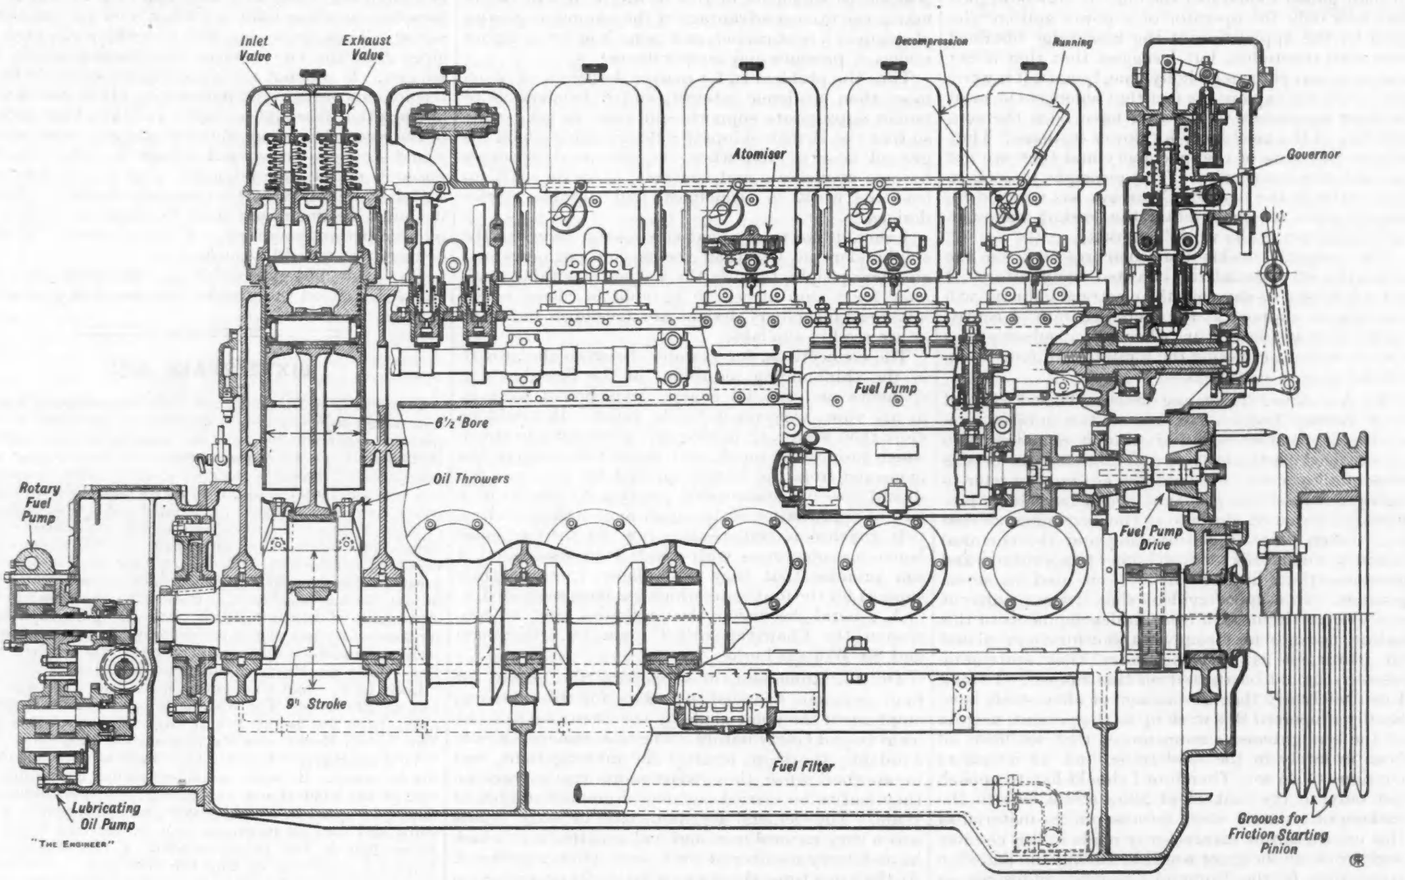

FIG. 1—LONGITUDINAL SECTION OF BEARDMORE 225 B.H.P. SIX-CYLINDER MARINE OIL ENGINE

The total weight of the engine complete with self-contained auxiliaries and clutch and reverse gear is 2 tons 7 cwt., or a little over 23 lb. per B.H.P.

We attended demonstration trials of one of the units on the test bed and were invited to test for ourselves the manœuvring qualities of the engine. We found the unit to be very quiet over all ranges of speed, and on moving the control lever there was a quick response in both the ahead and astern directions. The engine idled quietly at about 400 r.p.m., and progressive increases of speed up to 1200 and 1300 r.p.m. rapidly followed the advance of the running control lever. There was a marked absence of torsional vibration over the speed range chosen. The guaranteed fuel and lubricating oil consumptions obtained under test-bed conditions with a tolerance of 2½ per cent., were :—

	Grammes per H.P. hour.
At full load	200
At three-quarter load	195
At half-load	209
With a lubricating oil consumption of ..	5

The consumption figures at the official tests fell within the guaranteed figures without resorting to the allowed tolerance, but no attempt, it may be noted, was made to attain minimum consumption.

An interesting auxiliary fitting is a Dumbflow silencer, to the design of which we shall refer later. In this apparatus the cooling water of the engine is usefully employed to cool the exhaust and reduce its velocity, and alike, whether running light or under full-load condition, the exhaust was remarkably quiet.

FEATURES OF DESIGN.

Although we are describing a marine unit, the essential ideas of the design have been directed towards the production of a standard unit which, by suitable modification in auxiliary attachments, can be adapted equally well for generator driving or rail transport, and we noted, going through the works, several similar engines for these and other industrial services.

CRANK CASE CYLINDER AND RUNNING PARTS.

The sectional drawings reproduced herewith show clearly the main details of construction. The main framing and upper part of the crank case are a single casting of nickel chrome iron, which is of simple multi-cellular construction, the compartments carrying the cylinder liners and forming the cooling water jackets for each cylinder. The cam shaft is housed in a chamber formed at the top of the main framing, which is enclosed by a detachable cover. The lower part of the main casting carries the crank shaft bearings, there being one bearing between each pair of cylinders with additional bearings at each end. All crank shaft journal bearings are secured by underslung steel caps. The crank case is furnished with large doors giving good access and facilitating the removal of the connecting-rod bearings.

The engine underbed is a nickel iron casting, to which the crank case is bolted. It is arranged with extensions at the fly-wheel end to take the electric generator, clutch and reverse gear, or other driven units, and can be adapted to suit any particular requirements. The underbed also carries the main bearings and the layshaft for the drive to the auxiliary units which are arranged at the end of the engine remote from the fly-wheel, as shown in Fig. 1. A well is formed in the underbed to collect the lubricating oil passed through the engine system.

The crank shaft is carried in white metalled bronze bearings, adjustment being provided for by a thick shim plate. The spigoted coupling at the fly-wheel end is forged solid with the shaft, and the end of the crank shaft remote from the fly-wheel is arranged to take a vibration damper. A spur gear which drives the gear train for operating the cam shaft and engine auxiliaries, is arranged between the last main bearing and the fly-wheel bearing.

The cylinder head casting is generally made of aluminium alloy, with the valve seats of alloy steel, cast in position, but when salt sea water cooling is employed nickel cast iron is used. As our drawings show, the cylinder head contains one inlet and one exhaust valve arranged along the centre line of the engine, the fuel atomiser being at the side and placed horizontally. When the engine is designed for compressed air starting, air admission valves are provided.

The cylinder liners are interchangeable and are made from steel forgings, machined all over, the bore being ground and the outside surface treated to prevent corrosion. The top end is flanged and held between the cylinder head and the top of the crank case, copper joint rings being interposed on both sides of the flange to form the gas and water joints. The lower water joint is made by two rubber joint rings, which allow the liner to expand in a downward direction, as required.

The pistons are of the trunk type and are die cast in a special heat-treated aluminium alloy. They carry four gas rings and two scraper rings, one above and one below the gudgeon pin. The hollow gudgeon pin is free to float in the piston bosses and the small end bush. It is made from high-tensile case-hardening steel and is fitted with soft metal caps.

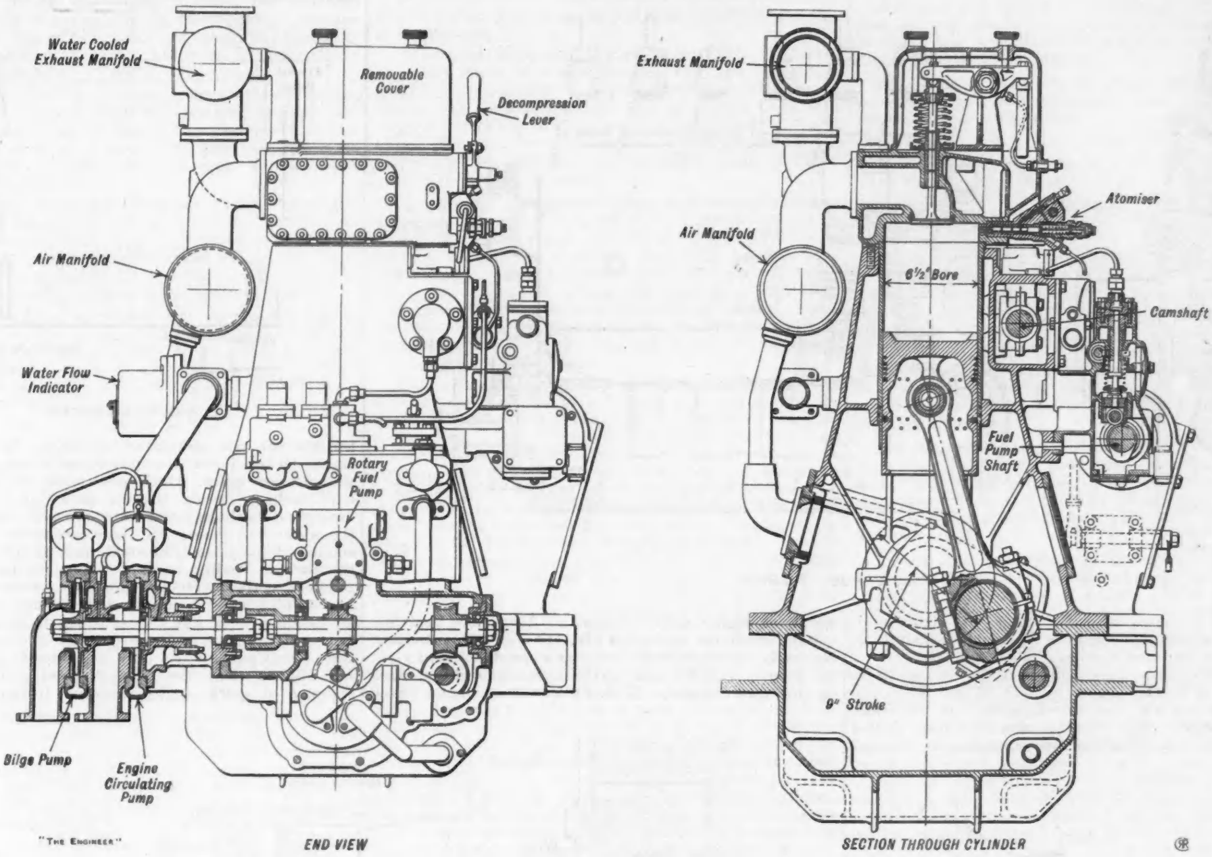
A connecting-rod of "H" section made in high-tensile steel is used and the top end bush is phosphor-bronze, while the bottom or big end bushes are made of a special bronze white metal lined, a thick adjustable shim plate being provided for adjustment. Two high-tensile steel bolts are employed to secure the connecting-rod cap to the rod. All the rods and pistons are adjusted to the same weight to secure balance of the reciprocating parts.

VALVES AND VALVE OPERATING GEAR.

The valve rocker levers are carried on a bracket which is secured to the top of the cylinder head, the whole of the valve gear being enclosed by an easily detachable cover made in light aluminium alloy. Both the inlet and exhaust valves work in renewable guides pressed into the cylinder head, and the exhaust valve is made of special heat-resisting steel. All valves are provided with two concentric springs, the upper spring cages being held in place by split cone washers fitting into recesses formed on the valve spindles. On the tops of the valve spindles there are steel caps, which contain hardened steel balls flattened locally where they make contact with the tappets on the valve rocker levers. The balls roll in their steel cages so that wear on the tappets is eliminated.

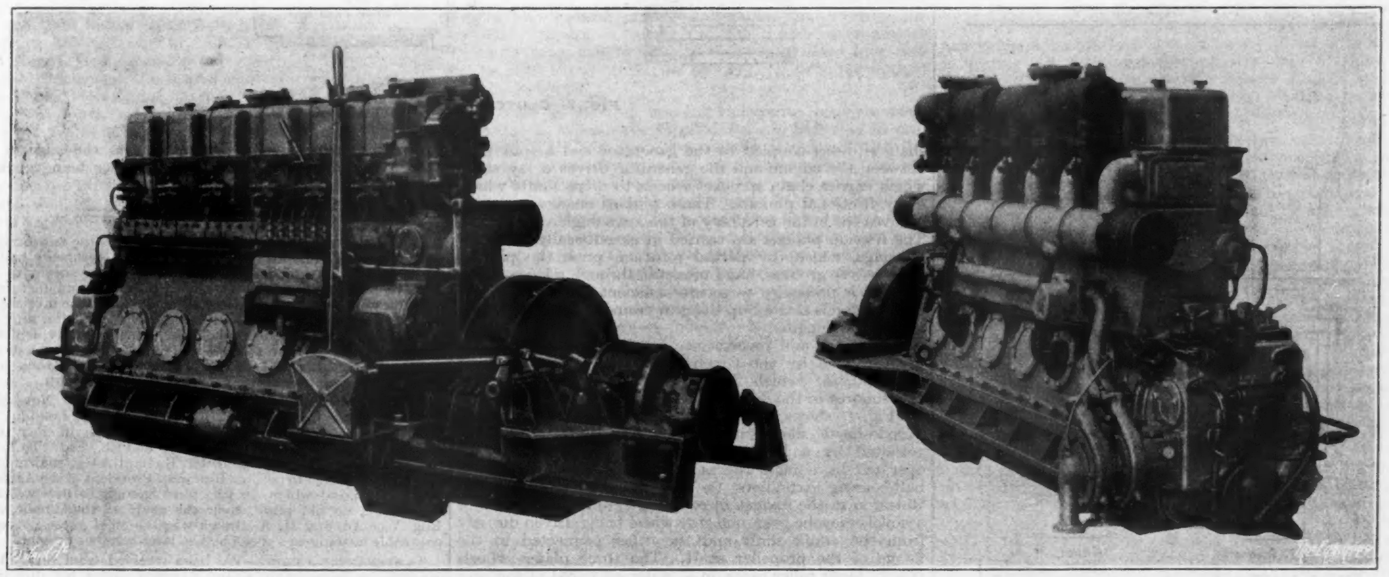
The tappets are of the roller type and are fitted with hardened steel rollers and pins, a floating bush being interposed between roller and pin. They work in cast iron guides which are spigoted and secured to the crank case with studs. The tappet guide top is positioned in the casing formed in the cylinder head and is made oil-tight by a rubber joint ring. The valve motion is taken from the tappets to the valve rockers through hollow steel push rods with hardened steel ball and cup ends which are pressure lubricated. All the valve rocker levers are finished with bronze bearings which are lubricated from the main engine system, while channels cut in the rocker levers permit oil to flow to the valve stems and push rod ends, the surplus oil being returned to the cam shaft chamber through passages provided in the tappet guides. The cam shaft can be dismantled after removing the cam shaft chamber cover, and the top caps of the bearings. In carrying out this operation the cam shaft driving gears remain undisturbed, as they are mounted on a short shaft fixed at one end by a ball bearing. The cam shaft engages this gear shaft by means of driving keys fitting into slots cut in the faces of the couplings formed on the two shafts ; the two halves of the coupling are secured together by a bolt passing through the centre of the gear shaft. The removal of the cam shaft chamber inspection cover also exposes all the tappets and rollers. The cam shaft and all the cams are drilled for lubrication, the oil being fed into the hollow centre of the shaft.

The gear train between the crank and cam shafts is housed between two walls forming a chamber in the main casing of the engine at the fly-wheel end. The gear wheels are of the single helical and straight spur types. They are mounted on fixed spindles with long bronze-bushed bearings lubricated under pressure. The first gear engaging with the driving pinion on the crank shaft is arranged at the side of the shaft so that any variation in the vertical position of the crank shaft during adjustment of the main bearings does not affect the correct meshing of the gears. The gear train, in addition to driving the fuel pump, governor, and cam shaft at the fly-wheel end of the engine, also drives a lay shaft carried in the underbed. This lay shaft transmits the drive to the cylinder jacket water circulating pumps, lubricating oil and fuel oil booster pump, which are placed at the opposite end of the engine. These are clearly shown and illustrated in Figs. 2 and 5. A power take-off is also provided for such purposes as driving a bilge pump, air compressor, &c., when required. As all the auxiliaries and other drives are taken from the fly-wheel end, they are not materially subjected to the effects of minor torsional oscillations. As shown in Fig. 1, the fuel pump is mounted on the same side of the engine as the atomisers and cam shaft. It is compact in form and is easily removable for inspection. The pump drive is taken from the gear train through an Oldham coupling, adjustment being provided at the coupling to facilitate timing the pump. The pump is of the standard Beardmore constant-stroke variable-delivery type with one pump plunger for each cylinder, the plungers being driven by a cam shaft running at half engine speed.



END VIEW SECTION THROUGH CYLINDER

FIGS. 2 AND 3—END VIEW AND SECTION OF ENGINE



FIGS. 4 AND 5—VIEWS OF ENGINE FROM FLYWHEEL AND FUEL PUMP ENDS

The measurement of fuel and the period of injection into the cylinders is controlled by partial rotation of the plunger, this movement being effected by the governor. The hardened plunger has no recesses or sharp edges on its periphery and is balanced so far as side loading is concerned. The top edge is well chamfered and communication with the controlling edges of the liner is obtained by a central axial hole and two cross holes placed diametrically opposite one another.

The pump liner is made in two parts, the lower portion having a helical upper edge which controls the amount of fuel injected, while the upper portion is recessed and fitted over the lower part, the upper end of the recess controlling the beginning of the injection period.

Screw-adjusted tappets are used to bring the plunger into correct relation with the control edges on the liner, and the plungers can be individually set to bring the cross holes of the plunger into correct radial relation with the helix on the liner.

For certain classes of service fixed timing may be employed, but when the engine has to operate over a wide range of speeds and loads it is preferable to vary the time of the injection. This variable timing of the pump is obtained by altering the angular relation of the fuel pump cam shaft to the engine crank shaft, and is done automatically by linking up the motion of the governor speed setting mechanism to the operating mechanism of the timing gear, so that the period of fuel injection is determined for each speed setting.

The atomiser is of the closed differential spring-loaded needle type. It consists of a stamped steel body with a removable hardened steel guide and hardened steel needle, an adjustable spring holding the needle upon a coned seat in the steel nozzle, which is of the multi-hole pattern. The lifting pressure of the valve can be adjusted.

A governor of simple centrifugal type, mounted vertically above the driving end of the cam shaft and worked from it by spiral bevel gears, is used. It operates the fuel pump throttle through the medium of an hydraulic relay, and is designed to control the engine speed variation within close limits. For rail traction work with electric transmission in which the engine is required to operate over a wide range of speeds the governor is fitted with a speed control mechanism designed to fix the engine revolutions at predetermined figures; thus speeds of 400, 800, 1000, and 1200 r.p.m. or any other combination may be provided for a particular duty. The mechanism, which is operated electro-hydraulically, also furnishes a simple means for coupling together two or more engine controls for operating from one driving station.

For rail traction work the solenoids which operate the valves of the governor controlling the flow of oil under pressure are in circuit with the master controller. The engine speed is, therefore, automatically varied according to the requirements of the driver. The solenoids are so arranged that in the event of failure in the electrical circuits, the engine automatically comes down to its idling speed. The oil supplied for operating under pressure the governor relay and speed control mechanism is obtained from the main engine lubricating oil system. For marine work, as in the engine we are describing, or in applications in which any speed between idling and full speed must be obtained, the solenoid valves are dispensed with, and a hand throttle lever is used, which operates the speed control mechanism through a pilot valve. Thus, for any hand throttle setting, the appropriate speed is obtained, and the load which must be carried on the engine at this speed is automatically determined by the governor. An emergency governor is also fitted in order to prevent the over-speeding of the engine in the event of the main governor failing. It is mounted on the free end of the fuel pump cam shaft, and consists of a rotating weight whose centrifugal force acts upon a spring. When the speed rises above a predetermined figure, the weight moves a trigger which is connected by suitable mechanism to the trip gear of the fuel pump. When the trigger is released the fuel supply is cut off, and the suction side of the pump at once drained.

LUBRICATING SYSTEM AND SERVICE PUMPS.

Two lubricating oil pumps are provided, their casings being cast together so as to form one unit. They are mounted on the vibration damper casing, which has also incorporated in it two Auto-Klean filters. The pumps are of the gear type, and are designated the "scavenge" and "pressure" pumps respectively. The scavenge pump suction is connected to the engine bed-plate sump, and delivers oil through the filter to the oil storage tank through the oil cooler or a radiator when provided.

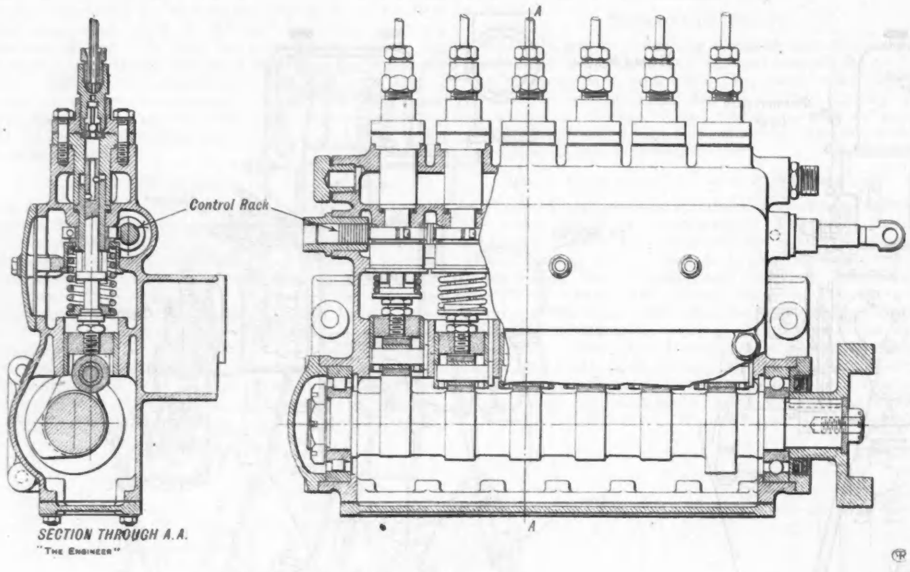


FIG. 6—FUEL PUMP

The pressure pump draws oil from the storage tank and delivers it to the engine by way of the filter, the external main rail, and the drilled passages in the crank case to the engine main bearings, and thence by drilled passages in the crank shaft to the connecting-rod big-end bearings. Suitable tappings are taken off the main system to lubricate the gear train spindles, the gears, and valve-operating mechanism, and to supply the oil relays in the governor. The booster fuel and drain pumps are of the rotary gear type built into one unit, and also mounted on the vibration damper casing. The booster fuel pump draws fuel oil from the fuel tank and delivers it under pressure to the main fuel pump. The drain pump suction is coupled to the surplus fuel collector tank and discharges the surplus fuel back to the tank. The water pump is of the centrifugal type with a cast aluminium alloy casing and a bronze impeller. The bilge pump in the case of marine applications is of the same pattern, and it is mounted alongside the circulating water pump and is driven from the same spindle. This is clearly indicated in Fig. 2.

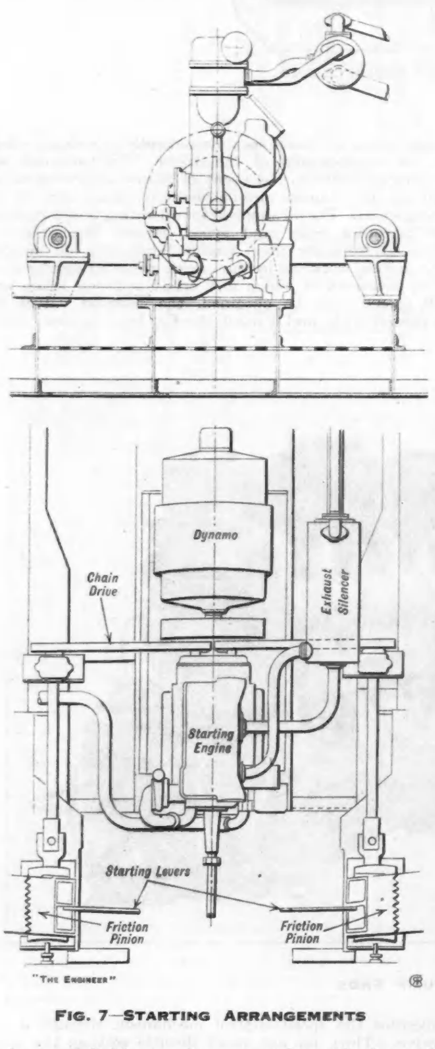

FIG. 7—STARTING ARRANGEMENTS

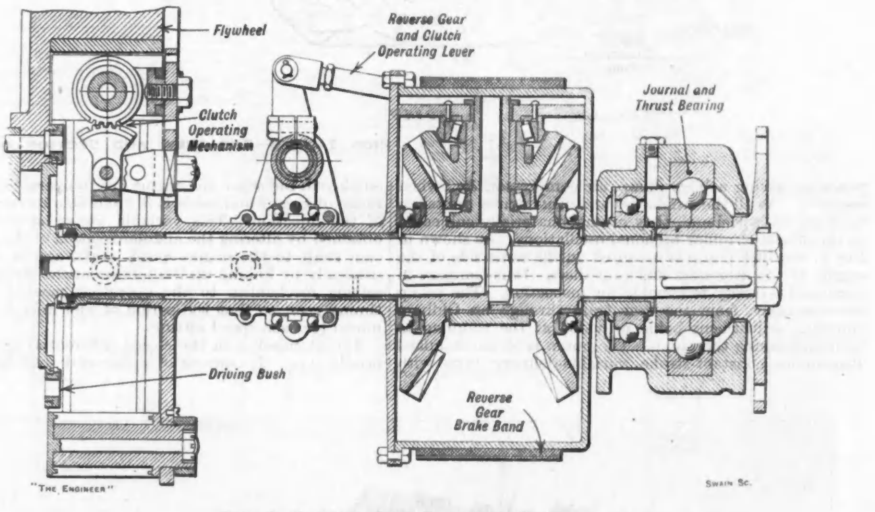
STARTING AND REVERSING ARRANGEMENTS.

As shown in Fig. 7, each main engine as installed in the ship is started up by means of a small Beardmore high-speed oil engine with cylinders of 3½in. bore and 5in. stroke, which also drives a 4 kW, 110-volt D.C. generator. Normally, the small engine runs at a speed of 1200 r.p.m., but when it is used to start up the main engine, it is speeded up to approximately 2200 r.p.m. The engine crank shaft is direct-coupled to the generator and a spur gear between the engine and the generator drives a lay shaft which carries chain sprocket wheels to drive shafts which carry frictional pinions. These pinions engage with vee grooves cut in the periphery of the main engine fly-wheels. The friction pinions are carried in excentrically mounted housings, which, by partial rotation, press the pinions into the vee grooves, hand pressure, through a lever, being all that is necessary to secure sufficient adhesion. After each engine is started up the gear train is disengaged from the starting engine.



Flywheel
Reverse Gear and Clutch Operating Lever
Journal and Thrust Bearing
Clutch Operating Mechanism
Driving Bush
Reverse Gear Brake Band
"THE ENGINEER"
SWAIN SC.

FIG. 8—CLUTCH AND REVERSE GEAR

The clutch and reverse gear is of the open type, and was supplied by the Green Engine Company, Ltd., of Twickenham, which firm collaborated with Messrs. Beardmores in the design of the control lever mechanism. As Fig. 8 shows, the clutch consists of two expanding Ferodo-lined shoes, inside the fly-wheel. They are actuated by a left and right-handed screw, which is operated by a rack, the motion being transmitted by a ball-bearing trunnion to the cross-operating shaft. Rotation in the reverse direction is obtained by means of a bevel epicyclic gear, one gear wheel being driven directly from the crank shaft and the other connected to the flange of the propeller shaft. The three planet wheels run on taper roller races on a spider anchored in the gear drum, and in order to obtain reverse rotation this gear drum is held by means of an external Ferodo-lined brake band. A duplex double-thrust race is arranged on the final drive flange. Both this race and the journal race are housed in a sea-water-resisting aluminium thrust bracket, which has a seating on the engine bearers. The operating shafts of the brake band and clutch are connected by tubular levers to a control box which carries the hand control lever. These are so arranged that one lever operates both the forward and reverse direction of the craft. The interlocking device and the controls are so devised that the engine power is limited in order to suit propeller characteristics to 135 H.P. for astern navigation purposes. The reverse gear cannot be engaged until the engine revolutions have dropped to the idling speed.

SILENCING ARRANGEMENTS.

The Dumbflow patented silencers, already referred to, were supplied by the Universal Electrical Manufacturing Company, of Peckham, and there are two—one silencer per engine. They were made under a guarantee to render the exhausts inaudible at a distance of 150 m., while both the size and weight of the units and the back-pressure were required to be reduced to the minimum.

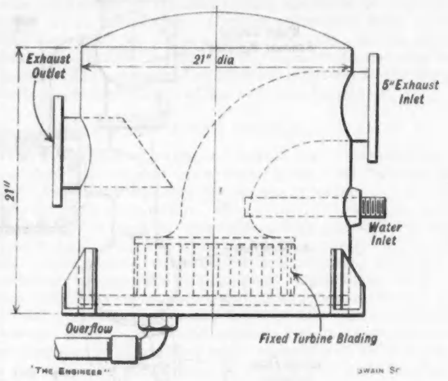


FIG. 9—SILENCER

As Fig. 9 shows, each silencer is 21in. high and of the same diameter, the 5in. exhaust from the engine being led into one side and out of the other. Water from the engine jackets is led into the silencer where it mixes with the exhaust gases, which are caused to pass through fixed turbine blading, thereby imparting a rapid rotary movement to the gas and water mixture, thus converting the water into foam. By these means an instantaneous cooling of the gases is effected, and, as the gases leaving the turbine blading enter a vortex, or point of lowest pressure in the revolving foam, back-pressure is avoided. The surplus water is continuously drained away through an overflow pipe, any excess being discharged with the gases. By means of the arrangement described, it has been found possible not only to eliminate exhaust noise, but also to clean the exhaust gases and prevent the emission of sparks under abnormal working conditions. A vacuum-breaking port is provided in the silencer in order to prevent any possibility of water being sucked back into the engine.

A RAPID BUILDING FEAT.—The contract for the new Spillers flour mill at Avonmouth stipulated that the steel work had to be in position in eight weeks. This included the survey of the site, the preparation of the working details, the manufacture of the steel and rolling of the materials at the mills, the fabrication in the shops, the delivery and unloading at the site, and the actual erection of the steel members. This was duly achieved by Dorman, Long, who took 4½ weeks from the receipt of the order to effect the first delivery at the site, and then only 3½ weeks to erect the entire 1500-ton steel framework.

W. H. ALLEN, SONS AND CO., LTD.—Last Saturday, November 25th, there was held at the Criterion Restaurant, London, the twenty-first annual dinner of the Association of Past and Present Students of W. H. Allen, Sons and Co., Ltd. To mark the "coming of age" occasion, Mr. Richard Allen, chairman of the firm, was asked to become Honorary President of the Association, a proposal which he was kind enough to accept. Mr. K. Rowell, an old pupil, took the chair at the dinner, and Eng. Vice-Admiral H. A. Brown was the chief guest. A very enjoyable evening was spent by the large number present.

TEMPERATURE CHART.—We have received from Sir Robert Hadfield a temperature chart prepared under his direction. It is a new edition, with considerable improvements and additions, of a previous chart prepared some years ago. Temperatures are given on the Centigrade scale, and the range extends from Absolute Zero to the temperature of the Electric Arc (3700 deg. Cent.). On the right-hand side of a conventional thermometer stem, the melting and boiling points of various materials are tabulated, these being separated into two columns for more ready reference. The first column shows the boiling points of the elements, and the melting points of refractories and other materials used principally in metallurgy. The second column is confined to the melting points of the elements. On the left-hand side are indicated the temperatures corresponding to the temper colours of steel, together with various natural and industrial temperatures. The purpose of the chart is to present to those concerned in convenient form various temperature data of general interest.

Railway and Road Matters.

Locomotive "No. 6201" of the L.M.S. Railway, sister to the "Princess Royal," has been named "Princess Elizabeth."

The "Royal Scot" train of the L.M.S., which has been touring the United States and Canada, and has covered there some 13,000 miles, is due back in England by way of the "Beaverdale" early in December.

As related in our Seven-Day Journal, the Southern Railway is about to extend its electrification services by a further 23 route miles, *i.e.*, from Orpington to Sevenoaks, and from Bickley and Chislehurst to Sevenoaks *viâ* Swanley Junction.

It is reported that the Campbeltown and Machrihanish Light Railway, which is nearly 6¼ miles long, is of 2ft. 3in. gauge, and runs across the Mull of Kintyre, is to be wound up. It was opened on August 17th, 1906, and has three locomotives, six carriages, and two vans. Its failure is due to road competition.

The London Passenger Transport Board seeks for powers in the Bill that will come before Parliament next year to substitute trolleybuses on 90 miles of the routes now served by tramways. All these are in the outer London area, presumably because the trams there are operated by overhead equipment and not by conduit.

Workmen engaged on alterations to Wembley L.M.S. station have brought to light a ninety-six years old cast iron plate bearing the initials of the London and Birmingham Railway, London's first main line railway. The plate, which was affixed to the bridge carrying Wembley High-road over the railway, dates from the opening of the line from Euston to Boxmoor in 1837.

The Ministry of Transport railway statistics for the month of August show that, compared with the corresponding month of 1932, the number of passenger journeys increased by 5·7 per cent., and the receipts therefrom 13·9 per cent. The tonnage of freight rose by 9·9 per cent., and the freight traffic receipts by 7·0 per cent. The freight train mileage was 3·5 per cent. higher, the average train load rose from 115½ tons to 121 tons, and the net ton-miles per engine-hour from 436½ to 457¾. The last represents the speed in transit and this is very gratifying.

Speaking before the Great Western Railway Debating Society on October 19th, Mr. A. S. Quartermaine, that company's assistant chief engineer, said that steel sleepers had been laid on 156 miles of the Great Western. The lecturer also spoke of various methods of packing the sleepers, and said that while experiments had been made with pneumatic "tampers," the method had not been found better or more economical than the traditional method of "beater" packing. Fly-packing, a process in which the track was lifted and a suitable quantity of fine ballast sprinkled over the sleeper bed, was, however, being used extensively.

According to the Railway Returns there were, on December 31st, 1932, 668,868 wagons owned by British railways, a decrease during the year of 13,891. There were also 13,605 brake vans. The total tonnage capacity of the wagons was 7,475,433 tons, a decrease of 119,080 tons. The average capacity per wagon was 11·41 tons, as compared with 11·35 tons. The number of wagons of a capacity of 20 tons and over—exclusive of special vehicles—was 28,689, as against 28,915 at the end of 1931; 26,700 of these in 1932 were allocated specially to mineral traffic, as compared with 26,867 in 1931. In view of the agitation in certain sections of the public Press for 20-ton wagons these decreases show that the wisdom of the railways is against that idea.

In our Annual Article of January 13th last, "British Railways in 1932," we gave a description of the deviation of the Cheadle single-line branch of the London, Midland and Scottish Railway. The railway runs from Cresswell, on the main line of the former North Staffordshire Company, to the terminus at Cheadle, and is 3¾ miles long, including Cheadle Tunnel, half a mile in length. Owing to coal settlement the tunnel needs considerable repairs, but it has been found to be a less expensive matter to divert the line at a point north of the intermediate station of Tean by building a new railway 2¼ miles in length, all in the open. This has now been completed, and the line was opened on Sunday, November 26th. The work has involved the construction of two bridges over public roads, and one over the river Tean, and some 145,000 cubic yards of earthwork had to be dealt with.

On the evening of Saturday, August 26th, a passenger train on the Sirhowy branch of the London, Midland and Scottish Railway was detained at Tredegar Lower Junction home signal because a Great Western train was passing on to the same line at the next box in advance. An engine and van should therefore have been detained at the next box in the rear, Nine Mile Point No. 2, but for some reason which the man could not explain, the signalman there lowered his starting signal and allowed the van to proceed. Recognising his error later, he telephoned to Tredegar Lower Junction signalman, and that man put the home signal to "clear" in order to get the passenger train out of the way. Whilst the signal was "off," the engine and van approached and the collision followed. The accident was inquired into by Colonel Trench, who puts the blame for the mishap on the signalman at Nine Mile Point No. 2.

The circular railway which runs around Paris will probably be closed to passenger traffic shortly, except on the electrified section between Auteuil and Courcelles, where it joins the main line from the Gare Saint-Lazare. Prior to 1900 this railway offered the only means of mechanical transport in Paris, apart from a few lines of compressed air and steam tramcars, and its prosperity declined rapidly with the coming of the motor omnibus. Attempts were made recently to galvanise it into life with the use of oil-electric locomotives, but the experiment failed, and the company proposes to suppress the passenger service from the beginning of next year. Omnibuses run so frequently at all points around Paris that competition for traffic is no longer possible. The railway does useful service between the goods termini of the main lines which are situated near it, and it will no doubt continue to be employed for goods traffic.

Notes and Memoranda.

An experimental tea factory is to be put up at Serdang, Federated Malay States, where a considerable plantation has been laid out.

The Krivoi Rog iron deposits of Russia are estimated to contain 700 million tons of ore, of which 211 million tons are considered to be commercially workable. The ore is said to be of the red hematite type with a content of 66 per cent. of Fe. There are also deposits, said to contain 10 billion tons of 40–45 per cent. quartzite iron ore, in the district.

On account of the hook of the hoisting tackle on a crane, especially those of a steel foundry that are exposed to great heat, developing cracks and resulting in a disastrous failure, the Demag Company has evolved a hook that might be described as being made of "ply steel." Should any of the plies develop a defect, it will not reduce the strength of the hook beyond the safety limit, and that piece can be easily replaced.

The recently opened power plant at Vernon, California, which has a capacity of 35,000 H.P., is driven entirely by oil engines. The present installation of 37,500-kVA consists of five 7500-kVA units. Each unit consists of a 7000 B.H.P., eight-cylinder, double-acting, two-cycle, 167 r.p.m. oil engine, direct connected to a 7500-kVA, 0·8 power factor, 7200-volt, 50-cycle generator. These Hamilton-M.A.N. engines, built by the Hooven, Owens, Rentschler Company, are the largest now in stationary service in the United States.

Some very striking figures regarding actual tooling costs applicable to heavy-duty milling in cast iron of medium hardness were quoted by Mr. R. E. W. Harrison during the course of a paper read recently before the American Society of Mechanical Engineers. It was stated that a milling cutter designated type A will remove 6000 cubic inches per grind and can be re-ground seventy times. A set of blades for such a cutter costs the user approximately £4 5s., so that more than 400 cubic inches of metal can be removed for 1d. invested in high-speed steel. With a cutter designated type B, which has an actual metal removal life of 1,620,000 cubic inches per set of plates costing the user £5 15s., a volume of nearly 1200 cubic inches of cast iron can be removed for an expenditure of 1d. on high-speed steel.

An article in *Chemical and Metallurgical Engineering* points out that blast-furnace slag, owing to its content of lime, alumina, and silica, is a cheap and suitable material for the manufacture of glass. Experiments have shown that molten slag straight from the blast-furnace may be directly converted into glass, thus effecting a fuel saving. The glass produced can be readily cast or rolled, but it is difficult to make it transparent, owing to the presence of 1 per cent. iron oxide, although dark-coloured glass can be readily produced. A semi-transparent glass with a high refractive index, and which is opaque at a distance of a few yards, can also be made, according to work at the Alabama Polytechnic Institute. These glasses have a low coefficient of expansion and a great strength, are heat-resisting and unattacked by boiling water, hot caustic soda and boiling hydrochloric acid.

Sound travels freely through chemically dried air, particularly at low temperatures. The introduction of small quantities of moisture promptly damps off the sound, especially tones of high pitch. Peculiarly, this phenomenon does not occur when pure nitrogen is substituted for the air, in spite of the fact that air is nearly 80 per cent. nitrogen. A shift to pure oxygen in the experiment reveals this latter gas as the guilty party. But oxygen alone is rather ineffective. Water vapour must also be present to affect the sound waves. Experimental records agree with the theory that the water molecules catalyse, or inspire oxygen molecules to pick up sound waves, convert them into heat or other motion, and thus destroy the sound. The extent to which all this occurs varies greatly with the frequency or pitch of the sound. Thus arises one more good argument for the new art of air conditioning in public buildings.

A new method of case-hardening has recently been introduced, which, says *Shipbuilding and Shipping Record*, overcomes the disadvantages usually associated with the process as ordinarily practised, viz., the necessity of having boxes of sufficient size to contain the piece, and the time taken. In this new process the parts to be hardened are dipped directly into a bath consisting of a special case-hardening mixture in the form of a thin paste, and they are then put into the furnace without any packing. In addition, the time required in the furnace is considerably less than when the ordinary box-hardening process is required, the pieces, on being taken out of the furnace, being plunged into an oil bath, where they are cooled off. Thus, with ordinary mild steels the carburising time to obtain a depth of 1 mm. is from sixty to eighty minutes after the work has attained the furnace temperature, which should be in the region of 930 deg. to 940 deg. Cent. It is also claimed that the short time required for treatment offers the further advantage that the possibilities of distortion are greatly reduced.

The recently opened bridge over the Teesta River is the largest concrete arch in India, and was built on a steel arch centering. As it was difficult to calculate the deflection of the centering under the load of the concrete, some method of getting over this difficulty had to be devised. This was done, says *Indian Engineering*, by means of sand bags—the steel arch was loaded with exactly the same weight as the weight of the concrete in the arch rib, and as the concrete was placed in the forms the sand was thrown into the river, thus keeping the load uniform and the shape of the arch constant. This, we understand, is the first time that this method has been used in India. Similarly, when removing the steel supporting arch, sand bags were again placed on the steel arch until the downward movement was sufficient to enable the packing between the concrete and steel arches to be removed; this allowed the concrete arch to take up its own position without shock. This is a most important consideration in concrete construction of this nature, as the concrete at this stage has only developed a certain proportion of its ultimate strength.

Miscellanea.

Ten new food canning factories have been established in Great Britain this year, making a total of eighty-two canneries throughout the country.

Statistics show that England has exported 15,000 motor cycles and tricars valued at £500,000 during this year. During the first ten months of this year we exported 158,000 "push" cycles.

A resolution confirming the amalgamation of the Ross Institute with the London School of Hygiene and Tropical Medicine was passed unanimously at a meeting of the members of the Ross Institute.

The coal deposits of the Faröe Islands are to be developed by Danish interests to the extent of 100,000 tons a year as a preliminary. It is estimated that there are 100 million tons of coal available.

A regulating dam is to be built at Fort Peck, on the head waters of the Missouri River. It is to be of earth, will have a height of 230ft., and will impound 17,000,000 acre-feet of water. The estimated cost is about 75,000,000 dollars.

Eighty per cent. of the contracts for the equipment of the new sugar-beet factories in the Irish Free State, amounting to more than £1,000,000, have been given to Germany, and the remaining 20 per cent. to Czecho-Slovakia.

The Board of Trade gives notice that it has referred to the Standing Committee an application for an Order in Council to require the marking with an indication of origin of chain or pulley blocks, whether imported complete or in parts.

The two new liners for the New Zealand trade of the Blue Star Line, which have been ordered from Harland and Wolff, of Belfast, are to be finished by the end of next year. They will be 515ft. long by 70ft. beam, and have a speed of about 16 knots. The propelling machinery will be oil engines.

The capacity of the ferro-manganese works at Sestafoni, in South Georgia, the erection of which started in 1930, is reported in the *Iron and Coal Trades Review* to be 150,000 tons per annum in eighteen furnaces. Up to the present three electric furnaces have been in operation. A new railway between Schoropanj and Sestafoni is used for conveying the manganiferous ores to the furnaces, while coal is furnished by the Tkwibuljski coalfield, some 24 miles from the works.

Ten motor omnibuses have lately been despatched from Birmingham to Hyderabad for use by the Nizam's Railways, which will now have the largest and most up-to-date motor fleet in India. Twenty-seven motor omnibuses were ordered from England three years ago when the need for co-ordinating the road and rail services became apparent, and it was decided that the State, in addition to running railways, should run public road vehicles.

A plan to shift the course of the Charles River for about three-fourths of a mile in Cambridge and Brighton, Mass., has been prepared by the Metropolitan District Planning Commission at Boston, Mass. With an estimated outlay of about 700,000 dollars, it is intended to swing the channel of the river eastward toward Soldiers Field and the Harvard Stadium; to build a bridge across the river at Gerry's Landing, near the Cambridge Hospital; construct two traffic circles at the ends of the bridge, and build two overpasses for foot traffic.

Manchukuo is reported to be making plans for the erection of an oil refinery at Hulutao. This plant will have a daily capacity of 4000 barrels of gasoline, and may commence operations with imported crude oil, probably from Russia. In the neighbourhood of Hailar there are crude oil seepages, and geologists are there to prospect and prepare for drilling this summer. If oil is brought in paying quantities, another refinery may be built at Hailar. There are, says the *Far Eastern Review*, said to be two most important and promising oil fields in Manchukuo. One is near Chiufutan in Jehol Province.

The change in the basis of manufacture which brought into existence the production engineer actually took place, said Mr. Still in an address to the Industrial Administration Students' Union, at Thames House on November 23rd, during the nineteenth century, when the engineering industry had become so complicated that some measure of specialisation became necessary. Interchangeability brought standardised tools and gauges; the tool-room brought the tool designer, who became a specialist; and the necessity for studying the operations and processes for which the tools were intended brought the planning department; while further development brought the progress man and the inspector. It was at this stage that the production department became necessary to preserve a proper co-relation between the stages of manufacture, and the production engineer to control both the manufacturing processes from the very beginning, and the supply of raw material.

The construction work under the national "grid" electricity scheme has been completed so far as the South Wales section is concerned, and thus forms the concluding stage of the national scheme, which links up every big station in England, Scotland, and Wales. According to Mr. A. P. Healy, the engineer-in-charge of the "grid" in South Wales for Messrs. Kennedy and Donkin, consulting engineers to the Central Electricity Board, the construction of the South Wales section has taken two and a half years, and involved the connecting up of Gloucester, Portishead, Newport, Cardiff, Upper Boat, the new station at Tir John North, Swansea, and Llanelly. Six hundred pylons have been erected and 300 miles of aluminium wire have been used. During the construction of the transmission lines many different types of obstacle had to be overcome, including the crossing of six rivers, at each of which clearance had to be provided for shipping. These crossings are from high towers, which now form landmarks the whole way from Gloucester to Swansea. The towers at Newport and Newnham are approximately 300ft. high.

STEEL RESEARCH.

Last week a small conference on Steel Research took place in London. It was called by B.E.A.I.R.A. and the National Federation of Iron and Steel Manufacturers, and its purpose was to ensure that enough money would be forthcoming to continue the research into steels for use with high pressures and at high temperatures which has been proceeding for several years. The minimum sum required is ridiculously small when the importance of the investigation and the size of the industries affected are borne in mind. It amounts to no more than £1500 a year for three or four years. If the industry will provide that little sum, then the D.S.I.R. will find a like amount. It is to be presumed that £3000 is held to be sufficient for the prosecution of the research, but the rapidity with which results can be attained depends upon the funds available, and it is hoped that much more than the minimum which is necessary to secure the full D.S.I.R. grant will be subscribed. The impression left by the conference is, we are glad to say, that the contributions will exceed the minimum, but some of the promises made were rather vague, and at this stage it is impossible even to guess at the total income which may be put at the disposal of the research workers.

We have said that the sum which the steel industry is invited to subscribe is ridiculously small. It is so small that one wonders why it should have been necessary to call a conference to get it. We would have expected that a mere written request to steel makers and users would have met with an immediate response which would have more than satisfied the necessities. Badly as our steel firms have been hit by the depression, we find it hard to believe that even the weakest of them cannot find a ten or twenty-pound note for an investment so rich in promise. Their avowal of inability to spare so small a sum is so incredible that we may be forgiven for suspecting that excuses of poverty, when they are made, really cover a disinclination to support the research. That disinclination may spring from several sources. It may be held that the research is not worth while at all, or that it is being carried out in the wrong way, or that individual research is better than co-operative research, or that the firm is able to provide the desired material already even if its competitors are not, or, finally, it may spring from unscientific-mindedness. It may be of some interest to consider these objections in a little detail, but as far as most of them are concerned, the answers will be found in the report of the conference which we print on another page. There our readers may find good arguments for the contention that the research is really worth while. Sir Alfred Ewing, who was in the chair, showed with that simplicity of which he is a master, that the further progress of the steam engine depends almost entirely on the discovery of a material which will stand much higher pressures and temperatures than our present steels will tolerate without creeping. That is not a matter which concerns individual firms of steam plant manufacturers alone. The prestige of the country —an invaluable trading asset—is also affected. If some other nation makes the discovery first it will assuredly gain an advantage, both because of its ability to provide the necessary material and by the enhancement of its reputation. We can imagine that those who believe that the days of steam are numbered will retort that the internal combustion engine is not affected by the research, and that, therefore, it is hardly worthy supporting. But, apart from the fact that further progress of the oil engine, and particularly of the internal combustion turbine, may hang upon the availability of the desired material, the fact remains that for many years to come steam will hold its position and the production of steam plant will be a national asset. Furthermore, as Mr. Grant pointed out, it is not the steam engineer alone who is asking for a new steel, but chemical engineers need it for plant employed in the cracking of oils and the hydrogenation of coals, both subjects of immediate interest to the maker and user of internal combustion engines. Thus, from whichever side we look at it, the discovery of the new steel is nationally desirable. With the objectors who criticise the nature of the research and its slowness in providing results, we leave Dr. Rosenhain to deal. He showed that it involved the performance of a vast number of experiments and tests, and whilst he admitted that a more systematic method might be desirable if time and expense were of no moment, he saw no alternative to the trial-and-error method, which was being pursued. The question of individual as opposed to co-operative research is one much more difficult to handle. Firms point to their own successes, and claim that what they have done by themselves in the past is evidence of what they can continue to do. It is impossible not to sympathise with them; not to feel that a firm which has the foresight and the energy to carry on expensive investigations should get some direct benefit from them. Many companies take this attitude; they do not believe in Research Associations, and will not contribute to their costs. Several of our leading steel makers are already at work on this very question; they seem to be on the verge of success; admirable steels, which very nearly satisfy the requirements, are already available; it needs but a little more to reach the very goal at which the associated research is aimed. On what grounds can these people be expected to provide funds for work which may anticipate the results which seem almost within their grasp? That is an extremely difficult question to answer. The only plea is one of national interest, and through the national interest the interest of every individual. It must be accepted as a possibility that the co-operative research will reach the desired end before any one of the individual researches, or it may lay a scientific foundation on which further advances may be prosecuted. If it does either of these things the whole steel industry of the kingdom will reap advantage and every individual firm, even though it be not a maker of the new material, will benefit. That is an important point. It is not the steel makers alone who will reap advantage from the wished-for discovery, but every firm whose business is affected by the use of the new material. The boilermaker, the steam pipe maker, the turbine builder, even the electrical plant manufacturer, all stand to gain by an improvement of steel products. This fact is well recognised in some quarters, but perhaps some companies which have not considered it may, hitherto, have been inclined to withhold contributions on the ground that the matter was not one in which they were interested. May we hope that, for the good of the industrial welfare of the country as a whole, they will review their attitude. Finally, there is the indifference of those firms which are not scientifically-minded. Even at this day such firms are not rare. They look with suspicion on scientific activities, and refuse to give them financial support. Their attitude in many instances is quite comprehensible. Their industry is not conducted amongst scientific people, and the people to whom they sell are satisfied with the product offered to them. They dread rather than welcome the disturbance which science in its progress may cause, and are only to be moved out of their complacency by the successful competition of more enterprising manufacturers. It is difficult to bring effective argument to bear on firms which are entrenched behind present success. But their position is being gradually weakened by the development of Research Associations and the activities of the D.S.I.R. If nothing else could be claimed for that Department, we should have to allow that it is performing the function of an educational body and that it is causing, slowly but surely, more scientific-mindedness amongst manufacturers.

We have endeavoured to present a few arguments in support of those much more ably advanced by the speakers at the conference. We trust they may do a little towards loosening the purse strings of those who have so far not contributed to the research. Industry is on the mend. The pendulum is swinging in the right direction at last. A small impulse now will propel it on its course. If tomorrow or the next day the wanted steel could be found, who knows what impetus it might give to the revival, who knows how much it might do to increase Great Britain's competence to defy the competition of other nations? The sum required is so small by comparison with the potentialities which lie in a successful discovery that the steel industry itself and collateral industries should find it four or five times over. May we suggest to those who are not actually opposed to co-operative research, but who from no more than indifference, have not contributed towards the expenses that, even if it is nothing more, it is a sporting venture on which a few pounds may be wisely risked.

Water Survey.

Among the reports considered at the Leicester meeting of the British Association in September last was that of a committee appointed after the York meeting of the Association in 1932 to inquire into the position of inland water survey in the British Isles, and the possible organisation and control of such a survey by central authority. The report of this committee, whose chairman was Vice-Admiral Sir H. P. Douglas, formerly the Hydrographer of the Navy, has just been issued as a British Association reprint (No. 31). It contains, in addition to a general description of the present state of water conservancy and survey in Great Britain, a series of appendices prepared by individual members of the committee and others on existing survey organisations and records in this country and abroad. It is recalled that demands and suggestions for a survey of the water resources of the country, and for a central water authority, have been made on many occasions in the past, and the report draws a clear distinction between an organisation for carrying out a water survey and a central authority or National Water Board for the administration and control of water resources. It is with the former only that the committee was directly concerned. A Joint Select Committee of both Houses of Parliament in 1910 expressed the opinion that there was need for a comprehensive survey of the water supply of the country, and, in 1921, the Board of Trade Committee on Water Power Resources, in its final report, recommended the establishment of a Water Commission for certain purposes. The passing of the Reservoirs (Safety Provisions) Act, 1930, and the establishment of Catchment Boards under the Land Drainage Act, 1930, again drew attention to the subject as a matter of immediate urgency, particularly as regards the gauging of streams and rivers to provide reliable data on which to base estimates of flood flows. One result of these enactments was the appointment by the Institution of Civil Engineers of a Committee on Floods to whose first report we recently called attention in these pages. The discussion at the York meeting of the British Association last year indicated a unanimous opinion in favour of the setting up of a national organisation for water survey.

The scope of a water survey necessary to meet the requirements of civil engineers and others interested in water conservancy should, in the opinion of the Committee, include observations and measurements and the preparation of continuous records in standard form in connection with rainfall, surface storage and flow, and underground storage and flow—in conjunction, in each case, with the physical and geological characteristics of the area. The British Rainfall Organisation, now a Department of the Air Ministry, which has grown from small beginnings as a private enterprise, provides the indispensable information as to rainfall on which engineers have hitherto had largely to depend for water-flow data. There is, however, no such existing department or central organisation to deal with direct hydrological measurements of the amount of water derived from rainfall. The Committee has considered the various systems of providing hydrometric data adopted in other countries, seeking some useful guidance from their example and experience, rather than a model which can be copied, since the conditions differ very materially. For instance, irrigation, which is vital in some countries, is of minor importance in Great Britain; hydro-electric development is a necessity in many countries, floods on British rivers do not compare in magnitude with those experienced in some parts of America; and in many cases there remain in other countries very extensive water resources as yet undeveloped. In Great Britain, on the other hand, the predominant interest is the ever-increasing need of public water supply for domestic and trade purposes. Second only to this in importance are the problems of drainage, floods, motive power, navigation, and fishing. Though the organisations of other countries, therefore, do not afford a model, their experience, particularly that of the United States, points to two important principles: (*a*) That the investigational activities of a survey should be segregated from those related to construction and administration, and (*b*) that continuous and reliable records can be collected only by the State. If these principles be accepted, as in the opinion of the Committee they should, it necessarily follows that the organisation of a water survey must be a national undertaking. The ideal to be aimed at for Great Britain, therefore, is a Government department (or section of a department) working as a central hydrometric authority in the closest co-operation with the Rainfall Organisation and the Geological and Ordnance surveys, and independent of any interest concerned with the use or control of water. These views of the Committee are embodied in the conclusions set out at the end of the report, and full consideration has been given to the steps by which the work of the survey could be most expeditiously begun. The Committee has formed the opinion that it would not be feasible in the first instance, under present conditions, to move for the immediate establishment of an organisation to be financed by public funds, but rather that a beginning should be made in a comparatively small way, financed by subscriptions from individuals and bodies interested, with the prospect of being ultimately incorporated in a Government department. This cautious attitude on the part of the Committee is, we think, one which will meet with general approbation. From the small beginnings suggested, there may be evolved in time a valuable and widespread service commensurate with the Rainfall Organisation, which, our readers will remember, was for nearly sixty years carried on as an unofficial organisation, and was rightly described by the retiring director, Dr. Mill, when its records were handed over in 1919 to the State, as "having no parallel in any country."

There is no doubt that the position of inland water survey in the British Isles is at present far from satisfactory, and that some systematic survey of the water resources is urgently required. The comprehensive examination of the matter by the Committee emphasises this need, but no statement in general terms is likely to be effective in the absence of some definite proposal in regard to future procedure, and, with this in view, the Committee approached the Council of the Institution of Civil Engineers with the result that it received an intimation that the Council will be prepared, if it is so requested by the British Association, to appoint a committee to investigate the feasibility of carrying out the objects outlined in the report on a self-supporting basis. We understand that such a request has now been made by the British Association. The Floods Committee of the Institution has already drawn attention in its first report to the paucity of available records in the British Isles of river and stream gaugings and to the desirability of an organisation for inland water surveys. The setting up of an Institution committee to deal with this problem of organisation seems to us to be the most practical step, which, in the circumstances of the present time, could be taken.

Literature.

Elements of Industrial Heat. Vol. I. By John A. Randall and J. Warren Gillon. London: Chapman and Hall, Ltd. 1933. Price 16s. 6d.

As a first textbook on heat for engineering students, this volume is to be commended. The aim of the authors has been to provide, as a preliminary to any subsequent study of thermodynamical science, a good grounding in those elementary facts and principles which are sufficient for simple calculations. This we believe to be a sound educational procedure. One does not begin to instruct a boy in arithmetic by teaching first the theory of numbers, nor to inculcate the laws of grammar before he can read and write with fluency. Similarly, the study of thermodynamics is best based on a previously acquired facility in manipulating figures concerning the simpler phenomena of heat. There are, indeed, as every engineer knows, few practical problems in connection with heat of which an adequate solution may not be obtained with no more than a knowledge of fundamental principles and a little simple arithmetic. It is essential, however, that the knowledge shall consist of a real understanding, and that it shall be expressible in figures with that readiness which only familiarity can give. The methods, perhaps, may be wanting in that directness or academic elegance which a fuller knowledge of thermodynamical theory would provide, but the results will be just as serviceable.

These remarks must not be taken to imply that the present work goes far enough to satisfy the needs of the ordinary engineer, for it does not, nor does it pretend to do so. It is an introductory textbook and nothing more. But it certainly gives the student a start in a practical direction by its constant implication, enforced by many hundreds of examples and exercises, that the object of his learning is to be able to arrive at numerical results. It opens with a chapter on Temperature, Heat and Energy. The authors then discuss in turn calorimetry, the effect of heat on solids, liquids and gases, conduction, convection and radiation. A chapter is devoted to Fuels and Combustion, and another to the Properties of Air, with particular reference to air containing moisture. The final chapter deals with Energy Diagrams, and covers isothermal and adiabatic expansion, entropy and the Mollier chart. The Carnot cycle and the Second Law of Thermodynamics are not mentioned. The discussion throughout is elementary and the very minimum of mathematical knowledge is assumed. For example, the formulæ for the work done in isothermal and adiabatic expansion are given without proof, a footnote explaining that their formal derivation would require "more mathematical treatment than the scope of this text permits." Again, with the idea, presumably, of keeping even formulæ to the strict minimum, the student is taught to arrive at the temperature due to an adiabatic compression by the indirect way of first calculating the change in volume due to the change in pressure, and then finding the temperature from the Equation of State.

In all elementary textbooks such as the present one we think that beginners should be explicitly warned against the mistake of confusing the work required merely to compress gas to a given pressure in a cylinder, and the work which has to be done by a machine that has both to compress and to deliver it. The work of adiabatic compression alone is, of course, correctly given by the formula $(P_1 V_1 - P_2 V_2)/(n-1)$, which represents the area of the part of the indicator diagram lying under the compression curve. The authors certainly allow this fact to be inferred from their diagram, but most unfortunately they themselves fall into the error of employing the above formula in a calculation purporting to show the student how to obtain the work done by a compressor which has to deliver the air under pressure in the usual way. This process would, of course, require n times the power given by the formula. The slip is certainly one that needs correcting in any subsequent edition of the book. At the same time, the formula No. (49) on page 195 should be put right, besides being reversed in sign to conform to the alternative expression, to which it is said to be equivalent. These are the only two errors we noted, apart from a statement that Watt's experiments on the power of a horse were carried out in the seventeenth century.

The authors are to be complimented on expressing themselves clearly and in good English, an art in which most technical writers of the present generation fail so lamentably. They have therefore produced a book which is not only agreeable to read, but which is just the kind likely to be helpful to the apprentice or private students without mathematical knowledge. To such we cordially commend it, though with a certain regret that it does not carry them just a little farther, because the second volume which is promised will apparently be devoted to actual power plant machinery.

Office Administration for Manufacturers. By R. A. Mills, A.M.I.E.E., A.M.I. Mech. E. London: Sir Isaac Pitman and Sons, Ltd. 1933. Pages 408. Price 10s. 6d. net.

Before offering any comments on this book, it might be well briefly to indicate its general scheme. There are five main parts, of which the first, dealing with the General Office, consists of four chapters, which comprise the postal organisation, inquiries and quotations, orders, and finally publicity and price policy. The second part is devoted to the Works Office, again subdivided into four chapters, one being given to each of the following subjects; the production office, the inventory, costs, and buying. Part III. is special to the Drawing-office; and Part IV. to Accounting, a section in which is included a chapter, contributed by Mr. F. Rumsey, A.C.A., entitled "The Prevention of Fraud and Irregularities." Part V. handles the important item of Management, a separate chapter being allowed for statistics, for statistical graphs, for budgeting, and for market analysis respectively.

Mr. Mills emphasises the importance of organisation by pointing out that the overhead expenses may amount to three or four times the actual value of productive labour and material. We quite agree, and yet are convinced that many firms exist which, when confronted with the problem of introducing economies, almost instinctively begin with a suggestion to reduce the pay of employees, a consideration which might well come last.

It would be difficult to read a treatise on Administration without finding much food for thought, discussion, and criticism. As coming within the last category it is certainly desirable to draw attention to what may be regarded as serious omissions.

The author rightly preaches the necessity for close co-operation between the various activities of an organisation, but he does not clearly show us what he considers the relative importance of different functions, yet in the case of functional organisation, which he apparently has in mind, it is essential definitely to state the exact relationship that exists between the sections. This can very conveniently be explained by means of a "family tree," branching down from the managing director or general manager, with all the officials who are found on the same line horizontally held to be of the same administrative value as one another.

Again, it has been frequently affirmed that the success of an enterprise is largely dependent upon the maintenance of a well-organised estimating department, but on this side of the business the author is remarkably quiet. He certainly fully describes the method of making quotations, but it cannot be gainsaid that this is the easier part, and a satisfactory scheme for building up estimates for new work is a *sine qua non* in office adminstration. Similarly, a well-considered rate-fixing branch must be included in any modern system, and it is felt that Mr. Mills would be well advised to add a section on this subject, which at present he somewhat cavalierly brushes aside, in the chapter on the cost office, with the remark that "a ratefixer is an absolute necessity." It is to be hoped that he does not regard the ratefixer as part of the costing organisation.

We cannot let pass unchallenged such assertions as that "the accepted term in which to deal with overheads for estimates is as a certain percentage of direct labour." Though this may be one way, it is by no means the best, and many up-to-date engineering works are now using the machine-hour-rate method, which, as its name implies, is based on the hours that the machines work, and is not directly connected with labour charges.

It is suggested that no office administration is complete in a modern undertaking without a section set apart for dealing with problems of *personnel*, and it is hoped that notice will be taken of this in future editions.

The title of the last part of this book appears to be rather misleading, for should a busy manager pick it up, turn to the section entitled "Management," and scan it rapidly through, he would gain the impression that the author's conception of management was statistics and more statistics, graphs and more graphs! Now statistics, especially when rendered graphically, are invaluable assets from the managerial point of view, and Mr. Mills' treatment of the subject, as well as that of budgeting and budgetary control, is most helpful, but it should not be forgotten that half the remainder of his book is also concerned with the problem of management.

The foregoing criticisms must not be taken as evidence that this book is not to be recommended, but rather the reverse, for a constructive and suggestive work of this nature provokes discussion, and we are sure there are few who would not derive some benefit from a study of "Office Administration for Manufacturers."

Effect of High Winds on Grain Sheds.

By J. D. W. BALL, Assoc. M. Inst. C.E.

DURING the present century many experiments have been carried out at the National Physical Laboratory and elsewhere to determine the effect of wind on structures. Results recorded by Dr. Stanton indicated 91 miles per hour as the maximum velocity to be anticipated at the Tower Bridge site, equivalent to a maximum pressure of 27 lb. per square foot. These experiments at the Tower Bridge also indicated that, contrary to popular belief, the maximum pressure at any point is little or no greater than the maximum average pressure over a large area. The late Sir Benjamin Baker, observing that windows were not blown in by high winds, determined the breaking point of ordinary glass windows, and, from the results obtained, estimated that they would not bear a heavier pressure than 30 lb. per square foot.

It is interesting to compare these results with known cases of failure during violent storms, of sheds of light construction, used for the storage of grain in bags. In some of the stations of the Argentine Railways crossing the wheat and maize zones shed accommodation is required, covering a total floor space of 10,000 square metres or more, and in order to provide storage on this scale the sheds must for reasons of economy be of the very lightest construction and easily dismantled, as the variations of acreage under wheat or maize sometimes necessitate the removal of a shed from one station to another.

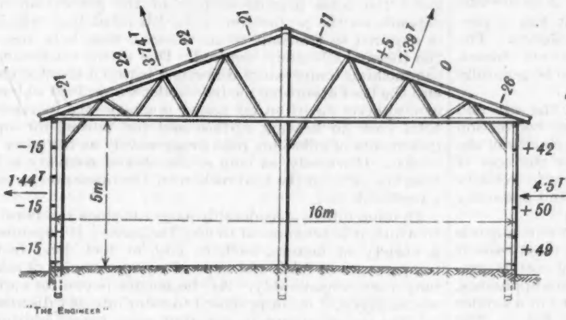

Fig. 1

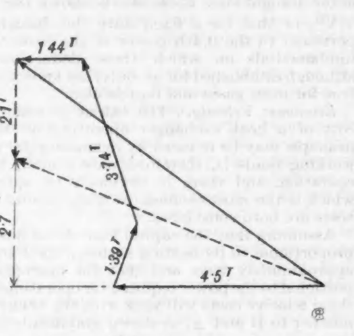

Fig. 2

A cross section of a usual type of grain shed is illustrated in Fig. 1. Sheds of this type are 16 m. wide and from 40 m. to 100 m. in length. The roof trusses are 4 m. apart, and are constructed of pitch pine, with 6in. by 3in. rafters, a pair of ties, each 6in. by 1½in., and diagonals 4in. by 3in. The trusses are carried on three 9in. by 3in. pitch pine columns, with hardwood bases. The purlins and side framing are 4in. by 3in., roof and sides being completely covered with galvanised corrugated iron sheets, secured with hammer-driven galvanised iron screwed nails, about 2½in. long and No. 14 gauge. The only openings are sliding doors and ventilation openings under the eaves. In August or September, when the equinoctial gales are at their height, it is not unusual for sheets to be loosened. Sometimes sheets and purlins are torn from the leeward side of the shed and from the leeward side of the roof, and carried away considerable distances, while many cases are on record of sheds being completely destroyed.

Experiments by Dr. Stanton on models of roofs were carried out with wind velocities varying from 10 to 20 miles per hour, equivalent to a maximum pressure of less than 1½ lb. per square foot. The suction on the leeward side of a roof with a 30 deg. slope and on the leeward side wall was never more than half the maximum pressure, but it would appear from the damage caused to the grain sheds that with stronger winds the effect of the suction on the leeward side is equal to, if not greater than, that of the pressure on the windward side.

An ordinary 8ft. corrugated iron sheet, covering an area of 13·7 square feet, has nine nails passing through it, but as four of these help to secure adjoining sheets, and each of the four corner nails help to secure three other sheets, each sheet is actually held down by four nails. In other words, the rows of nails are 3ft. 9in. apart across the roof and 11in. apart along the roof, so that each nail secures an area of 3·4 square feet. To extract one of these nails requires a steady pull of about 280 lb. Four nails should therefore require a force of 1120 lb. to extract them, which, divided by 13·7 square feet (the area covered by one sheet), indicates that a suction of 82 lb. per square foot would be required to loosen the sheets. The weight of the sheets and purlins is 2·5 lb. per square foot, so that the suction caused by the wind, when sheets are lifted, would appear to be equivalent to a steady pull of about 84·5 lb. per square foot.

The 4in. by 3in. purlins in continuous spans of 13ft. are frequently broken during severe storms. These purlins would be expected to break with a bending moment of 24 inch-tons, which, allowing for complete continuity, is equivalent to 1·85 tons per purlin, or 85 lb. per square foot. The suction has also to counteract the weight of the sheets and purlins, making a total of 87·5 lb. per square foot. If some sheets are loosened during a heavy wind, while others hold, any one purlin may have to resist the suction on a larger area than 13ft. by 3·75ft., so that the breakage of some of the purlins is no proof that the suction has reached this high figure of 87·5 lb. per square foot. Similarly, if one or more nails do not hold, there is an additional pull on those which do. Except in the outside lines, however, each nail is surrounded by eight others, so that the failure of one nail should not greatly increase the pull on the other nails.

In measuring the steady pull of about 280 lb. required to extract a nail, it is to be noted that with about half that pull a very slight jerk will loosen the nail, and this is an additional reason for doubting if the suction on the leeward side of a roof ever reaches such a high figure as 84·5 lb. per square foot. In Dr. Stanton's experiments on model roofs with winds of comparatively low velocity, the suction on the leeward side of a roof of 30 deg. slope never reached 50 per cent. of the maximum pressure on the windward side. Even if this maximum pressure is taken at as high a figure as 50 lb. per square foot, the suction would be less than 25 lb. per square foot, but, judging by the damage so frequently noted on the roofs and sides of grain sheds, the suction, if of this order, is evidently of such a violent nature that it must be considered as equivalent to a steady pull of very much more than 25 lb. per square foot. When a shed is only partially damaged, it is rare to find purlins broken on the windward side wall, which indicates that the direct pressure is of lower intensity, or that the damage caused by suction on the leeward side is possibly due to a proportion of the nails giving way and putting additional load on the purlins in which the nails have held.

Assuming that the distribution of pressure and suction, with high winds producing a maximum pressure of 50 lb. per square foot, is proportional to that obtained on models in a wind stream of low velocity, this distribution would be as shown in Fig. 1. With a suction of 22 lb. per square foot on the leeward side of the roof, the stresses in the members of the trusses are reversed, the rafters being in tension and the ties subjected to compression, but the stresses reached are not sufficiently high to cause failure.

The resultant forces on the roof and sides of one bay of the shed are also shown in Fig. 1, and are combined in Fig. 2, showing that there is a resultant force of 8·5 tons acting on each bay of the shed, inclined at an angle of 36 deg. with the horizontal, tending to lift the shed from the ground. The weight of one bay of the shed is only 2·1 tons, and the effect of this is also shown in Fig. 2, but to counteract the lifting effect of the wind each of the three columns must in addition to the weight provide an anchorage of nearly 1 ton, and failure to do this, especially when the bases are beginning to decay underground, probably explains the occasional complete collapse of a shed.

HEAT LIBERATION AND TRANSMISSION IN BOILERS.

Sir,—While I am in agreement with your report of the meeting at the Institution of Mechanical Engineers on the 17th inst., that the discussion on the paper which was then read was disappointing, I feel I must make some explanation to account for the way in which the paper was read.

Shortly before the appointed time I was informed that there would be allowed fifteen to twenty minutes for the reading of the paper, and in the time available it was impossible to compress the material contained in it into the number of words which could be spoken in that period; in fact, it is questionable whether it could have been done at all.

While appreciating the probable effect on the minds of those who had not had an opportunity previously to study the advance copy, it seemed that the only thing to be done was to read such extracts as appeared to make a more or less continuous line of argument.

As far as concerns at least one of those present, this attempt appears to have been a failure; but even now, after reviewing the paper, it does not seem possible even to have referred to the passages which were omitted and to make the matter referred to therein intelligible in fewer words than those used in the paper as it appears.

One is perhaps entitled to expect that anyone who goes to the trouble of attending a meeting of this kind will have made himself familiar with the matter which is to be discussed, by obtaining an advance copy of the paper.

E. W. Robey.

London, November 24th.

THE ENGINEER SALESMAN.

Sir,—The letter under the above heading, appearing in your issue of November 24th, is of considerable interest; the writer apparently is referring to home trade. From over twenty years' export experience, it is a matter of surprise to me that so few engineering firms employ engineers with commercial experience. I have found that if a quotation is asked for involving technical knowledge, the London office invariably has to refer the matter to the works. The engineer with commercial experience will see opportunities for increasing business which are completely missed by the purely commercial man. Undoubtedly the employment of the commercial engineer will not only lead to greater efficiency, but is essential for present-day conditions.

Export.

London, November 28th.

ROAD ACCIDENTS.

Sir,—May I, as one who has had considerable experience in driving on the Continent, where speed is and will remain, in the opinion of many, excessive, point out that the statistics published in *The Times* some time ago showed that the casualties in Paris were less than they were in London per thousand of population?

My experience convinces me that this is due not only to the crossings provided for pedestrians in which the latter have right of way, but also to the navigating rules adopted in France (and twelve other European nations), which, at cross roads would involve our giving priority to traffic coming from the left, instead of the convention here of giving way to traffic coming from the right.

The advantages of looking leftwards at cross roads are briefly these:—

It enables a driver to anticipate the movements of pedestrians about to step off the pavement near which one is driving.

It does not distract the attention from notices and warnings which are posted up on the left side of the road.

In emergency it gives one the width of a pavement and half the width of a road to pull up in after the priority traffic has been sighted, whereas looking to the right only gives about a pavement's width. This is of great importance in the case of encounter with the type of driver whom no amount of law and fines prevents from charging a cross road.

R. Douglas Archibald.

Devonport, November 25th.

OIL-ENGINED TUG FOR PERU.

On Tuesday, November 21st, there was launched from the Lowestoft yard of Brooke Motors, Ltd., the 45ft. oil-engined tug "Corona," which has been designed and built for the tanker mooring services of Lobitos Oil Fields, Ltd., on the Peruvian Coast. A preliminary run was made after the launch and on the following day official trials took place. The tug has proceeded to Amsterdam, where she will be loaded on a steamer for delivery to Peru, *viâ* the Panama Canal. A feature of the order, which was gained in the face of keen competition, both in this country and America, was the delivery of the vessel within nine weeks. The hull has a length of 45ft., a beam of 11ft., and a draught of 4ft., and a control house is arranged aft of the engine-room casing. Suitable provision is made for heavy towing bits and hooks behind the control position, but otherwise the decks are left clear for the expeditious handling of ropes and mooring lines. The propelling machinery comprises an 80 B.H.P., four-cylinder National oil engine, which also drives a small dynamo for lighting and auxiliary services. A 5 brake horse-power single-cylinder engine is placed in the port wing space and serves to start the main engine by means of a belt drive. The tug has a designed speed of 11 knots, and is strongly constructed and finished in a pleasing manner.

There is a rather fascinating story of a breakdown told in a paper read before the North of England Branch of the National Association of Colliery Managers by Mr. A. B. Hare. The pit at Throckley was drained by two electrically driven centrifugal pumps of 350 H.P. each. The reflux valve on one of the pumps burst, and the pump-room was flooded—on a Christmas Eve. The pump motors were put out of action by the flooding, but fortunately there was still in working order a steam pump fifty years old, that had not been used for ten years. It was got under way, and although it had to pump against a head of 350ft., cleared the pump-room, so that the electrical equipment could be repaired. The day after Boxing Day normal pumping was resumed.

Heat Liberation and Transmission in Large Steam Generating Plants.*

By E. W. Robey, M.I. Mech. E., and W. F. Harlow, A.M.I. Mech. E.

(*Concluded from page 532.*)

The Transmission of Heat.

General Principles.—At one time the view was held, and to some extent still persists, that the sole criterion of the capacity of a steam boiler to absorb heat depends on the extent of its heating surface. It is now well known that the amount of heat a given area of surface will transfer depends entirely on the manner in which it is arranged. Steam generators are successfully operating at the present time in which the fuel is burnt in a pulverised form which permits of the combustion chamber being entirely surrounded by water-cooled surfaces. In certain of these units as much as 63 per cent. of the total heat liberated by the fuel is transmitted to the steam and water by radiant heat. This arrangement presents certain definite advantages, inasmuch as the radiant heat surface serves the two-fold purpose of absorbing heat and forming furnace walls capable of effectively resisting the high temperature in the combustion chamber.

In other types of boilers, where refractory walls are employed, the heat is transferred almost entirely by convection. It is obviously impossible to transmit more than a portion of the heat to be received by an efficient steam boiler by radiation, and therefore much of the heat transmission at the lower end of the temperature range must be effected by convection. Even in designs such as those mentioned above, where more than half of the total heat is transmitted by radiation, the radiant heating surface is a comparatively small proportion of the total. This is because the rate of transmission by radiation is extremely high, due to the large temperature difference in the region in which this effect takes place. On the other hand, due to the comparatively low temperature differences prevailing where convection operates, the convection surface forms the major part of the total surface in the boiler. Even with the maximum amount of radiant heat surface the convection surface still represents more than 80 per cent. of the total. Therefore, in considering the size and cost of a steam generating unit from the viewpoint of the heating surface it contains, the extent of the convection surface is by far the most important factor.

Although the laws which govern the transfer of heat by radiation in boiler furnaces are somewhat obscure, it can be said that those governing convection heat transfer have now been definitely established, and can be applied in a fairly satisfactory manner to the problem of boiler design. An important difference between radiation and convection is that the latter effect can always be increased by increasing the speed at which the gases pass over the surface. Assuming a steam generator designed so that the furnace is completely water-cooled by tubes forming part of the boiler circulation system, one effect of reducing the furnace dimensions and increasing the rate of combustion over the fire bed would be to reduce the amount of radiant heat surface, and at first sight this might be thought a disadvantage.

It will be clear that with a smaller chamber the radiant heat surface will still receive the same total amount of radiant heat but at a greater intensity, as the surface is nearer the source of the radiation. It will therefore be more efficient. Quite apart from this, however, it is not disadvantageous to compensate for the loss of radiant heat surface due to the reduction of furnace volume, by an increase of convection surface by an amount dependent on the adopted gas velocities. Not only is the convection mode of heat transfer the most important effect in most boilers, but it is also the manner in which the heat is transmitted in the economiser and air heater.

Laws of Convection Heat Transfer.—That the amount of heat which a certain area of heating surface is able to receive from a moving gas depends on the speed with which the gas moves over the surface was first pointed out by Osborne Reynolds in 1874. More recently, in 1909, Dr. Nicolson showed the enormous advantage that could be gained by passing flue gases at higher velocities over the heating surface of steam boilers. Although little attention was paid to this for many years by practical engineers, the principle that the heat transfer is a function of the velocity is now widely recognised, and more recently many investigations have been carried out to establish the actual relationships that exist. These have resulted in numerous complex and somewhat divergent conclusions, but summarising the various opinions expressed the authors consider that the relationship

$$K=C_1V^{\frac{3}{4}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where K is the rate of heat transfer per unit area per degree of mean temperature difference between gases and surface, V the mass velocity of the gases moving over the surface (weight of gas per unit area of cross section of gas stream per unit time), and C_1 a constant, is of sufficient simplicity and accuracy to be the most suited for practical purposes.

Unlike the heat received by radiation, heat cannot be transferred by convection without some expenditure of energy to move the heating gases over the surface to which the heat is to be transmitted. Since the heat transfer depends on the velocity, and the energy loss also depends on the velocity, there must be a relationship between the heat transfer rate and the energy loss necessary to produce this effect. The energy loss is represented by the pressure drop or draught loss suffered by the gases in flowing over the heating surface, and this may be taken to vary as the product of the square of the mass velocity and absolute temperature. Thus

$$\Delta=C_2V^2T \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where Δ is the draught or pressure loss of the gases, V their mass velocity, T their mean absolute temperature, and C_2 a constant.

Here, again, some difference of opinion exists, but the authors find that the relationship given is confirmed in quite a satisfactory manner by practical results. The validity of both the fundamental equations (1) and (2) has been confirmed by the authors, not only by the operating results obtained from plants, but also by tests carried out with experimental apparatus.

Considering the significance of these relationships in the operation of heat-exchanging apparatus, it is clear that for a given extent of surface an increase in mass velocity increases the amount of heat transferred at the expense of draught loss. It is more important, however, to know the effect produced by changes of mass velocity on the extent of heating surface necessary and on the draught loss incurred for a heat exchanger that is to perform a given duty. In this case it must be assumed that a definite amount of heat is to be transmitted to or from a given quantity of fluid passing through the apparatus at a given rate.

The authors propose to take as an example a simple heat exchanger, and to assume a definite weight of air per hour to be cooled through a certain temperature range, and to ascertain the effect of varying the mass velocity V. As the total air flow is fixed the mass velocity can only be varied by increasing or decreasing the number of elements. Since the thermal duty also is fixed, all temperatures will be constant and therefore may be neglected. The length of the element will now vary, and since the friction loss through a pipe or duct is known to be proportional to its length the expression (2) previously established for draught loss must be modified by the introduction of a length factor. Thus let

$$\Delta=\text{constant } V^2L \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where L is the length of the element. From these relationships it can be shown that $H=\frac{\text{constant}}{\sqrt{\Delta}}$, or in words, that the heating surface varies inversely as the cube root of the draught loss. It can also be shown that $\Delta=\text{constant} \times V^{2\frac{1}{4}}$, or that for a fixed duty the draught loss is proportional to the 9/4th power of the mass velocity. The fundamentals on which these deductions are based, although established for air only, are known to be generally true for most gases and liquids also.

Economic Velocity.—The extent to which the size and cost of a heat exchanger operating on the convection principle may be reduced by increasing the velocity of the working fluids is, therefore, only limited by the cost of operation, and there is obviously an optimum velocity which is the most economical when capital and operating costs are both considered.

Assuming that the capital cost of the heat exchanger is proportional to its heating surface, which in most cases is approximately true, and that the operating cost is proportional to the power required for operating the apparatus, these relative costs will vary with the velocity in a similar manner to H and Δ, as shown graphically in Fig. 5. The summation of these two curves gives the total cost which at a certain velocity attains a minimum value. Obviously this velocity is the most economical value that can be adopted for any particular conditions. Since boilers, economisers, air heaters, superheaters, and feed heaters all operate on the convection principle, the above reasoning is applicable to any of these components of steam generating equipment, and although in the case of economisers and air heaters the laws given above appear to have received observance, in the case of boilers these considerations seem to have been seriously neglected. The present-day practice in boiler design is to arrange for gas velocities which result in a draught loss very little in excess of that which can be overcome by natural means, notwithstanding the possibilities of mechanical draught; and the intensity of the latter has been governed principally by the resistance imposed by economisers and air heaters.

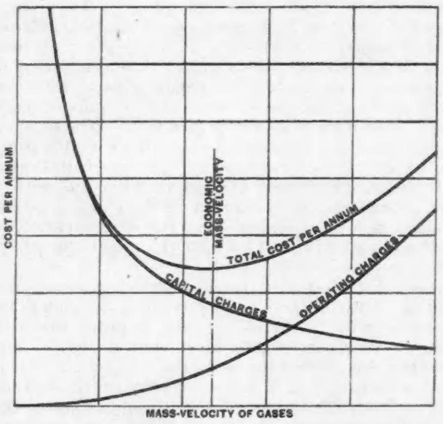

Fig. 5—*Variation of Relative Costs of Heat Exchanger with Fluid Velocity for given Thermal Duty.*

Capital charges are taken to vary as $H=C/V^{\frac{3}{4}}$.
Operating charges are taken to vary as $\Delta=C.V^{2\frac{1}{4}}$.

Applying the relationships established above to a water-tube boiler and neglecting the extent of radiant heat surface which, as already stated, constitutes only a small proportion of the whole, it should be possible to reduce the heating surface by 50 per cent. at the expense of an increase in the draught loss to eight times its normal amount. At present the usual practice is to design water-tube boilers with a draught loss of from ¼in. to ½in. of water. If the gas velocities in such boilers were increased so that the resistance through the passages was 2in. to 4in. of water the heating surface could be reduced by 50 per cent. This at first sight may appear to indicate an excessive demand for auxiliary power, but a little consideration will show that this increase is comparatively unimportant.

Considering a boiler of 100,000 lb. per hour evaporative capacity at 300 lb. per square inch pressure, 700 deg. Fah. steam temperature, and 250 deg. Fah. feed temperature, the gas quantity would be approximately 160,000 lb. per hour, or 51,000 cubic feet per minute at 300 deg. Fah. Assuming the draught loss through the boiler is increased from ½in. to 4in. of water, and that the overall efficiency of the induced draught fan and motor is 50 per cent., the power required to overcome the increase in resistance would be 42 kW. Taking a station efficiency of 20 per cent., the heat equivalent of this power expenditure would be 0·52 per cent. of the total heat input to the plant. Hence the effect of decreasing the heating surface and therefore the capital cost of the boiler, would be a loss in efficiency of only 0·5 per cent., or conversely, the advantage gained by doubling the size and cost of the boiler, thereby keeping the auxiliary power low, is merely to increase the efficiency by this amount.

In cases where fuel is cheap and the load factor low the increase in the capital cost of a steam generating unit incurred by the adoption of air heaters and economisers in order to obtain high efficiencies is frequently considered unjustifiable. In such instances it would probably be found more profitable to reduce the cost of the boiler by increasing the gas velocities and to utilise the money thus saved for the provision of an economiser and air heater, thus increasing the efficiency at no increase in cost.

In most types of boilers in common use the gas velocities are far below the true economical value, and much of the draught loss that occurs is caused by changes of direction in the gas stream and is not productive of heat transfer. To be efficiently utilised the draught loss should arise entirely from frictional resistance through the tube banks, and, since the heating surface can be reduced at the expense of draught, wasted resistance is tantamount to an unnecessary increase of heating surface. It appears that the possibilities of reducing the heating surface of water-tube boilers by using higher gas speeds which are made possible by the introduction of mechanical draught, have not been fully explored and that considerable advances are possible in this direction.

Stack Temperature.—For any given velocity of flue gases the total heating surface of the generating unit depends on the proportion of the liberated heat which it is required to transmit to the steam; that is to say, on the thermal efficiency required. Due to the continuously diminishing temperature difference between the flue gases and the heat absorbing media—boiler water, feed water, or atmospheric air (if an air heater is used)—the increase in total cost (in heating surface and fan power) for equal increments of efficiency rises progressively as the gases are cooled. Obviously, as long as the cost of recovery is less than the value of the heat reclaimed, the operation remains a profitable one.

Opinion differs considerably as to the stack temperature to which it is economical to cool the gases; it depends on a variety of factors, such as cost of fuel, load factor, temperature of feed, and type of equipment, all of which may vary considerably. As the matter is one for careful cost analysis, it is not proposed to enter into any discussion on this point, except to say that since every additional 30 deg. that the gases are cooled represents a reduction of the fuel bill by approximately 1 per cent., very considerable expenditure can be justified to obtain low temperatures.

In British power station practice the limiting temperature is generally considered to be 250 deg. to 300 deg. Fah., but in America the present trend is towards considerably higher temperatures of 350 deg. Fah. and upwards. It may be said that in most steam generating plants in this country a stack temperature of 250 deg. Fah. can be easily justified from considerations of economy, providing a suitable arrangement of plant is adopted.

Air Heaters.—The recognition of the above has led to the general adoption of air heaters, without which such low temperatures are quite impossible. Even where the desired stack temperature is considerably above this figure an air heater is usually essential, as the relatively high temperature of the feed when heated by bled steam makes it impossible to cool the gases sufficiently by the economiser alone. Further, and apart from the above considerations, air heater surface is generally cheaper to install and maintain than economiser surface, even when the lower rate of transfer in the air heater is taken into account. As previously stated, the extent to which air heater surface can replace economiser surface is limited in mechanically fired plants by the effect of the heated combustion air on the fuel bed, but the use of a large proportion of secondary air will considerably raise this limit. In general, and assuming there are no limitations to the temperature at which the air may be used in the combustion process, the greater the extent to which air heater surface replaces pressure surface, the cheaper will be the complete generating unit, providing such air heater surface is used to the best advantage.

In considering the temperature range through which it is possible to cool the flue gases by air heating, due regard must be given to the heat capacity of the air compared with that of the flue gases. Since the quantity and the specific heat of the flue gases are each greater than the corresponding quantity and specific heat of the combustion air, the rate at which the gas cools is always less than the rate at which the air is heated. That is to say, the ratio

$$\varphi=\frac{\text{temperature rise of air}}{\text{temperature fall of gases}} \text{ is always greater than 1.}$$

In an ideal plant this ratio should be about 1·1, but in practice it is usually not less than 1·25 and frequently much higher. Hence the difference between the temperature of the stack gases and the atmospheric air which exists at the cold end of the heater progressively diminishes as the air becomes heated. The heating surface therefore becomes less effective until a stage is reached where any further increase of heating surface becomes uneconomical. For the comparatively small range of temperatures through which it is customary to cool the flue gases by air heaters in plants fired by mechanical stokers this effect is not sufficiently marked to merit special consideration, but when high preheated air temperatures combined with low stack temperatures are desired, as in pulverised fuel or oil burning installations, the matter becomes one of considerable importance.

For example, assume a stack temperature of 250 deg. Fah., preheated air at 700 deg. Fah., ambient air temperature at 100 deg. Fah., and $\varphi=1{\cdot}25$. The drop in gas temperature through the heater would have to be $\frac{(700-100)}{1{\cdot}25}=480$ deg. Fah. The gas would therefore have to enter the air heater at (480+250)=730 deg. Fah. The temperature difference between the air and gas consequently would be only 30 deg. Fah. at the hot end, although 150 deg. Fah. at the cold end. The amount of heating surface necessary to effect the heat recovery under these conditions would be entirely disproportionate. In such cases a much more effective temperature difference could be maintained between the air and gases by introducing a small economiser or feed heater between two sections of air heater at a suitable point in the temperature gradient, thus reducing the heating surface to economical proportions.

---

* The Institution of Mechanical Engineers—Abridged.

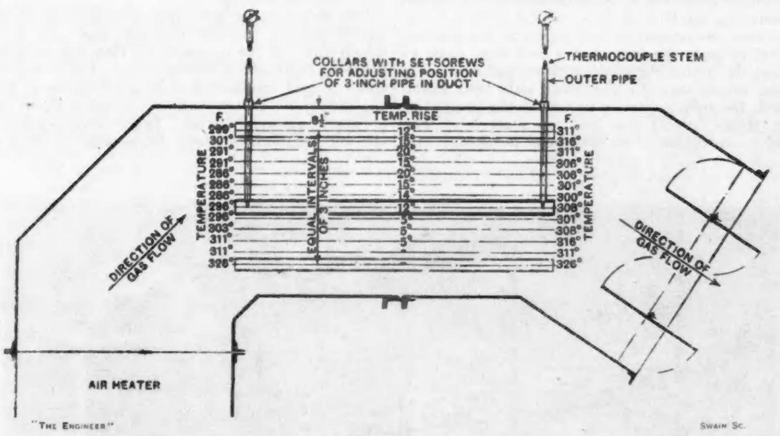
It will be obvious from the foregoing that the value adopted for φ bears an important relation to the area of heating surface of an air heater which is necessary to produce any desired temperature reduction in the flue gases, and the accurate assessment of this factor is essential if the designed results are to be realised. At first sight it may appear that the estimation of this factor is quite a simple matter, as the relative weights of air and gas are easily calculable and their specific heats well known, but experience shows that values much higher than those obtained from the above considerations are possible. Clearly, if a heater is designed on a basis of $\varphi = 1 \cdot 2$, and in practice $\varphi = 1 \cdot 5$, the final gas temperature will seriously exceed the expected figure, since the capacity of the air to reduce the gas temperature has been over-estimated.

The existence of this apparent discrepancy in the thermal balance of an air preheater has for some time been recognised, but was always attributed to a deficiency in the air quantity actually passing through the heater.

The obvious remedy was to construct plants in such a manner that no air other than that passing through the air heater could gain access to the furnace, but despite the meticulous care with which modern steam generating plants are designed to attain this end, the disparity still persisted. It was then considered that the discrepancy was due to inaccurate temperature readings, and for this reason the authors obtained extremely sensitive thermocouples by means of which radiation effects could be eliminated. These not only confirmed the figures previously found, but their greater sensitivity rendered possible accurate exploration of temperature across any section of the gas and air ducts. From these readings it was found that there appeared to be actually an increase in temperature in the gases after leaving the air heater. It was considered, therefore, that the discrepancy could only be explained by the liberation of a certain amount of latent heat in the flue gases during their passage through the air heater, and realising that the problem was one which called for expert analytical investigation, they invited Professor M. W. Travers, F.R.S., to make a research into the matter.

By the use of very exact methods, Dr. Travers showed that an increase in CO_2, in some cases a decrease in H_2, and a corresponding decrease in O_2, occurred in the flue gases passing through the air heater, and that the latent heat of combustion that would result from such changes would fully explain the discrepancy between the temperature rise of the air and the fall in the gases.

More recently the authors have carried out further investigations into the temperature rise in the gas stream leaving the air heater, by introducing a tube with thermocouples at each end, as shown in Fig. 6, thus removing any doubt that might be entertained with regard to their original figures when the duct was merely traversed. The results show that even in a distance of 7ft. the gas temperature rises by as much as 20 deg. Fah. It would appear that given the requisite conditions for the air and combustible gases to associate, combustion often proceeds in the gas stream beyond the flame, and this may take place even at temperatures as low as 300 deg. Fah.



"The Engineer" Swain Sc.

Fig. 6—*Method of Measuring Temperature Rise in Gases Leaving Air Heater.*

Tests results show that this phenomenon is quite commonly in evidence and that it is not confined to any particular make or type of air heater, boiler, or combustion equipment. The only conclusion that may be drawn from comparisons of equipment would appear to indicate its absence in oil-fired generators. In certain plants of every type there is no evidence of such action, and in the authors' view this is probably because of the prompt manner in which the combustion in the furnace is brought about by better association of the air with the combustible gases in correct proportions. It is significant that in cases where combustion has appeared to be smoky, this phenomenon has usually been evident. The apparent discrepancy in the heat balance not only occurs with air heaters, but is frequently found to exist with many economisers and undoubtedly can be explained in a similar manner.

To render the heating surface not only of the air heater and economiser, but also of the complete steam generator, fully effective, the heat should all be released before the convection process of heat transfer commences. Any heat liberated during the passage of the gases over the convection surface tends to lower the efficiency of this process. It has been a noticeable fact that in plants where secondary air has been liberally and efficiently applied an appreciable reduction has been made in the stack temperature.

Dew Point Effects.—One of the chief problems that has been encountered in obtaining low stack temperatures by air heaters has been that of avoiding the harmful effects resulting from condensation of the moisture in the flue gases on the air heater elements. No air heater will operate satisfactorily if the plates are periodically or continuously wetted whilst in operation, as not only does this cause adherence of the flue dust which obstructs the gas passages, but the combination of the moisture with the sulphurous gases in the products of combustion causes the formation of corrosive sulphuric acid, which rapidly attacks the elements. The matter is one on which misconception exists, due in a great measure to lack of exact data on the dew point temperature of flue gases. Until quite recently no reliable information on this subject was available.

Since air heaters have been introduced various means of meeting dew point trouble have been adopted, and most of these seek to remove the effect rather than the cause. Until the last year or two, no serious attempt appears to have been made to get to the root of the trouble by stopping the formation of dew.

The only attempt that appears to have been made to prevent condensation was to limit the temperature to which the gases were reduced by the air heater, as it was generally considered that condensation depended entirely on the gas temperature. Notwithstanding that in some cases dew point trouble was experienced with gas temperatures of 350 deg. Fah. and over, and that in other cases with temperatures of 230 deg. Fah. the trouble was absent, this view was still commonly accepted, and the difference of behaviour referred to was frequently explained by the virtues of the type or make of the air heater. In certain installations with which the authors were concerned a few years ago, this trouble was so acute, even with gas temperatures of 300 deg. Fah. and upwards, that it was obvious that the prevailing notions on the subject were fallacious, and a thorough investigation of the whole problem became necessary.

It was recognised, of course, that in order to maintain the plates of an air heater or any other cold surface free from moisture, it is necessary to keep the temperature of the surface at or above the dew point temperature of the gases. If the temperature of the wall of an air heater element is the mean of the temperatures of the air and gas on either side, then with the plant in question the minimum temperature would have been well above the theoretical dew point temperature. For example, with gas leaving at 300 deg. Fah. and air entering at 80 deg. Fah., the minimum plate temperature would be 190 deg. Fah. The dew point as calculated from hygrometric tables would be approximately 100 deg. Fah. (for coal with 10 per cent. moisture, 4 per cent. H_2, and 13 per cent. CO_2 in the flue gases). Nevertheless, the condensation on these air heaters was so rapid that the elements were simply dissolving away.

A closer examination of the problem showed that this accepted theory of the temperature of the wall was fallacious, because it presupposed equal rates of transfer from the gas to the metal, and from the metal to the air, which in practice do not occur throughout the element. There are several reasons why this assumption is not justifiable.

Even if it were possible to calculate the plate temperature from the relative temperatures of the air and gas, it is extremely difficult to estimate the lowest gas temperature that may be experienced because this fluctuates between wide limits.

The foregoing considerations, combined with their experience in this matter, led the authors to conclude that the only practical way to ensure that the lowest temperature of the heater elements was above the dew point temperature of the gases was to maintain the temperature of the air entering the heater at, or closely approaching, this temperature. In general, the results obtained by the application of this principle have greatly exceeded expectations, as by this means it is possible not only to prevent any deterioration whatsoever of the elements, but there is a considerable increase in heat transfer and definitely no falling off whatever of the heat efficiency, even after long service. Further, in most cases where these conditions are carefully maintained, the problem of cleaning the heater is practically eliminated. All that is necessary is a periodic blowing-out by compressed air.

Of course, these advantages are not obtainable without some extra cost, as means must be provided to increase the initial air temperature to the desired figure. Usually the most convenient method is to recirculate a portion of the preheated air through the forced draught fan, the amount necessary depending on the temperature of the air supply, the temperature of the preheated air available, and the dew point temperature of the flue gases from the particular fuel used. Obviously this involves an increased load on the fan, but the cost of this power is negligible compared with the saving in maintenance and efficiency, due to the improved condition of the heater. (Usually the heat equivalent of the total forced draught fan power is of the order of ¼ per cent. of the fuel. Assuming the recirculation increases this power by 20 per cent., the heat equivalent of this increase would be 0·05 per cent. of the heat input to the plant. This represents approximately the same heat loss that would be brought about by an increase of 2 deg. Fah. in the stack temperature. An air heater becoming dirty will elevate the temperature of the stack gases by 20 or 30 deg. in a very short time.)

If sufficient consideration is given to the arrangement of the plant in the design stage, so that the air supply to the forced draught fan is comparatively warm, the increase in fan power necessitated by recirculation will be greatly reduced, if not eliminated. The ambient air temperature in a boiler house may vary as much as 50 deg. Fah. at different points, and in the interests of the general efficiency of the unit, as well as that of the air heater, the position of the air intake should be such that the heat which must be radiated from the generating unit is reclaimed and returned to the system. As the air is introduced at a higher temperature than previously, one might imagine that this system of recirculation reduces the thermal efficiency of the air heater. In practice this is not the case, probably because the higher temperature of the air is offset by the greater quantity which is passing through the heater.

Soot Blowers.—An important consideration affecting the dew point of the gases which is often overlooked is that any steam or water used in the combustion process materially raises the dew point temperature and therefore increases the liability for moisture to be deposited, not only in the air heater, but also in the stack. The same effect is produced by the use of steam soot blowers for cleaning the boiler and economiser surfaces. The amount of steam injected into the flue gases by soot blowers varies considerably with the type of blower employed, but frequently the difficulty of keeping the boiler and superheater surfaces clean necessitates the use of an amount of steam that is sufficient to raise the dew point temperature as much as 50 deg. Fah. or more. Actually, dew point temperatures of 175 deg. Fah. and upwards have been registered while soot blowers were being operated, and precautions should be taken to see that either the air entering the heater is raised to a temperature approaching this figure, or, failing this, the air should be excluded from the air heater whilst the soot-blowing operation is carried out.

In some cases soot blowers are situated in a region of low gas temperature close to the air heater. It is possible that when steam (either superheated or saturated) is expanded to atmosphere through the soot blower nozzles, it will become wet, due to the heat drop experienced. If this moisture is not re-evaporated before reaching the air heater elements, it will be deposited, regardless of their temperature. Any water thrown out by the blower by reason of inadequate draining will, of course, act in a similar manner. In such cases the only remedy appears to be compressed air blowers; in fact, having regard to the possible ill effects of moisture in the flue gases in raising their dew point, the authors are strongly in favour of air blowers for all boiler-cleaning purposes.

FORESTRY AIDS EMPLOYMENT.

A project to transform seventy-eight square miles of forest near Colter's Landing, in the province of New Brunswick, into a model experimental forest area for the Maritime Provinces is part of a great and increasingly successful governmental co-operative scheme for solving the problem of caring for thousands of single unemployed men throughout the Dominion. The Maritime plan was made possible in the first place by the action of the New Brunswick Government in setting aside the large forest area for other than commercial purposes. The scheme is primarily and essentially a relief scheme. When the plan was formulated by the Department of National Defence in the autumn of 1932, a modest start was made with the employment of 2000 single men on the clearing and grading of intermediate landing grounds on the Trans-Canada Airway; on repairs to the old fortifications at Halifax and Quebec, and on the construction and improvement of air stations at several other points. With a steady expansion of the plan, it is now capable of employing at least 20,000 single men. At the present time the Department of National Defence is supervising projects in British Columbia on which about 7000 young men are employed. Another large forest scheme in Manitoba is providing useful productive employment. In the Duck Mountain district of that province, 50 square miles of land have been given to the Government of Manitoba for the development of an experimental forest area to provide information in respect to the important spruce forests of Northern Manitoba and Saskatchewan. Coming east into the north-western area of Ontario, a large amount of employment is provided by the clearing of the foreshore of the Lac Seul reservoir, in co-operation with the Governments of Ontario and Manitoba. This work will make available when completed an additional head of 12ft. for the English and Winnipeg rivers power plants. In this case the benefit of the work will be transmitted directly to the users of electric current. Most of the projects for the relief of single men are administered, and the works are carefully supervised, by the military district in which they are situated. For the preparation of plans and specifications, the Royal Canadian Engineers are held responsible, while the Army Service Corps provides the transportation and feeding facilities. Clothing and equipment are issued by the Ordnance Corps, while sanitation and medical attention are provided by the Medical Corps.

Steels for Use at High Temperatures

(See also page 542.)

THE following statement by the investigators of the British Electrical and Allied Industries Research Association on the results sought and achieved in the Research on Steels for High Temperatures is dated November 10th, 1933 :—

An intensive and comprehensive research upon steels for high-temperature service has been proceeding for the past three or four years under the direction and control of the Joint Committee representing the British Electrical and Allied Industries Research Association and the National Federation of Iron and Steel Manufacturers.

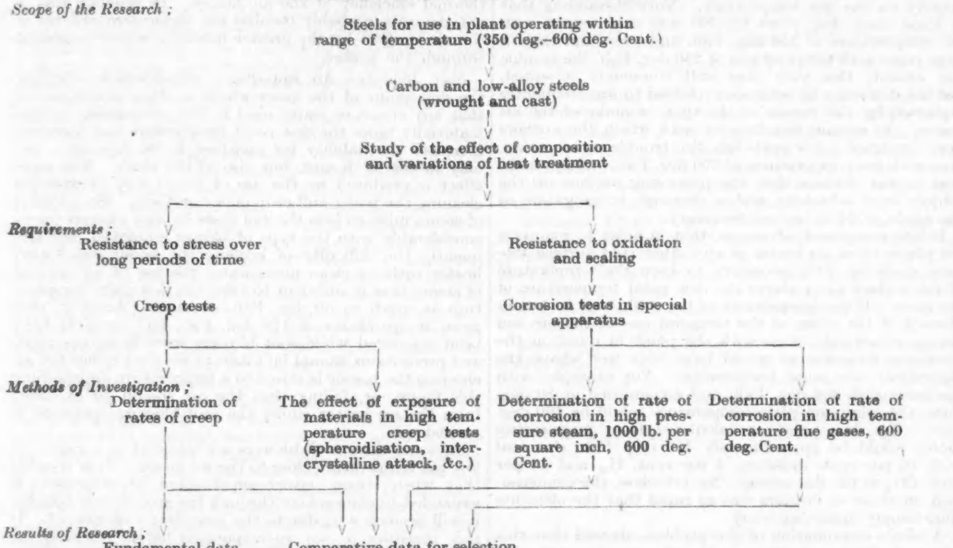
The research, which has been carried out at the National Physical Laboratory, has two main activities, viz.:—

(1) To explore the properties of various low alloy steels with a view to providing authoritative guidance in their better utilisation for high-temperature service.

(2) To examine the possibilities of improvement of selected steels by the addition of various elements considered promising.

In the case of both activities two lines of investigation are involved. These are concerned with (*a*) mechanical properties, and (*b*) resistance to scaling and oxidation under conditions which occur in service.

STEELS FOR HIGH TEMPERATURE SERVICE.



Scope of the Research ;
Steels for use in plant operating within range of temperature (350 deg.–600 deg. Cent.)
Carbon and low-alloy steels (wrought and cast)
Study of the effect of composition and variations of heat treatment
Requirements ;
Resistance to stress over long periods of time
Resistance to oxidation and scaling
Creep tests
Corrosion tests in special apparatus
Methods of Investigation ;
Determination of rates of creep
The effect of exposure of materials in high temperature creep tests (spheroidisation, intercrystalline attack, &c.)
Determination of rate of corrosion in high pressure steam, 1000 lb. per square inch, 600 deg. Cent.
Determination of rate of corrosion in high temperature flue gases, 600 deg. Cent.
Results of Research ;
Fundamental data for design
Comparative data for selection of steels for service

In order to obtain critical data for a basis of comparison with alloy steels an investigation of the behaviour of a series of carbon steels (0·15 per cent., 0·4 per cent., and 0·6 per cent. C.) has been undertaken. The unusual behaviour of at least one of these steels at 450 deg. Cent. necessitated the study of a large number of carbon steels, and a consideration of the effect of structural conditions in those steels. It has been found that rolled carbon steels of approximately the same composition and heat treatment may vary considerably in their resistance to creep at 450 deg. Cent., and that the resistance to creep of carbon steels does not necessarily increase with increase in carbon content from 0·15 to 0·4 per cent. Attention is being given to an examination of the extent to which variations in the conditions of manufacture of carbon steels affect their resistance to creep.

Important investigations are being carried out into the properties of low alloy steels, notably plain molybdenum steels and complex molybdenum steels. The results of the initial work on commercially produced steels containing 0·15 per cent. C and 0·4 per cent. C with additions of 0·5 per cent. Mo and 1·0 per cent. Mo showed the extent to which the presence of molybdenum improved the creep resisting properties of a steel.

Considerable progress has been made in exploring the influence of thermal treatment upon these important steels, and the work demonstrated that if their high resistance to deformation at elevated temperatures is to be utilised, their thermal treatment is of great importance. The heat treatments have been applied to the steel after a consideration of the data derived from the study of transformation temperatures and microstructures. It has been shown, however, that these plain molybdenum steels failed with comparatively low elongation owing to intercrystalline cracking, when subjected to fairly high prolonged stresses at 550 deg. Cent. Various heat treatments were applied to these steels, but the results of tests have not so far indicated that intercrystalline cracking can be entirely eliminated by adopting a particular heat treatment. Tests are in hand to determine whether intercrystalline fracture is likely to be associated with the very small rates of creep permissible in steam turbine plant. It has been shown that the impact resistance of the low-carbon molybdenum steels has not been impaired by prolonged heating at 450 deg. Cent. and 550 deg. Cent.

Steps are now being taken to discover what element or elements, added in small percentages to molybdenum steels, will eliminate intercrystalline cracking at 550 deg. Cent., without appreciably diminishing the very favourable creep-resisting properties resulting from the presence of molybdenum.

In the meantime it has been established that the addition of copper up to 0·5 per cent. to carbon steel provides no improvement in regard to resistance to creep at 450 deg. Cent., but in the presence of other elements copper may have a beneficial effect.

The study of the creep properties of the steels enables data to be accumulated for the design of plant, but considerations of certain service conditions indicate that the steels must also withstand oxidation and attack by superheated steam and flue gases. The resistance to attack is a problem which is capable of being solved by experimental means and suitable apparatus for the study of this problem has been put into operation. The attack of superheated steam is being investigated in a high-pressure reaction vessel capable of maintaining specimens of the steels at 600 deg. Cent. under a pressure of 1000 lb. per square inch. The study of the attack of flue gases has been investigated on various steels in flue gas mixtures containing sulphur dioxide. Two methods have been put into use; the first consists of an examination of wires, the decay being noted by decreases in the electrical conductivity and tensile strength, and in the second method the nature of the attack on massive specimens has been studied in view of the protective action of initial oxide layers.

The scope of the research will be clear from the annexed diagram. One of its main objects is the determination of conditions of material and treatment which will make it possible to increase operating temperatures by one or two hundred degrees Fahrenheit.

The investigations have now reached a stage at which tangible results are being obtained. The subject is of importance to the engineering industry on account of the steady increase in operating temperatures and pressures which characterises modern practice, whilst, although the quantity of steel concerned is not large in comparison with the total output, the fact that a user may have to go abroad for the latest developments in materials is a fact of great importance to the steel industry, which urgently needs the fullest information as to the properties required in these special qualities of material. The British steel industry owes its foremost position to its pioneer character and technical superiority, and it is important that it should maintain that position in such special departments as that of materials for high temperatures.

It may be emphasised that very close contact is maintained between the work of the Committee and that of the D.S.I.R. High Tension Committee. The latter Committee is concerned not only with the investigation of the properties of existing commercial materials at high temperatures, but with the exploration of the fundamental aspects of the subject. Reports on this work have been, and are being, published. These reports have obtained a wide circulation among engineers and others vitally concerned with the properties of metals at elevated temperatures. On account of the authoritative character of the data presented they have formed the basis of design of such parts as steam generators and superheaters, steam piping and fitting, and important steel forgings and castings required for service in steam power plant, and other equipment operating at temperatures at which the phenomenon of creep becomes of prime importance. In providing a basis for the rational design of parts in carbon steels for employment at elevated temperatures, these reports have contributed in no small measure to the important position occupied by British engineers and steel manufacturers in the construction of steam power and other plant operating at elevated temperatures.

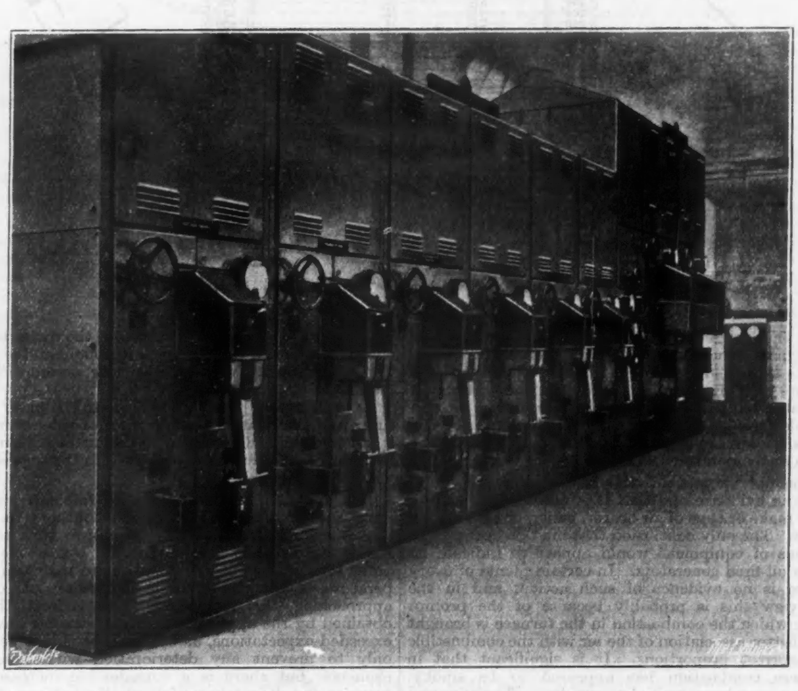
Heavy Current Switchgear.

A LOW-VOLTAGE, heavy current switchgear installation possessing special features has been carried out by Ferguson, Pailin, Ltd., to the order of the Central Electricity Board. It controls the output of two 4000-kVA transformers, which provide the supply from the "grid" to J. and P. Coats, Anchor Mills, Paisley, and although the equipment is of a somewhat unusual character, the contract was completed within eight weeks. Another contract has since been placed with the same firm by the Central Electricity Board for a similar low-tension installation for controlling three 6000-ampère incoming supplies from the "grid" to a second mill belonging to J. and P. Coats, Ltd. In this case the original generating plant is being retained, and it is to be operated by the Central Electricity Board as a selected station.

The new switchgear that is now in operation is shown in the first of the accompanying illustrations, from which it will be seen that it is of the cubicle type. There are two incoming 5000-ampère panels and six hand-operated, 2000-ampère panels, controlling outgoing feeders to the factory. The three-phase rupturing capacity is 80,000 kVA with a corresponding "making" current or an initial value of fully asymmetrical short-circuit current of approximately 300,000 ampères. The electro-magnetic effects of this current naturally give rise to considerable forces, the repulsive force on the terminals of the round circuit breakers installed in the incoming feeder cubicles being in the neighbourhood of 13,000 lb. The short-circuit current also applies a downward "throw-off" force to the moving contact bars of approximately 6000 lb.

The operating mechanism and electrical conductors of the breaker, which is shown in the second illustration, are designed to have an adequate factor of safety under short-circuit conditions, while the solenoid closing mechanism develops sufficient power to make a contact of adequate area and to compress the "kick-off" springs sufficiently before the closing movement is reversed by mechanical tripping of the breaker, thus preventing the possibility of the contacts welding in.

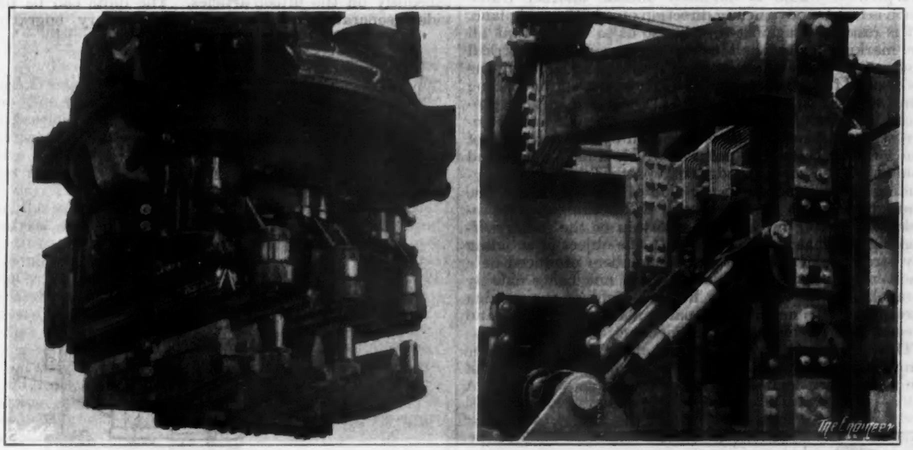
The full floating self-aligning main contact fingers and the V-shaped moving contact bars are silver-plated, which obviates the necessity for frequent cleaning without lowering the surface conductivity. The arcing contacts of the rose and candlestick type are capable of dealing with the maximum current which can occur when the breaker is closed on a short circuit. In the outgoing feeder cubicles the 2000-ampère breakers are similar to those described.



80,000 - kVA, 525 - VOLT CUBICLE SWITCHBOARD

All the breakers are enclosed in round steel welded tanks, which are almost entirely fabricated. A special truck equipped with tank raising and lowering mechanism serves for removing the breakers.

The cubicles contain 5000-ampère bus-bars and connections of the same capacity are provided in the incoming cubicles. Provision is made in the heavy current cubicles and bus-bar chambers to prevent overheating and mechanical ailure due to the normal and short-circuit current, which, with an initial asymmetrical value of 300,000 ampères, results in a repulsive force of over 2000 lb. per foot run. Ventilators are provided at the top of the cubicles and ventilating louvres on the front and rear doors. All inner horizontal screens are composed of perforated aluminium, which, while permitting free natural ventilation, also minimises local heating due to eddy currents. Portions of the cubicle structure in proximity to heavy current conductors are constructed on non-magnetic steel angles and complete magnetic circuits around conductors are thus avoided.



5000 Ampere Breaker Contacts and Main Connections

Current transformers for metering and for the protective gear are provided in the 5000-ampère incoming panels, and special precautions are taken to minimise the effects of interaction between transformers. All the main conductors which are braced by bronze clamps to withstand the forces developed by short-circuit currents, work at a maximum current density of 500 ampères per square inch. The bracing mentioned is supplementary on the bus-bars to the insulated bus-bar supports.

The lay-out of all the apparatus has been designed with a view to convenient operation with a simple run of main conductors. The bus-bar isolating switches to be seen in the third illustration are gauged and operated by an external hand wheel through a chain drive and worm reduction gearing, the usual indication and padlock arrangements being provided. A separate chamber accommodates the potential transformer, whilst its fuses on the primary side are mounted behind a separate hinged panel, which enables the fuses to be removed and replaced safely without interfering with the main equipment.

Bare copper conductors run at a maximum current density of 500 ampères per square inch, form the main connections between the power transformer control panels and the transformers themselves. They are carried on insulated blocks from a steel supporting structure and are enclosed by expanded metal screens. Bronze clamps serve to brace these connections in a similar manner to the switchgear bus-bars in order that they may withstand the short-circuit forces. With the phase spacing adopted for the connections, the maximum force is in the neighbourhood of 2500 lb. per foot run, and in designing the bracing clamps an ample factor of safety was allowed.

The consulting engineers for the work were Messrs. Kennedy and Donkin.

Telephone Interference.

Recent investigations on telephone interference are described in a paper by Messrs. W. G. Radley and S. Whitehead, presented at a meeting of the Institution of Electrical Engineers on Thursday, November 23rd. The subject is roughly divided under two heads—disturbance from harmonics during normal operation of the power system, and danger due to excessive induction at the fundamental frequency under transitory fault conditions. The former gives rise to noise and with regard to its disturbing effect may be calculated or measured in terms of E.M.F. at 800 cycles per second. In the same way the total harmonic output of electrical plant may be expressed by its telephone interference factor. For modern installations this quantity can usually be kept below 1 per cent.

Although mercury arc rectifiers exceed this value, the telephone interference factor can be reduced to less than 1 per cent. by appropriate smoothing equipment. Both disturbance and danger are generally due to induction from earth currents. The magnitude of the current is investigated for various cases, and it is shown that the earth current can be calculated if the earth resistivity is known. Alternative methods of measuring this are available. The screening effect of conductors in parallel (such as telephone or power cable sheaths, earth wires, and rails) must be taken into account, and formulæ and experimental measurements are given for these.

Indications are given in this paper as to how various types of interference may be decreased, as by the suitable choice of generators and transformers, neutral impedances and filters, output filters, additional earth wires, the use of power cables or telephone cables instead of overhead circuits, the design of cable sheaths, balancing of communication circuits, the choice of earthing methods, &c. The decision as to the appropriate method rests upon many considerations of cost, practicability, and convenience, and must be determined by agreement for specific cases. Information is given as to how the interference may be predetermined for given systems so that the merits of the various possible alternatives can be quantitatively compared, while, at the same time, the possibility of interference in connection with a projected system can be found beforehand.

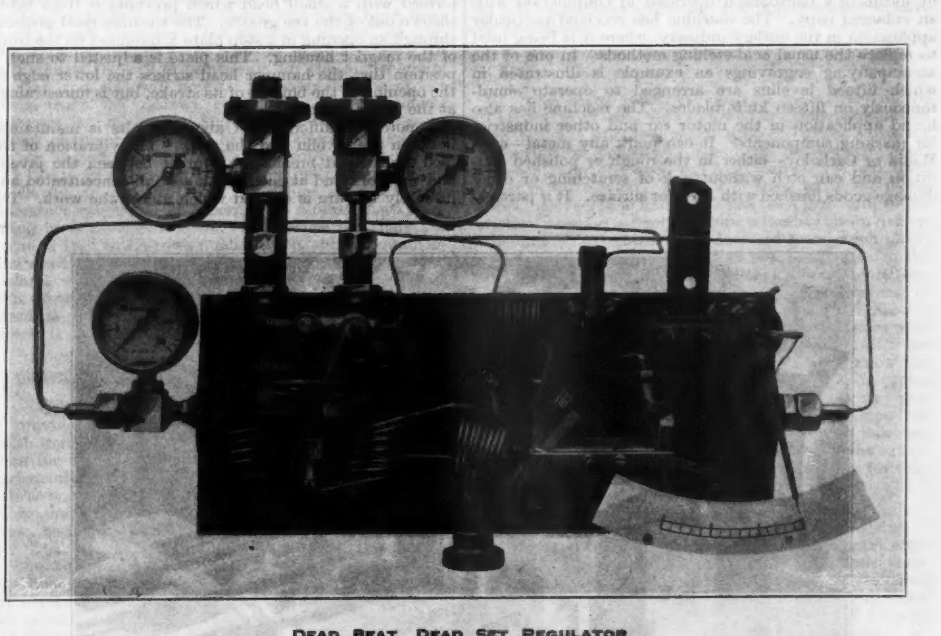
Although further study of certain aspects of the subject is still needed, it is concluded that theory and experience are available for the approximate calculation and predetermination of the amount of interference likely to occur in any given case.

A Dead Beat, Dead Set Regulator.

A new form of regulator for such purposes as controlling the flow through a reducing valve to maintain a constant temperature has recently been devised by the Drayton Regulator and Instrument Company, Limited, of West Drayton, Middlesex, and is illustrated by the accompanying engraving, while its action is indicated in the diagram.

The purpose of this instrument is not merely quickly and positively to adjust the valve with changes of load, but also to assure that the temperature maintained shall be the same at full load, no load, and all intervening stages.

Referring to the diagram, it will be seen that the reducing valve A is actuated by a diaphragm. This diaphragm is subject to an air pressure provided at B at a constant pressure of about 15 lb. per square inch. The air is admitted to a small chamber and passes through a calibrated orifice on its way to A. Beyond this orifice there is a leak away opening C, controlled by the aneroid capsule D. This capsule is in communication with the main air supply, and also with another leak opening E. The extent of this opening E is governed by a radially moving flap F. The movement of this flap is brought about by the attached bell crank F_1 and the thermostat G.



Dead Beat, Dead Set Regulator

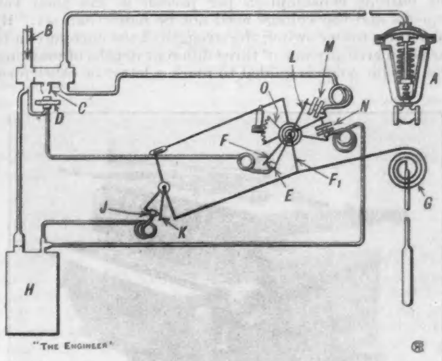
With this arrangement a drop in temperature at the thermostat will cause its coil to wind anti-clockwise, open the gap between F and E, and thus reduce the pressure in the capsule D. This will open the leak away C and reduce the pressure on the diaphragm of the valve A, which will open to pass more steam. The valve takes up its new position almost instantaneously, but at the same time another action takes place.

The orifice E is mounted on an arm that pivots with the arm L which is anchored by the aneroid capsule M. This capsule is in communication with the air pressure for operating the diaphragm of the valve A. The result is that there is a follow-up action between the orifice E and the flap F, which reduces hunting of the valve.

Without other arrangements, however, it is probable that the new position of the valve would be such that the temperature maintained would be slightly above or below the standard required.

In order to meet these conditions there is a further control of the setting, which embodies a time-lag device in the form of an air receiver H. This receiver is supplied with air under pressure through an orifice, and has a leak-away J and flap K. This flap is interconnected with the thermostat G.

The air receiver H is connected with the capsule N, which can move the anchorage of the capsule M. The result is that while a reduction of temperature at G tends to increase the opening E F, and by reducing the air pressure open the valve A, the decrease in pressure in M tends to reclose the opening E F. At the same time the thermostat has closed the opening J K, so that the pressure in H and N is increased and there is a tendency for M and L to move forward and increase the opening E F to reset the valve A. The merit of having a receiver of appreciable capacity at H lies in the fact that it gives opportunity for the conditions to adjust themselves before the resetting takes place. The worm and wheel O provide a means of adjusting the relative positions of the nozzles E and J, and thus setting the instrument.



Action of Regulator

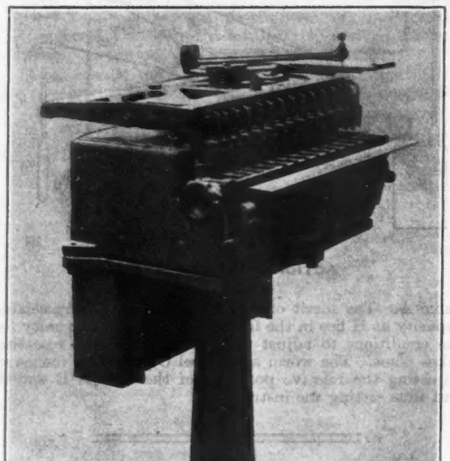
THE MOTOR TRAWLER ALA.

The new motor trawler "Ala," which has recently been constructed at the yard of Richards Ironworks, Ltd., of Lowestoft, for the service of the East Anglian Ice and Cold Storage Company, Ltd., marks a further advance in the use of the oil engine in fishing craft. This new trawler, which has now undergone her official trials, will be the forerunner of a fleet of twelve motor trawlers. She has been designed by Mr. S. G. Richards, and was built under the supervision of Mr. B. S. Tharp, A.M.I. Mech. E., of Hamilton Dock, Lowestoft, the consulting engineer for the owners. She has a length of 75ft., a beam of 20ft. 6in., with an amidship depth of 9ft. 6in., and an after draught of 10ft. Good accommodation is provided for a crew of six men, with a separate cabin for the skipper.

The main propelling motor, which is also arranged to drive the trawl winch by belt, consists of a five-cylinder Ruston and Lister oil engine, designed to develop 150 B.H.P. at 235 r.p.m., the cylinder dimensions being 11in. bore and 14½in. stroke. A simple system of controls has been arranged with compressed air starting, and engine-driven pumps and a 1½ kW, 110-volt generator driven from the main shaft of the engine. The trawl winch was supplied by J. S. Doig and Sons, Ltd., of Grimsby, and it carries 300 fathoms of 2¼in. circumference warp on each drum, two whipping drums being arranged on the high-speed shaft. When the winch is not required, the driving belt is left slack, but the drive is put into operation by means of a jockey pulley operated by the winch man from the deck. An auxiliary unit consists of a 7 B.H.P. single-cylinder Ruston-Lister engine driving a 1½ kW, 110-volt generator, a single-stage air compressor, and a general service pump. The machinery was installed by the Ruston Lister Marine Company, Ltd. The trials of the trawler were, we learn, successful, a speed of about 8½ knots being attained.

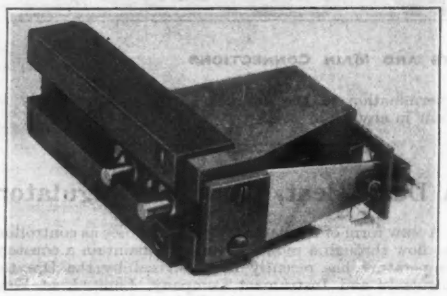
An Electric Etching Machine.

To the considerable range of engraving machines operating with a pointed cutting tool made by Taylor, Taylor and Hobson, Ltd., of Leicester, Mr. Wm. Taylor has now added an engraving or etching machine, in which the pointed cutting tool is replaced by an electric "javelin" from which a rapid succession of sparks passes to the work and so marks it. The javelin is composed of a tungsten alloy and is supplied with alternating current. The current consumption per javelin is less than two ampères and the voltage need not be more than six. By means of a rotary switch the strength of the current can be varied to give any one of three different depths of marking. The javelin point is guided to mark a letter or other form by means of a pantograph operated in conjunction with an enlarged copy. The machine has received particular application in the cutlery industry, where it is being used to replace the usual acid-etching methods. In one of the accompanying engravings an example is illustrated in which fifteen javelins are arranged to operate simultaneously on fifteen knife blades. The machine has also found application in the motor car and other industries for marking components. It can mark any metal—even Widia or Carboloy—either in the rough or polished condition and can etch without risk of scratching or other damage goods finished with a mirror surface. It is particularly suited to operation by unskilled labour. Its total consumption of power is low—the fifteen-unit knife etching machine taking not more than 300 watts—and the current and voltage being of the same order as in a domestic electric bell, there is no danger of the operator's receiving a shock. The javelin points are readily replaced when they become worn and do not need to be re-sharpened during their life.



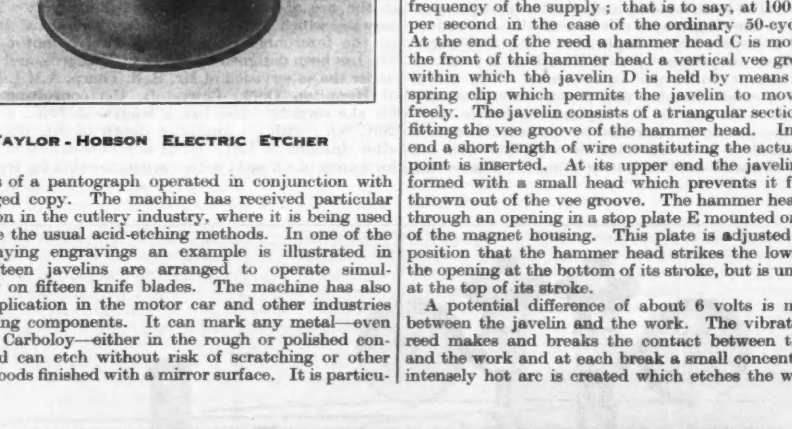
Taylor-Hobson Electric Etcher

The marking units in the knife-etching machine illustrated are bolted to a tee slot running along the front face of a frame mounted on a pair of horizontal pivots. By means of a cam lever this frame can be raised and lowered round these pivots to facilitate the changing of the work. This pivoted frame is mounted outside another frame which is free to move in any direction on a horizontal plane, but is restrained against rotation so as to ensure that all the marking units shall execute the same geometrical movement. The support and constraint of the inner frame are derived from balls rolling in vee grooves, spring loading being applied to eliminate any play that might be produced by wear. The motion of the inner frame and therefore of the marking points is governed by a pantograph of 7 to 1 ratio, the tracing point of which is moved by hand round the raised or sunk edges of a pattern fixed to a copy-holding table attached to the side of the machine. The pantograph joints are fitted with ball bearings with provision for taking up wear. In certain of the joints self-aligning bearings are provided with the object of avoiding any straining of the pantograph members produced as a result of the fixed and moving axes not being exactly parallel. Despite the fairly heavy weight of the moving parts, these arrangements impart great sensitiveness and sweetness of movement to the machine.



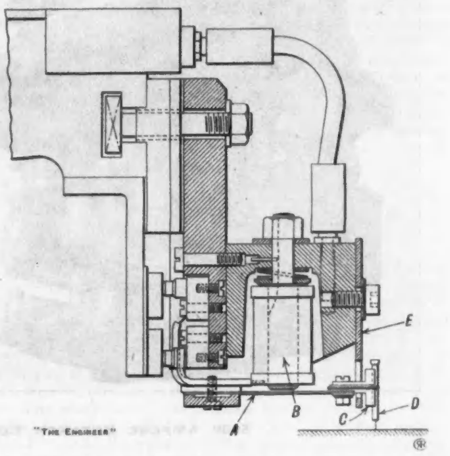
An Etching Unit

The marking units can be spaced along the tee slot in the frame supporting them at intervals to suit the width of the work being dealt with. Each is complete in itself. A stiff steel reed A is mounted beneath an alternating current magnet B and is tuned to vibrate at twice the frequency of the supply; that is to say, at 100 vibrations per second in the case of the ordinary 50-cycle supply. At the end of the reed a hammer head C is mounted. In the front of this hammer head a vertical vee groove is cut within which the javelin D is held by means of a light spring clip which permits the javelin to move endwise freely. The javelin consists of a triangular sectioned shank fitting the vee groove of the hammer head. In the lower end a short length of wire constituting the actual working point is inserted. At its upper end the javelin shank is formed with a small head which prevents it from being thrown out of the vee groove. The hammer head projects through an opening in a stop plate E mounted on the front of the magnet housing. This plate is adjusted to such a position that the hammer head strikes the lower edge of the opening at the bottom of its stroke, but is unrestrained at the top of its stroke.



Etching a Batch of Table Knives

A potential difference of about 6 volts is maintained between the javelin and the work. The vibration of the reed makes and breaks the contact between the javelin and the work and at each break a small concentrated and intensely hot arc is created which etches the work. The arrangement is self-feeding. When the hammer head strikes the lower edge of the aperture through which it projects the sudden check to its motion causes the lightly held javelin to shoot downwards in its groove until its point makes contact with the work surface. In this way compensation is provided for the burning away of the javelin point, which occurs in course of time. In addition, this automatic adjustment of the javelin point enables etching to be done as readily on a curved as on a flat surface. The depth of the etch is, as previously stated, controlled by the voltage applied. The width of the etched lines is governed by the diameter of the javelin point. As the point burns away its diameter remains constant and therefore no change occurs in the width of the etched lines. The life of the javelin depends upon the depth of the marking. On such work as stainless cutlery with inscriptions of a usual character about twenty gross of knives, we are informed, can be marked with one set of fifteen javelins. The total power consumption of the knife-etching machine is about 300 watts. Its output is at the rate of from ten to twelve letters per minute marked simultaneously on the fifteen articles. The units can be provided separately for use in any ordinary engraving machine in place of the cutting tool. In one form the unit is supplied as a hand instrument, whereby freehand etching without a copy can be performed.



Details of Etching Unit

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Mr. L. I. C. Schwaiger, who was associated with the export department of Blackstone and Co., Ltd., has now joined Davey, Paxman and Co. (Colchester), Ltd., as manager of the overseas department.

Marshall, Sons and Co., Ltd., Gainsborough, inform us that they have recently appointed Harry Astbury, Ltd., of 63, Hockley Hill, Birmingham, as their representatives in the Birmingham district.

Hick, Hargreaves and Co., Ltd., Soho Ironworks, Bolton, have sent us a copy of an attractive brochure which they have issued in connection with their centenary, which was referred to at some length in our issue of November 10th, 1933.

We understand that the business of Sir John H. Biles and Co., naval architects, is being carried on by the late Sir John Biles' former colleagues, without alteration of name, and that the firm has received re-appointment as naval architects to the Government of India.

The Associated Equipment Company, Ltd., has appointed Mr. C. W. Reeve, the present managing director of the company, to be chairman of the board, and also to continue in the office of managing director. Lieut.-Col. J. T. C. Moore-Brabazon, M.C., at the same meeting, was elected to be deputy chairman.

Cox and Danks, Ltd., Stevenson-road, Sheffield, 9, request us to say that their activities on the North-East Coast as iron and steel merchants will be conducted through a new branch office, which will be opened at Prudential Buildings, Mosley-street, Newcastle-on-Tyne (telephone number 27900), on December 4th, with Mr. J. Farrer as manager.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

Stewarts and Lloyds, Ltd., have received from the Crown Agents for the Colonies a contract to supply the steel portion of the pipe line required for supplying water to Jerusalem. The order consists of about 31 miles of 18in. steel pipes, which are to be used for pumping water from the springs at Ras-el-Ain. There will be four pumping stations with a reservoir at each. The mains will follow the railway to Lludd and thence the road from Jaffa to Jerusalem. The scheme is to be proceeded with immediately and it is understood that the construction is in the hands of the Public Works Department under the direction of Mr. Fawcett Pudsey, Director of Public Works, Palestine.

LAUNCHES AND TRIAL TRIPS.

Great Western, twin-screw steamer; built by Cammell Laird and Co., Ltd., to the order of Great Western Railway Company, for Fishguard-Wexford service; dimensions, 280ft. by 40ft. 3in. by 17ft. 1in.; to carry passengers and cattle. Engines, triple-expansion; constructed by the builders; launch, November 21st.

Inchangu, motor vessel; built by Workman, Clark (1928), Ltd., to the order of Messrs. Andrew Weir and Co., London; dimensions, 425ft. by 57ft. by 37ft.; to carry passengers and cargo. Oil engines, Workman Clark-Sulzer type; constructed by the builders; launch, November 21st.

Engineers' German Circle.—On the evening of Monday, November 27th, members, friends of the Circle and their ladies met at the Holborn Restaurant for a dinner and dance. Over forty members and guests were present, and the chair was taken by Dr. S. J. Davies. Herr E. H. Rüter, of the German Embassy, proposed the toast of "The Ladies," and paid a tribute to the good work the Circle is doing in bringing together the engineers of the two countries on the basis of their work. A very enjoyable evening was spent, and thanks are due to Mr. H. P. Spratt, the secretary, for the excellent arrangements made. Any inquiries as to the membership and activities of the Circle should be addressed to Mr. Spratt at the Science Museum, London, S.W.7.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Forthcoming B.S.I. Specifications.

Two interesting specifications are likely to be issued shortly by the British Standards Institution. For some time the Institution has been dealing with the new specification for high-tensile steel, and this has now been practically approved and will be published probably before Christmas. It is understood that the new tensile stress will be 37/43 tons and that the yield point will be 23 tons. The interest attaching to this specification arises from the growing demand for this class of steel. Other countries are taking up its manufacture in increasing quantities. The German steel makers in particular are developing this side of their business, and it is stated that recently 50 per cent. of their steel exports have been of special steel. In France, too, there is a tendency to concentrate upon the output of high-tensile material. Another specification which is awaited with interest relates to wrought iron bars. Specification 51 has been revised and in the course of revision further special grades of puddled iron bars which are used in the manufacture of chains and lifting material have been included,. It is probable that this specification will be circulated for comment shortly.

Pig Iron.

The chief characteristic of this market is the willingness of consumers and dealers to place forward contracts, and the caution with which many of the producers negotiate this class of business. The position varies in different parts of the country, but, excepting perhaps in Scotland, there is a similarity in the general features of the market, which all tend towards firmer conditions. The position of foundry iron on the North-East Coast is causing some anxiety to users, and this is indicated by the pressure which is exercised upon makers to enter into long-date delivery arrangements. In some cases business has been done for delivery as far forward as the end of June next year. There seems no doubt that the whole of the foundry iron produced on the North-East Coast is going into consumption, the greater part of it being taken up by local and Scottish consumers. In the latter market Northamptonshire brands are being offered at 64s. d/d Glasgow and 61s. d/d Falkirk, against the 65s. 3d. and 62s. 3d. quoted by the Cleveland makers, but most of the light casting foundries are so accustomed to Cleveland iron that they take larger quantities of that description than of Northants. Stocks in the Midland makers' hands still amount to a substantial tonnage; but taking into account the iron sold for forward delivery plus the quantities disposed of in day-to-day sales, heavy inroads have been made in these accumulations. In this district, however, consumers appear to entertain little fear of a shortage arising for some time, and some are content to keep themselves covered only a short distance ahead. In Lancashire buying has been more satisfactory than for some time, consumers in this district apparently being somewhat apprehensive of an advance in prices. It is not easy to judge the position in the basic iron market, as so much of the business transacted in this description does not come on the open market, owing to the steel works taking it from associated concerns. So far as can be judged, little business has been done since prices were increased, a number of large contracts having been entered into immediately before the advance. There is also a steady sale of Indian basic, which is imported by arrangement with the Indian producers at the rate of 60,000 tons per annum. It is said that the British makers would like this quantity reduced, but the arrangement is not likely to be varied for some time. Business in hematite iron is satisfactory, and some makers have declined to sell far forward at current rates.

The N.E. Coast and the Midlands.

There is no sign so far of the falling off in business which usually occurs a few weeks before Christmas in the finished steel department of the market. The demand for nearly all classes of these products is growing, but the outstanding feature of the position is the heavy pressure on the part of merchants and consumers to secure supplies of small steel bars. The steel works and the re-rollers alike are full up with orders, and in many cases are behindhand in deliveries. On the North-East Coast business has expanded so much that it is expected the two steel furnaces which have been relighted will have to be increased to four. The constructional steel shops in this district are better employed than in other parts of the country, but would welcome new business. The rail mills are also busy on recent orders. The active conditions which have ruled in the Midlands for some time show no sign of relaxing. The demand for structural steel arising from the engineering industries has improved, but the number of large engineering orders coming to this district is limited by the competition experienced from outside, particularly from the North-East Coast. The lighter branches of the trade, however, are probably busier in the Black Country than elsewhere. Continental competition is strong in small bars, strip, joists and structural steel generally, but in spite of the comparatively low prices accepted by foreign sellers, the bulk of the business passing is going to British works. The situation as regards strip is particularly satisfactory, and many of the makers are rationing their customers and in some cases are behindhand in deliveries. For small bars the re-rollers quote £7 5s., whilst the steel works ask £7 10s. to £8 10s., according to quality. The Continental steel works organisations are willing sellers at £6 10s. to £6 10s. 6d. d/d, including duty. Stockholders, however, do not seem to be placing much business with Continental works, perhaps because there is a marked tendency on the part of users to require British material. Another department of the industry which has shared in the recent improvement in business is that providing colliery material. The demand, however, is restricted to small tonnages, and buyers are limiting their requirements as much as possible.

Scotland, Lancashire, and the North.

The better outlook in the shipbuilding industry has created a cheerful feeling in the Scottish steel industry. The total tonnage of steel which will be required to complete the orders may be only moderate, judging from the quantity which finds an outlet in the shipyards in normal times, but the new orders are believed to be only the beginning of renewed activity on the Clyde. For longer than most of the steelmakers care to remember, the poor demand for the descriptions of steel used in shipbuilding has been reflected in idle plant at the steel works, and the prospect of an improvement in this direction has improved the tone of the market. The announcement that a share of the order for a hundred locomotive engines for the L.M.S. Railway will be allocated to a Glasgow firm is welcome news for the plate mills, since business in boiler plates in particular has been at a low ebb for some time. The reverse side of the picture, however, is presented by the re-rollers, who are sharing in the trade improvement to only a moderate extent. Short time working is general in this department, and little improvement is to be seen in either the home or export demand. There has been an active request for sheets of late, and this section of the industry is assured of busy conditions until the end of the year. In Lancashire the orders for locomotives already referred to will provide a stimulus to the plate industry for which it has been waiting for some time. Officially, the quotation for boiler plates is £8 5s., but lately makers have not rigidly adhered to this limit when a good order was in prospect, but these have been few and far between. The quantities of steel required by the constructional engineering establishments is showing some improvement, but is still well below the capacity of the steel works. There is a strong demand for bright drawn steel and for black steel bars, and the re-rollers are so busy on the production of small steel bars that they are cautious in committing themselves to forward contracts. Continental merchant bars and structural material have been freely quoted in this market, but the business passing with either merchants or consumers has been confined to small quantities. No special feature has developed in the Sheffield market, but the rate of operations at the steel works has been maintained.

Finished Iron.

Business in the finished iron department continues to hang fire, although the orders for railway wagons and locomotives will bring a welcome increase in work, particularly to those firms supplying the better-class descriptions. Recently, also, some orders from the Indian railways have reached the industry, but these have been for only small tonnages. The situation at the bar iron mills seems to be much the same in most districts. In the Midlands the call is principally for the higher grade material, and this will now be increased by the orders arising from the railway contracts. The commoner grades are less in demand and continue to feel the competition of the cheaper steel bars. Staffordshire marked bars are quoted at £12 at works; Crown bars are quoted at £8 10s. to £9 10s., and the common quality ranges from £6 17s. 6d. to £7 10s. The Lancashire mills are only moderately employed, but there is no indication of price cutting on a noticeable scale. Lancashire best bars are firm at £9 10s., with Crown quality at £9, cheaper qualities being quoted down to £7. Similar conditions prevail in Scotland, where the plant at most works is occupied only about three days a week. Scottish Crown bar iron is offered at £9 15s., d/d railway sidings, whilst export business is conducted on the basis of £9 5s. f.o.b.

Current Business.

The 1934 programmes of the railway companies are providing a considerable volume of work for the British iron and steel makers. The L.M.S. has given out orders for 100 railway locomotives, this contract being supplementary to that for 2000 wagons recently placed. Of these engines, fifty will be built by the Vulcan Foundry and Engineering Company, Ltd., of Newton-le-Willows, Lancs., and fifty by the North British Locomotive Company, Ltd., of Springburn, Glasgow. Several new orders for ships have been placed, including one for a 10,000-ton cargo boat with Wm. Hamilton and Co. (1928), Ltd., of Port Glasgow, whilst Harland and Wolff, Ltd., of Govan, have taken a contract for a refrigerated cargo motor ship of 12,000 tons d.w. and a 12,000 tons d.w. oil tanker. A contract which will provide welcome employment for the tube works has been secured by Stewarts and Lloyds, Ltd., for the supply of the pipe line for the Jerusalem water supply scheme. This line will consist of about 31 miles of 18in. steel pipe. There will be four pumping stations with a reservoir at each station, and the orders for the pumping machinery will also be placed with British works. The Trinidad water supply scheme, which has been held up for a time, is likely to be proceeded with, and this may provide work for the British tube makers. This scheme may be spread over a number of years. It is also announced that the old Brymbo Steel Works, near Wrexham, are to be reopened after being closed down for three years. The Crown Agents for the Colonies have awarded the Motherwell Bridge and Engineering Company, Ltd., Lanarkshire, the contract for a road and rail bridge in Jamaica, and for a road bridge in Kenya. The same firm has taken a contract for the erection of a road bridge in Natal. Ashmore, Benson, Pease and Co., Ltd., of Parkfield Works, Stockton-on-Tees, have secured an order for the construction of a blast-furnace at the Cardiff Steel Works of the British (Guest, Keen and Baldwins) Iron and Steel Company, Ltd. The furnace will be capable of a weekly output of 4000 tons of pig iron, and will probably be completed by about the middle of next year. Balance sheets of some of the electrical engineering concerns point to sound conditions in that industry. Crompton Parkinson, Ltd., show a profit of £102,187 for the year ending September 30th, 1933, and the following dividends are recommended:—4 per cent. on the 8 per cent. first preference shares, and 3 per cent. on the 6 per cent. second preference shares in respect of the six months ended September 30th, 1933; 6½ per cent. actual on the ordinary and "A" ordinary shares, making, with the interim dividend paid in June, 12½ per cent. for the year. The British Electric Transformer Company, Ltd., shows a profit of £18,463, against a loss last year of £10,265. A dividend of 5 per cent. on the preference shares for the nine months ending September 30th, 1933, is recommended.

Copper.

Rather steadier conditions have ruled in the electrolytic copper market this week, although buying has been on anything but an important scale. The copper producers have taken advantage of the firmer tone of the dollar to raise their prices slightly, and their export quotation, after being unaltered for some days at £33 10s., advanced to £33 15s. The worst feature of the market is that consumers have not shown much interest in the metal. In America conversations are being continued regarding the copper "code," and it is expected that it will soon be put into operation. The general view is that it will provide for a domestic consumption in the United States of about 20,000 tons to 22,000 tons per month. Possibly, this will about meet the demands of the market, but it is far below the normal consumption, which even before the war was about 30,000 tons per month. The producers point to the steady reduction in the stocks which has taken place during the last few months. At the end of October the stocks in North and South America were given as 520,500 tons, whilst the production was only 33,500 tons. Some doubt, however, is felt regarding these figures, as it is suggested that earlier in the year large copper-using concerns which are associated with producing interests took important quantities of the metal in order to relieve the latter from some of the burden of carrying the metal. It is assumed that all this copper has not been used, and that in considering the copper position in America allowance must be made for these hidden stocks. The London standard market, after showing a certain amount of weakness, became suddenly active at the beginning of this week on a considerable volume of speculative buying and bear covering. Prices advanced rather sharply, but there seemed little confidence in the market, and it would not be surprising if a reaction took place. Buying for investment purposes in this market seems to have ceased for the time being, and, in fact, a fair proportion of the purchases made early in the year appear to have been liquidated.

Tin.

An easier tone developed in the market at the end of last week, and was followed by some liquidation which brought about a sharp drop in prices. Buying by Continental consumers has been particularly poor, and excepting at the week-end American buyers took little interest in the market. In spite of these adverse circumstances, however, the undertone has been firm, and as the statistical position is likely to show a further improvement at the end of November there does not seem much likelihood of an important decline in values. Deliveries in the United States are not expected to reach a large figure, but on the other hand, there have been heavy shipments of tin to Russia this month, which have helped to swell deliveries to the Continent. Some of the recent sales were ascribed to operations by interests associated with the Pool, and the market would very much like to know the extent of the holdings of that body. Business in tin-plates has declined somewhat of late, both in this country and in America, and this, of course, may reflect upon the demand for tin. The worst feature of the market has been the indifference shown by consumers and to a great extent the fluctuations of the dollar exchange are blamed for this.

Lead and Spelter.

A steady tone has ruled in the lead market after prices had shown a weaker tendency. Of late there has been a considerable amount of liquidation of stale bull accounts, but in some cases the market is inclined to think that metal which was bought some time ago as a hedge against currency depreciation has been disposed of. Recently the Soviet Government bought important quantities and most of the Mexican lead which was declared on market early in November has thus been disposed of. The industrial demand has been fair, but most of the large consumers appear to be well covered. The favourable weather, by enabling building operations to be continued late into the season, has helped to maintain the demand for manufactured products, and this is reflected in a sustained if small demand for pig lead. . . . The position in the spelter market has not materially altered, prices have been firm, although there has been a certain amount of liquidation of speculative accounts. The statistics issued by the Continental Cartel showed an increase in the stocks of about 1500 tons, whilst the October production is given as 57,877 tons. The demand from consumers has been upon a disappointing scale, the requirements of the galvanisers in particular being less than normal at this season. On the Continent, however, it is reported that industrial requirements, after declining for some time, have again increased. A peculiar position has arisen in the market for re-melted spelter. The quantities produced in this country are not sufficient to meet requirements, and as imported metal is subject to a duty, prices have advanced to £16 5s. to £17.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

FUEL OIL.

Inland consumption; contracts in bulk.
Exclusive of Government tax of 1d. per gallon.

Ex Ocean Installation.	Per gallon.
Furnace Oil (0·950 gravity)	3½d.
Diesel Oil	4d.

Manchester prices ¼d. per gallon extra.

French Engineering Notes.

(From our own Correspondent in Paris.)

French Trade Policy.

THE policy of trade restrictions and reprisals which has seriously disturbed foreign commercial relations during the past few years has had the effect of reducing this country's exports to about two-fifths of what they were four years ago. The fall in the monthly returns is continuous and threatens to reach a level at which exports will count little as a factor in the country's economic prosperity. Attempts to "adjust" the conditions of production costs abroad to those existing here, by means of expedients such as the compensating tax and turnover tax on goods imported, and incidentally to raise more money for the Treasury, have had no other effect than to close up the channels to French trade. Successive Governments have endeavoured in their different ways to give satisfaction to conflicting industrial and commercial interests, and have only succeeded in eliminating exporting industries without providing activity to the home trade. The decision of the British Government to impose an additional duty of 21 per cent. on certain imports from France so long as this country maintains the compensating tax of 15 per cent. and the turnover tax of 6 per cent. has brought matters to a head, and will necessitate the withdrawal of the French from an impossible situation or will, in the words of one authority, "strike a death-blow at French trade with Great Britain." The situation has been rendered impossible by the insistence with which the French claimed commercial concessions in return for a suppression of the compensating tax. The idea of this compensation has been general, even amongst exporters who are suffering from its effects upon trade with Great Britain, and a final attempt to obtain concessions was to have been made by the late Minister of Commerce, Monsieur Laurent Eynac, who had, nevertheless, to cancel his proposed visit to Mr. Runciman as the result of a diplomatic intimation that any discussion on this subject was undesirable. The British ultimatum arrived at a time of political crisis, and nothing can be done until the new Government gets to work; but in view of the seriousness of the situation, from the point of view of exporting industries, it is not improbable that the prospect of an exclusion of French products from Great Britain will modify the future trade policy of this country.

Compagnie Generale Transatlantique.

With the appointment last week of the board of directors, the Compagnie Générale Transatlantique was definitely constituted on new lines, which give to the State a majority of voting power with ten members, while shareholders have appointed six members to represent them, and there remain two others to be elected respectively by the office staff and the officers and seamen. The company has, in fact, become a State organisation, with the collaboration of shareholders and workers, who can obviously take no effective part in the decisions arrived at by the majority. The State control was imposed on account of the considerable financial assistance it had rendered in order to prevent the company from foundering, and also because the necessity of paying subsidies gave a claim to the State to see that the company is properly administered. Of the directors representing the State, four are financial experts. The State has therefore taken upon itself a responsibility for the Compagnie Générale Transatlantique which will, no doubt, be regarded by investors as offering a guarantee when the new share issue is made. Nevertheless, its control of a commercial enterprise does not meet with general approval. It is accepted because, without State intervention, the Compagnie Générale Transatlantique would infallibly have gone into liquidation.

Import Licences.

The system under which import licences are granted has already given rise to considerable trouble, particularly for coal, and it will become an absurdity if the Government carries out its proposal to put licences up to auction with the object of raising funds for the payment of subsidies to farmers. The latitude allowed to responsible groups in different countries to distribute licences allotted to them will, according to the proposed arrangement, be withdrawn, and the French Department of Commerce will itself grant licences to the highest bidders amongst a selected list of importers. The immediate result of this system will inevitably be to create monopolies and to increase prices to consumers. Opposition to the scheme is so general that it is doubtful whether the Government will persist in a plan which, it is said, is bad in itself and may provoke reprisals from other countries. The reduction of the import quota for coal by 10 per cent. is also severely criticised. Consumers object to pay more for coal in order to keep a very small proportion of the working population in employment, and it is suggested that the far greater class of operatives in ironworks, factories, and shops which must have cheap coal, as well as dockers and others interested, should combine and agitate as strenuously for the abolition of the import quotas as the miners do to maintain them.

The Steel Cartel.

At a meeting of the Steel Cartel in Paris last week the difficulties that threatened the withdrawal of the Forges de Clabecq at the end of the year were removed by the Belgian "Cosibel" group making concessions to Clabecq, which is understood to have agreed to continue its association with the International Steel Union. The firm was offered the greater part of an order for sheets from Russia. This incident indicates an element of weakness in the situation of the Cartel, in view of the fact that a sheet rolling firm like Clabecq was deprived of its special competitive advantages. Another matter that may affect indirectly the Cartel is the possibility of an understanding between German and Polish steel makers, who are reported to be endeavouring to find a basis for collaboration, particularly in the way of giving more vitality to the steel industry in what was formerly Upper Silesia. Poland has refused to adhere to the Steel Cartel on the ground that it was not satisfied with the quota offered.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

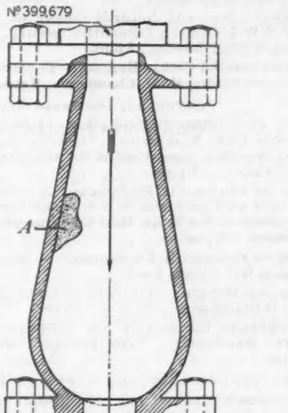
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

INTERNAL COMBUSTION ENGINES.

399,679. December 16th, 1932.—DEVICES FOR PREPARING FUEL-AIR MIXTURES FOR INTERNAL COMBUSTION ENGINES, D. N. Hapkins, 109, South Carondelet-street, Los Angeles, California.

This mixer is intended to be arranged between the carburettor and the inlet manifold, and depends for its action on the changes in velocity and pressure caused by passing the gases through a divergent-convergent passage. As shown, the passage starts with a conical form and ends as a hemisphere. It is recommended that the length of the conical part should be 77 per cent., and the radius of the hemisphere 23 per cent. of the total length. It is also suggested that the interior surface should be roughened as shown at A.—*October 12th*, 1933.

No 399,679

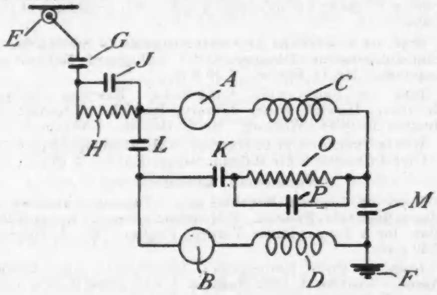


DYNAMOS AND MOTORS.

399,832. April 4th, 1932.—SYSTEMS FOR CONTROLLING ELECTRIC MOTORS, William Train Gray, of "Darroch," Wainwright-road, Altrincham, Chester, and Associated Electrical Industries, Ltd., of Crown House, Aldwych, in the City of Westminster.

A system is described in this specification for controlling electric motors and has for its object to provide improved arrangements whereby compound wound direct current motors can be connected in series or in parallel, the transition from series to parallel connection being effected by what is commonly known as the short circuit method. The motor armatures are indicated at A, B, and their respective series field magnet windings at C, D. The positive terminal of the supply is indicated at E, and earth at F. G is the line switch. H is an accelerating or decelerating resistance provided with the usual short-circuiting switch J, so that it can be included in the circuit of the motors, whether they are in series or parallel. The "series" switch by which the two motors are connected together in series when the circuit is closed is indicated at K, and L and M are the switches by which the motors are connected in parallel, L being called the "parallel" switch and M the "earth" switch. The shunt field magnet windings for the motors are not shown. The transition resistance O is included in series with the series switch K, and is provided with a short-circuiting switch P. In effecting the transition from series connection of the motors to parallel connection the sequence of operations is as follows. In the full series connection of the motors switches G, J, P and K are closed, and the circuit is from the supply E, switch G, switch J, armature A, field winding C, switch P, switch K, armature B, field winding D, and earth F. To change to parallel operation switches J and P are opened and the parallel switch L and the switch M are closed, thereby connecting the motors in parallel and shunting them directly by the resistance O. The series switch K is then opened so as to break the circuit through the resistance and leave the motors connected in parallel. Switch J can then be closed so as to short circuit the resistance H if desired. In changing the connections of the motors from parallel to series the sequence of operations above described will be carried out in the reverse order.—*October 4th*, 1933.

No 399,832

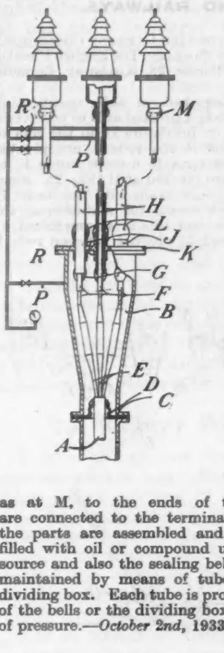


TRANSMISSION OF POWER.

399,215. April 1st, 1932.—TERMINAL DEVICES FOR ELECTRIC CABLE SYSTEMS, Siemens Brothers and Co., Ltd., of Caxton House, Tothill-street, Westminster, London, S.W.1; and Henry Gurney Wood, of "Kinross," Leesons-hill, Chislehurst, Kent.

In some high-tension systems the cable is subjected to pressure exerted by a pressure medium, *e.g.*, gas, in the cable duct or the interior of the cable is under pressure, such as in the oil-filled system. In both cases the cable accessories must be connected to a source of pressure and conveniently oil under pressure is used as the pressure medium. In an ordinary electric cable system a multi-core cable, when it is to be terminated, is generally introduced into a dividing box which is provided with insulated terminals. Where, however, the dividing box contains a medium such as oil under pressure other considerations arise. One feature of the invention is that the several cores of a multi-core cable are terminated in separated end sealing devices and provides an improved arrangement whereby operations can be carried out on any one of the sealing devices without the others being affected, the sealing ends being connected to the cable through a dividing box closed by being connected to the cable at one end and to single-core tail pieces at the other end. The cable A is led into a dividing box B through a diaphragm C, which may itself incorporate or may have attached to it a flexible coupling D which takes up strains to which the lead sheathing of the cable is subject. In the dividing box the cable cores E open out and the individual cores are jointed to tail pieces F of lead-sheathed cable. Plumbed to the tail pieces, as at G, are pipes of copper or other non-ferrous metal, which pass through sleeve-like bosses J on the cover K of the dividing box. The ends of the pipes H which are outside the dividing box are plumbed, as at L, to the bosses. The sealing bells are plumbed, as at M, to the ends of the pipes and the tail pieces are connected to the terminals mounted on the bells. When the parts are assembled and closed the dividing box B is filled with oil or compound under pressure from an external source and also the sealing bells, the pressure being separately maintained by means of tubes P for each of the bells and dividing box. Each tube is provided with a valve R so that any of the bells or the dividing box can be isolated from the source of pressure.—*October 2nd*, 1933.

No 399,215

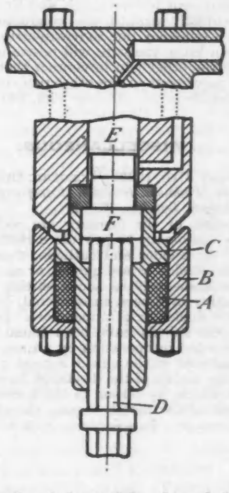


MACHINE TOOLS AND SHOP APPLIANCES.

399,773. September 12th, 1932.—PNEUMATIC HAMMERS, F. Hills, 45, Airthrie-road, Goodmayes, Ilford, Essex.

This is a rubber buffer to prevent damage to the hammer in the event of the tool not being held up to its work. The rubber buffer is shown at A and is held in the cap B, which is secured to the body of the tool by through bolts. The tool chuck C is provided with a flange which bears on the top of the buffer. In the absence of the resistance of the tool D, the hammer E drives the anvil F against the chuck and the blow is taken up by the buffer.—*October 12th*, 1933.

No 399,773



FURNACES.

400,020. December 19th, 1932.—ELECTRIC FURNACES, Société Anonyme des Manufactures des Glaces et Produits Chimiques de St. Gobain, Chauny and Cirey, of 1bis, Place des Saussaies, Paris.

The electric furnace described in this specification is for fusing metals of high melting point. In Figs. 1 and 2 the resistor is constituted by a straight rod A of carbon or graphite, the ends of which are supported in sleeves B carried by movable plates C,

No 400,020

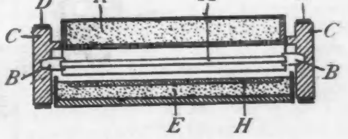


Fig. 1

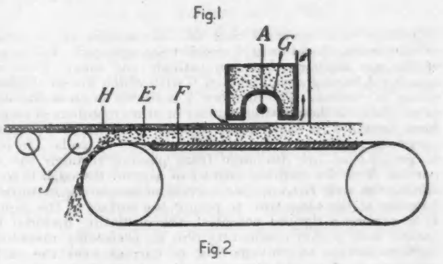

Fig. 2

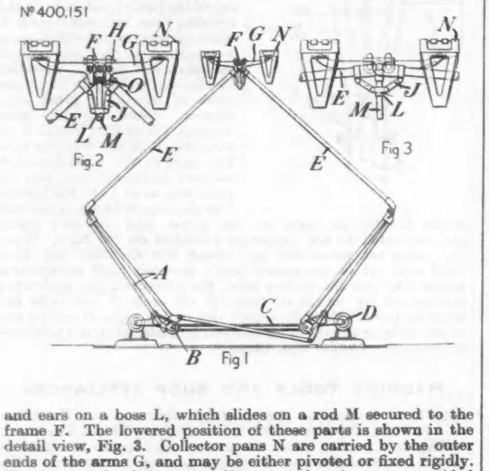
also of carbon. These plates are fixed in metal frames D, which are connected to the terminals of a current source. The primary material E to be fused is distributed in a pulverulent state on a conveyor F, which causes it to pass below the heating apparatus constituted by the resistor A and the chamber G at a speed of displacement regulated so as to fuse a predetermined thickness of the material. The plate H thus fused travels on rollers J, while the pulverulent bed remaining unfused is removed at the end of the horizontal course of the conveyor. The material shown at K is heat insulation.—*October* 19*th*, 1933.

TRAMWAYS AND RAILWAYS.

400,151. July 17th, 1933.—PANTOGRAPH CURRENT COLLECTORS FOR ELECTRIC RAILWAYS AND THE LIKE, The English Electric Company, Ltd., of Queen's House, 28, Kingsway, London, W.C.2.

The pantograph (Fig. 1) described in this specification comprises a framework of lower rods A pivoted at B to transverse axes on a framework C carried on insulators D on the roof of the vehicle. To the upper ends of the rods A are pivoted rods E pivoted together at their apex to a cross frame F, to which the pan-carrying arms G are pivoted at H (Fig. 2). Since the arms G do not form a rigid connection with the frame F, it is necessary to provide other means for maintaining the frame in position about its axis, and this is accomplished by means of the links J (Figs. 2 and 3) pivoted between rods E and ears on a boss L, which slides on a rod M secured to the frame F. The lowered position of these parts is shown in the detail view, Fig. 3. Collector pans N are carried by the outer ends of the arms G, and may be either pivoted or fixed rigidly. The inner ends of the arms adjacent to the pivots are provided with right-angled extensions O, Fig. 2, between which there is a spring tending to force the projections O apart, the one acting as the abutment for the other, and thus tending to hold each pan individually against the conductor wire. In this manner, whilst a tendency due to irregularity in the conductor to make one pan leave the wire will create a greater pressure tending to hold the other pan in contact therewith, it will not give a positive movement to the other pan equal to that of the pan which leaves the wire.—*October* 19*th*, 1933.

Nº400,151



MISCELLANEOUS.

399,498. February 27th, 1932.—ELECTRIC DISCHARGE DEVICES, *The British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2.*

In the operation of the mercury arc rectifier and similar apparatus, it is customary to provide metallic members interposed between the anodes and cathode, these members functioning as anode shields or arc guides, or as control electrodes or grids, or simultaneously as anode shields and control electrodes. Difficulties have been encountered, however, in the use of these metallic shields or grid members. In many instances, for example, steel shields have been found to be perforated and heavily corroded in operation by an arc discharge passing through the material of the shield instead of around its edge to the anode, this action of the discharge forming on the shield a cathode spot which, by reason of the condensation upon the associated anode of the metal, vapour thereby formed caused arc back of this anode. In accordance with the invention, these difficulties are overcome and the advantages of a metallic or conducting shield or grid member are retained. In the path of the arc discharge between cathode and anode there is a member A having a wall portion B with which the arc discharge comes in contact. The member A is shown as an anode shield or arc guide, although this member or other members of suitable form mounted in any suitable manner may be used for other purposes, particularly as control electrodes or grids. In order to prevent an arc discharge from passing through the wall portion B of the member instead of around the edge C to the anode, the wall B comprises a body of insulating material D. In order at the same time to permit the surface of the member B to assume a desired potential, the insulating material D is coated with a thin conducting film E, preferably metallic, of high resistivity to prevent flow of current over the surface sufficient to cause the formation of cathode spots.—*September* 27*th*, 1933.

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

To-day.

INST. OF MECHANICAL ENGINEERS.—Storey's-gate, S.W.1. Thomas Lowe Gray Lecture, "High-speed Diesel Engines for Marine Service," Mr. H. R. Ricardo, F.R.S. 6 p.m.

INST. OF MECHANICAL ENGINEERS: GRADUATES.—Carr's Restaurant, Strand, W.C.2. Smoking concert.

INST. OF SANITARY ENGINEERS.—At Abercorn Rooms, Great Eastern Hotel, Liverpool-street, E.C.2. Annual dinner. 6.45 p.m.

JUNIOR INST. OF ENGINEERS.—39, Victoria-street, S.W.1. "Dairy Machinery and Plant," Mr. W. Chopping. 7.30 p.m.

N.E. COAST INST. OF ENGINEERS AND SHIPBUILDERS.—In Mining Inst., Newcastle-upon-Tyne. "The Electric Welded Ship 'Peter G. Campbell,'" Mr. N. M. Hunter. 6.p.m.

PHYSICAL SOC.—At Imperial College of Science and Technology, S.W.7. Editing Committee meeting, 3.30 p.m.; Council meeting, 4 p.m.; meeting, 5 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. —Discourse by Mr. R. M. Chambers. 9 p.m.

SATURDAY, DECEMBER 2ND.

INST. OF BRITISH FOUNDRYMEN: LANCASHIRE BRANCH.—Engineers' Club, Manchester. "Unorthodox Methods of Commercial Moulding Sand Control for the Modern Ironfounder," Mr. F. Hudson. 4 p.m.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN STUDENTS.—Joint visit with graduates of N.E. Coast Inst. of Engineers and Shipbuilders to the Pelaw Main Collieries coal-washing plant at Wrekenton. 3 p.m.

INST. OF ELECTRICAL ENGINEERS: N. MIDLAND STUDENTS.—Visit to B.B.C. House, Leeds.

INST. OF METALS: BIRMINGHAM LOCAL SECTION.—Midland Hotel, Birmingham. Dinner and dance. 7 p.m.

STEPHENSON LOCOMOTIVE SOC. (MIDLANDS).—At Crumpsall Library, Manchester. "The Liverpool Overhead Railway. 6.30 p.m.

MONDAY, DECEMBER 4TH, TO FRIDAY, DECEMBER 8TH.

SMITHFIELD CLUB SHOW.—At Royal Agricultural Hall, Islington, N.1. 9 a.m. daily.

MONDAY, DECEMBER 4TH.

CHARTERED SURVEYORS' INST.—12, Great George-street, S.W.1. "The Law Relating to Electricity Supply," Mr. H. F. Bidder. 8 p.m.

INST. OF ELECTRICAL ENGINEERS: N. EASTERN CENTRE.—Rendezvous Restaurant, Pilgrim-street, Newcastle-upon-Tyne. Informal meeting. Discussion, "Electricity as a Heating and Warming Agent," opener Mr. L. E. Mold. 7 p.m.

INST. OF PRODUCTION ENGINEERS: SHEFFIELD SECTION.—Royal Victoria Hotel, Sheffield. "Optical Measurement in Engineering Production," Mr. A. A. Gigli. 7.30 p.m.

ROYAL INST. OF GREAT BRITAIN.—21, Albemarle-street, W.1. General meeting. 5 p.m.

SOC. OF CHEMICAL INDUSTRY.—At Chemical Soc., Burlington House, W.1. "Control and Measurement of Temperature in an Industrial Laboratory," Messrs. E. A. Cooke and J. C. Swallow. 8 p.m.

SOC. OF ENGINEERS.—At Geological Soc., Burlington House, W.1. "Reinforced Concrete: Its Application to Modern Housing," Mr. H. Kaylar. 6 p.m.

TUESDAY, DECEMBER 5TH.

CHADWICK PUBLIC LECTURES.—At Inst. of Mechanical Engineers, Storey's-gate, S.W.1. "Rural Sanitation," Mr. J. H. Coste. 8 p.m.

CHELSEA POLYTECHNIC.—Manresa-road, S.W.3. Distribution of prizes, diplomas, and certificates to students by the Viscount Leverhulme. 8.30 p.m.

INST. OF AUTOMOBILE ENGINEERS.—At Royal Soc. of Arts, John-street, Adelphi, W.C.2. "Technical Aspects of the Design of the 'Blue Bird' Racing Car," Mr. R. A. Railton. 7.45 p.m.

INST. OF ELECTRICAL ENGINEERS: SCOTTISH CENTRE.—At N. British Station Hotel, Edinburgh. Dinner, 6.30 for 6.45. Prof. F. G. Baily will introduce a talk, "Reminiscences of Early Days."

INST. OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND.—39, Elmbank-crescent, Glasgow, C.2. "Shipyard Methods and Lay-outs," Mr. G. Barrie. 7.30 p.m.

RAILWAY CLUB.—Broad-street Station Restaurant, E.C. Annual dinner.

SATURDAY, DECEMBER 16TH.

INST. OF ELECTRICAL ENGINEERS: N. MIDLAND STUDENTS.—Visit to Messrs. Marshall, Kay and Marshall, Dewsbury. 3 p.m.

MANCHESTER ASSOC. OF ENGINEERS.—At College of Technology, Manchester. Conversazione and dance. Reception 6.45 p.m.

MAIN LINE OIL-ELECTRIC LOCOMOTIVE.—In order to avoid any misunderstanding, Sir W. G. Armstrong, Whitworth and Co., Ltd., ask us to state that the main line oil-electric locomotive, described in our issue of November 17th, has not been purchased by the London and North-Eastern Railway, as might be inferred from the title of our article, but is being put into a regular trial service on that railway.

"BRITISH RUSSIAN GAZETTE" LUNCHEON.—At the fifth *British Russian Gazette* luncheon, which will be held on Thursday, December 7th, 1933, at 12.45 p.m. for 1 o'clock, at the Connaught Rooms, Sir Francis Goodenough will give an address on "Trade with Russia." This luncheon is being arranged for business men and manufacturers in order to further the development of British trade with Russia. Intending guests are asked to make application for tickets not later than December 4th to the British Russian Gazette and Trade Outlook, Ltd.

A Seven-Day Journal

Railway Contracts.

The Great Western Railway Company, which is the biggest user of steel sleepers in the country, has decided to lay a further 27 miles of track with them. Orders have been placed with Guest, Keen and Nettlefolds, Ltd., for 100,000 steel sleepers, weighing 10,500 tons, 10,000 tons of chairs and 25,000 tons of steel rails. The Lancashire Steel Corporation, Ltd., has also received an order for 5000 tons of steel rails. These orders represent a total of 50,000 tons of steel for use during the company's 1934 relaying programme. It has already 400,000 steel sleepers laid in its main, relief, and branch lines, equal to 185 miles of track, in the following districts:—London, Bristol, Thornton, Plymouth, Newport, Cardiff, Neath, Gloucester, Wolverhampton, Shrewsbury, and Oswestry. The Southern Railway Company announced on Monday last, December 4th, that work will be at once begun on a second pair of passenger and cargo sheds at the new Southampton Docks. The sheds will have a length of 1274ft. The contract for steel work has been let to E. C. and J. Keay (1926), Ltd., of Birmingham, and a contract for walls, roofs, &c., with Sir Robert McAlpine and Sons, of London. The cost of the new sheds will be about £50,000 and their construction will employ about 400 men during the winter months.

The Merchant Navy.

In the House of Commons, on Thursday last, November 30th, Lieutenant-Colonel Moore-Brabazon presented a petition drafted under the auspices of the Officers (Merchant Navy) Federation, asking that a public inquiry be set up to report upon the conditions of service of certificated navigating and engineer officers in the British merchant navy. The petition, which was signed by over 12,500 masters, navigating and engineer officers, and by over 10,000 members of the public, was brought to Westminster on the tug "Britannia," which came up the river to Westminster Pier. It prays "That the well-being of the merchant navy, being a matter of national concern, a public inquiry be set up to report upon conditions of service of certificated navigating and engineer officers in the British merchant navy, with special regard to training, contract of employment, leave, remuneration, unemployment and health insurance, representation, recognition, employment of uncertificated and foreign officers in British ships, benevolent work and pensions, and the provisions of the Merchant Shipping Acts, 1894 to 1921, in so far as such Acts affect certificated officers." The question is also to be raised in the House of Lords.

The Forth Road Bridge.

In a Journal note of October 6th we outlined the proposals of the Minister of Transport with regard to the construction of a road bridge over the river Forth from Kincardine-on-Forth to Higgins' Neuk. It may be recalled that the Ministry of Transport will give a grant of 75 per cent. of the estimated cost of £327,000. Work has now been begun on the bridge, the contract for the construction having been let to the Cleveland Bridgebuilding and Engineering Company, Ltd., of Darlington. Over 4000 tons of steel will be used in the structure. The bridge has been designed by Sir Alexander Gibb and Partners and will have twelve spans, each of 50ft., with a horizontal swing span in the navigable channel of the Forth, providing two openings for shipping, each of 150ft. clear width with about 30ft. clear headroom at high water. The roadway has a total width of 40ft. over parapets and comprises a 30ft. carriageway with 5ft. footpaths on either side. The spans will be supported on cylinders of reinforced concrete sunk into the river bed. At the end of last week the engineers and contractors surveyed the site and it is expected that the work of excavation will begin before Christmas. The new bridge will be approached on either side by easy gradients from the arterial roads on either side of the bridge. When completed, the new bridge will reduce the mileage between Glasgow and Fife by one third, and it will avoid the congested roads near the town of Stirling.

The Smithfield Club Show.

Following our usual practice, we paid a visit to the annual Show of the Smithfield Club, commonly known as the "Cattle Show," which opened at the Royal Agricultural Hall on Monday, the 4th, and closes to-day. As most engineers know, the Show provides an occasion when engineers manufacturing agricultural machinery can display their products to advantage, for interested visitors come from all over the country and are not greatly incommoded by the sight-seeing public. All the marginal space of the two halls and the gallery is given up to machinery and implements, and in the past good displays have been provided. This year, however, the Show is disappointing from an engineering point of view. Apart from the absence of several firms which have exhibited for many years past, but have recently gone out of existence, there are many absentees, and there is only one stand which retains its familiar appearance. There are to be seen one or two other names that are known throughout the engineering world, but several of them have become hyphenated. The result of the absence of the heavier engineering firms is that the makers of agricultural implements, windmills, and the like have encroached greatly on the space. The makers of small refrigerating plant also are much in evidence, fostered, of course, by the new food preservation regulations. It is rather remarkable that electrical farming appliances—that is to say, for the application of electrical power to general purposes—are not represented, as we are led to believe that the policy of the Central Board is to foster the use of electricity on the land. There are certainly a few appliances, such as milking machines and refrigerators driven by electric motors, but there is no evidence of concerted action to encourage the policy. There is one other characteristic about the Show and that is the advent of the pneumatic tire for farm vehicles. It is even, in two cases, fitted to oil tractors. Track-tractors are also represented, and there is a new tractor wheel equipped with spuds specially shaped for getting a maximum grip in soft ground.

Industrial Psychology.

Two investigations in engineering factories are described in the annual report of the National Institute of Industrial Psychology, which has just been issued. In the first works, which manufactures motor accessories, the Institute tackled the problem of installing a new system of stock control, better suited to the needs of the factory than the old system. It also investigated in detail the service offered to customers at the factory service depôt, compiling a booklet of service notes for reception clerks which, it is hoped, will enable them to avoid most of the awkward situations which are liable to arise with customers. The methods of staff management adopted when two shops in the factory were amalgamated had produced unsatisfactory relations between the various grades of employees. The Institute was successful in removing the friction and discontent, mainly by improving the methods of staff control. The Institute is also working in the repair factory of the Post Office Stores Department. Here the problems are concerned mainly with congestion of space and the strained postures of the men working on certain types of apparatus. The Institute has planned new lay-outs, and it has constructed storage cabinets and adjustable tool holders so that all the things required on the job are ready at hand. It has recommended the use of platforms so that the men need not stoop so much in the course of their work.

The Unemployment Returns.

As normal seasonal effects usually result in a decline of employment in the month of November, it is all the more gratifying to find from the returns of the Ministry of Labour that in November there were 31,000 more persons at work than during the preceding month. As compared with the corresponding month a year ago, the figures show a decrease of unemployment by as much as 597,000. On November 20th, 1933, the numbers of unemployed persons on the registers of employment exchanges in Great Britain were 1,855,808 wholly unemployed, 340,135 temporarily stopped, and 84,074 normally in casual employment, making a total of 2,280,017. Apart from such trades as building, public works contracting, &c., which are normally adversely affected in November, the improvement is general. Coal-mining, cotton, iron and steel, and general engineering all show substantial decreases in unemployment, and the figures for shipbuilding and pottery also exhibit a good, though not so large a decline. One of the features of the returns is that increase in employment is particularly noticeable in the Midlands and the North of England.

The Navy and Coal Fuel.

From time to time we have referred in these columns to the Back-to-Coal Movement, and particularly to the desire of South Wales coal producers to see the Navy revert to coal firing. In a written answer to a question in the House of Commons last week, Sir Bolton Eyres Monsell, First Lord of the Admiralty, stated that none of his Majesty's ships is fitted to burn alternatively oil or coal, and that, in view of the many disadvantages attendant upon the use of a dual system from the standpoint of Fleet efficiency, it is impossible for the Board of Admiralty to adopt such a system, either for present or future vessels. The Minister said that the use of coal by the Navy had been frequently considered from the standpoint of the coal industry, but that even if the Navy was to burn coal exclusively, its consumption would not exceed ½ per cent. of the total national output of coal. It has since been pointed out, however, that while the figure given by Sir Eyres Monsell is true, the coal consumed by the Navy would be best steaming coal, and should be more properly related to the output of that particular class of coal, which is about 30,000,000 tons p.a. On this basis, naval requirements would involve one-thirtieth of the national output, and would find permanent employment for over 3000 miners. The cost of converting the present oil-fired system used in the Navy to coal-firing is estimated by the Minister as at least £35,000,000.

A Famous Clyde Steamer.

On Thursday, November 30th, the well-known L.M.S. Clyde passenger steamer, "Caledonia," carried through her final sailings. For many years she has been employed on the service between Gourock and the Holy Loch piers, and as she left these piers on Thursday afternoon, farewell blasts were blown on the siren. On arrival at Gourock, she disembarked her final complement of passengers and proceeded to Albert Harbour, Greenock. In due course she will probably pass into the hands of the shipbreakers. Meanwhile, her service has been taken up by the steamer the "Marchioness of Breadalbane." The "Caledonia" was built in 1889 to the order of the Caledonian Steam Packet Company for service between Gourock and the coast resorts by John Reid and Co., of Port Glasgow, and was engined by Rankin and Blackmore with tandem compound diagonal engines, supplied with steam at 99 lb. pressure from two Navy-type boilers working under forced draught. The hull has a length of 200ft., a beam of 22ft., and a depth of a little over 7ft. The "Caledonia" retires after over forty years' service.

A Railway Wagon Census.

At four o'clock on Sunday, December 3rd, a periodical census was taken of the 650,000 or more railway-owned wagons in service at every station, goods depôt, and siding in Great Britain, and the 362,000 sheets which are provided for covering open wagons. Special staffs were employed, which patrolled the whole of the 51,000 miles of British railway track, each man being assigned a definite section. Special provision was made for the wagons actually in transit at four o'clock when the census was taken. On the London, Midland and Scottish Railway the total census included some 300,000 vehicles and over 150,000 railway-owned sheets, for which it was necessary to issue 23,000 census forms to the railway staff. The returns of the census are made to headquarters, where they are checked, in order to enable the necessary disposition of rolling stock between the different railway companies to be made by the Railway Clearing House.

Southern Railway Electrification.

On Tuesday last it was announced that the Southern Railway Company had decided to extend its main line electrification scheme from Wivelsfield and Brighton to Eastbourne and Hastings, and from Haywards Heath to Horsted Keynes, at a cost of £1,750,000. The work will be put in hand almost immediately and the extension is expected to be ready for operation early in 1935. By the use of electric traction it will be possible to increase the train mileage over these lines by some 45 per cent. The equipment of the new sections will be generally similar to that employed on the Brighton and Worthing sections of the line, and British firms will benefit considerably from the contracts which will be placed. The new rolling stock which will be required will include seventeen six-car units, five four-car units, and eighteen three-car units, with the necessary Pullman stock. The longer trains to be employed will necessitate platform extensions at London Bridge, Lewes, and Eastbourne, and alterations to the permanent way at Bexhill Central. When the work has been completed the Southern Railway Company will have 442 miles of electrified lines with a track mileage of 1146. It is also announced that the Southern Railway Company will apply to Parliament during the present session for powers to construct a new loop line between Folkestone and Dover.

Return of the Royal Scot.

On Tuesday, December 5th, the "Royal Scot" arrived at Tilbury from Canada on the Canadian Pacific cargo liner "Beaverdale." After being renovated and refitted at Crewe the train, which has made such a successful tour of the United States and Canada, will be given an official welcome at Euston Station. According to Mr. C. O. D. Anderson, who was in charge of the train throughout the tour, all who inspected it were impressed by the superiority of British workmanship. At the end of her tour the engine, after running over 11,190 miles, was in as good condition as when she started, and could be running again in five days. North American engineers were particularly impressed, Mr. Anderson stated, with the absence of any mechanical breakdown, and the fact that on arrival at a station after a run there was no necessity to go round greasing dangerously heated bearings. Grease lubrication is generally employed both on Canadian and American locomotives, but it is noteworthy that since the visit of the "Royal Scot" the Canadian Pacific Railway Company has adapted a locomotive for oil lubrication. During the tour the train was inspected by no less than 3,021,601 people, and over 500 electric light bulbs were carried away as souvenirs, while more than 1000 signatures were scribbled on the roofs of the carriages; hence the need for renovation and refitting before the official reception.

Vertical-Lift Drawbridges.

By E. E. R. TRATMAN.

No. I.

A TYPE of drawbridge which has come into extensive use in recent years in the United States, for both railways and highways, is the vertical-lift bridge, in which the movable span travels vertically between tall towers while retaining its horizontal position. This span is suspended by means of cables hanging over sheaves or pulleys at the tops of the towers, the cables having one end fastened to the span and the other end to a counterweight moving in the tower. What is believed to be the largest movable span in existence is of this type, being the 534ft. lift span in the highway bridge across the Delaware River at Burlington. This important structure, with its lift span in the raised position, is shown in Fig. 1. The vertical-lift principle is old, but its extensive application to large modern structures is a notable development in American bridge engineering.

In other countries this type of drawbridge has been adopted only to a very limited extent for modern bridges. The idea originated apparently in connection with the design of bridges crossing canals at a low level and requiring some means of lifting them to permit the passage of boats. Both the length of span and height of lift were small in such cases.

An early example in England was a single-track bridge built by Mr. Jacomb Hood to carry a line of the London, Brighton and South Coast Railway across the Surrey Canal. This was a deck plate girder structure of 22ft. 6in. span, with a vertical travel of 10ft., and was operated by two men at hand winches. In 1909 a plate girder lift span of 27ft. 9in. was built to give a passage through a concrete jetty in the harbour for submarines at Haslar. The first large bridge of the lift type in Great Britain is the one over the Tees at Middlesbrough, which is to be opened to traffic shortly. It is a highway bridge, with a length of 250ft., having a roadway 38ft. wide and two cantilevered footpaths, each 9ft. wide. It will give a clear headroom of 30ft. when lowered and 120ft. when raised. This 250ft. lift span is flanked on each side by five approach spans, the total length of the bridge being 4920ft. The consulting engineers are Messrs. Mott, Hay and Anderson, and Dorman, Long and Co. are the contractors for the steel superstructure. Several small bridges of this type, crossing canals, have been built in France.

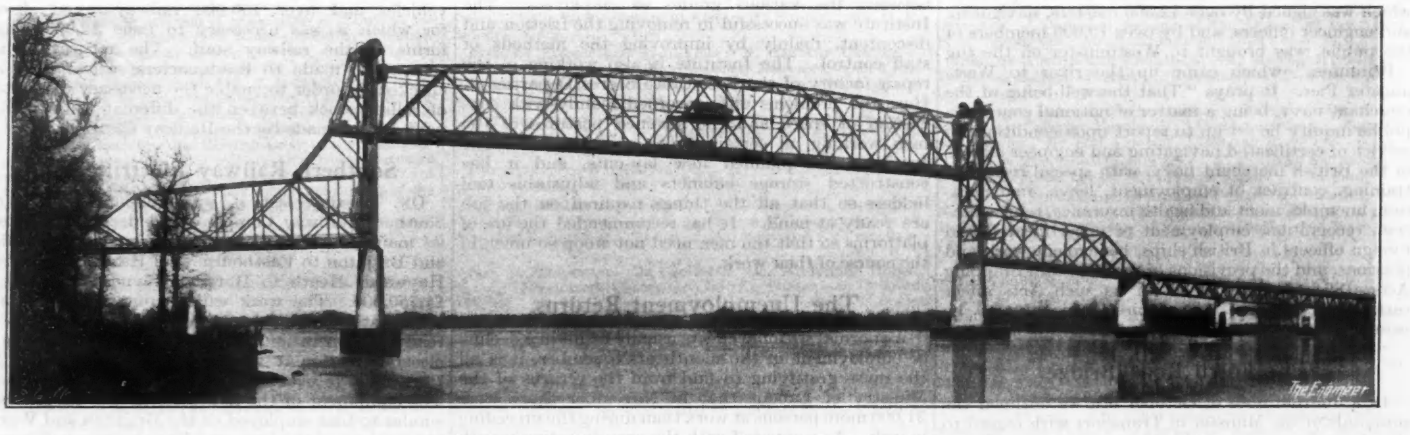

FIG. 1—LIFT SPAN OF THE DELAWARE RIVER BRIDGE

In America, between 1870 and 1880, a number of such bridges were built over the Erie Canal by Mr. Squire Whipple. In these structures, however, the towers carried a fixed overhead truss span and the lifting deck had hanger rods which telescoped in the posts of the trusses and were attached to counterweighted cables. This arrangement has been applied in recent years to double-deck bridges, having the decks operated independently, as will be noted later.

A Typical Lift Bridge.

A typical design of a vertical-lift bridge is given in Fig. 2. This drawing represents two recent duplicate bridges on a public highway, which crosses the Hudson River at Albany, and again at Troy, a few miles further upstream. The clearance above water is 35ft. 6in. with the span lowered and 135ft. with the span raised. Although not the longest, these are by far the heaviest bridges of this type, for with a length of 341ft. between end bearings, the weight in each case is 2730 tons, exclusive of counterweights. This weight includes 1360 tons of structural steel, 1110 tons for the concrete paving, and 260 tons for the machinery, cables, electric equipment and petrol engine as a stand-by unit. The deck or floor provides a roadway, 42ft. wide between kerbs, and two 6ft. walks outside the trusses, all paved with concrete. The roadway is designed to carry 20-ton motor trucks.

Cables attached to the ends of the bridge pass over sheaves on the towers and down to the two counterweights, which together equal the total weight of the lift span. There are ninety-six cables, 2⅜in. in diameter, the forty-eight at each end being divided into six groups of eight cables, each group having its own grooved sheave on the tower. This grouping of the cables is shown by the cross section in Fig. 2. Variable voltage control is used for the two main motors of 250 H.P., requiring the use of a motor generator set. The machinery, mounted in a house on the lift span, drives two drums on each side of the bridge, from which the operating cables lead to guide sheaves at the ends of the span. Thence they divide, a set of up-haul cables extending to the top of the tower, and another set of down-haul cables extending to the foot of the tower. Current for the motors is taken from power cables suspended between the towers and upon which ride collectors mounted on a triangular steel frame pivoted on top of the machinery house.

The system of operation described above is used on a majority of the vertical-lift bridges, but other systems are in use and will be dealt with later.

Examples of Lift Bridges.

Four typical bridges of the vertical lift type are shown in Figs. 5 to 8. The Suisun Bay bridge of the Southern Pacific Railway (Fig. 5, page 572) has a 328ft. double track lift span of about 1680 tons weight, with a vertical travel of 65ft., increasing the headroom from 70ft. to 135ft. This lift is made in 90 seconds by two electric motors of 150 H.P. In the Illinois River highway bridge at Hardin (Fig. 6) there is a lift span of 309ft. length, with a lift of 57ft., giving a clearance of 8ft. when lowered and 65ft. when raised. In the James River bridge (Fig. 7), also a highway structure, the 300ft., 470-ton lift span has a vertical travel of 95ft., increasing the normal clearance of 53ft. to a maximum of 148ft. The lift span of the 7-mile highway bridge across San Francisco Bay, at San Mateo (Fig. 8), has a length of 298ft., and a vertical travel of 100ft. Its weight is 665 tons, including 43 tons of operating machinery. The view shows the span being floated into position between the towers. The footpath above the trusses gives access to the guide sheaves which support the operating cables leading from the machinery house to the end of the span.

American Vertical-Lift Drawbridges.

White River	De Vall's Bluff	Chicago, R.I. and Pacific Ry.*	182½	361

* Single track. † Double track. ‡ Two double-track bridges side by side. § Four tracks. ‖ Three tracks.

Although the first large bridge of this type was opened at Chicago in 1894, it was not followed by another for some years, and it is within the past decade that such bridges have been built in large numbers. Some of the larger of these structures are listed in the accompanying table. The longest span, 534ft., is in the Delaware River highway bridge already mentioned. The longest railway lift bridge is the 408ft. span in the bridge carrying the Missouri, Kansas and Texas Railroad across the Missouri River near Boonville. Next to it in length come the 341ft. lift spans in the two highway bridges over the Hudson River, the 331½ft. lift span of the Pennsylvania Railroad bridge over the Hackensack River at Jersey City, and the 322ft. lift span in the long bridge carrying the Pennsylvania Railroad and the Lehigh Valley Railroad across Newark Bay, near New York.

An unusual feature of the Hackensack River crossing is the fact that the Pennsylvania Railroad has two parallel bridges—one, with the 331½ft. lift span, for the passenger lines, and the other, with a 206ft. lift span, for the freight or goods lines; while close at hand is a highway bridge with a 206ft. lift span. Of the bridges over the Calumet River, with 210ft. lift spans, the New York Central Railroad has a single bridge carrying four lines of rails, while the Pennsylvania Railroad has two double-track bridges side by side. This railway uses the same arrangement for the two 273ft. lift spans on its four-track line over the Chicago River. The heaviest lift spans are two of 341ft. span in duplicate bridges crossing the Hudson River at Albany and Troy, weighing 2730 tons each.

From such large bridges the lift spans range in length downward to an 82ft., 30-ton, through-truss span on a country road, and a 50ft. plate girder deck span carrying a railway across a drainage canal. Both of these spans are equipped only with hand-power operating mechanism, as they are opened at very infrequent intervals. In fact, the lifting girder span is provided simply to permit the passage of dredges used occasionally in cleaning the canal.

Advantages of Lift Bridges.

Vertical-lift bridges, like bascule bridges, give a clear channel, unobstructed by a pivot pier, as usually required for swing bridges. By moving in a vertical direction—also like bascule bridges—they avoid interference with adjacent shore property, while with swing bridges a certain amount of water front is rendered useless by the necessity of keeping a clear space for the swinging of the span. The operating time of a lift span is about one-third that of a swing span, and is less subject to difficulty or delay by high winds. There is also less strain in the moving structure of a lift span than in a swing or bascule span, so that the design of the lift span is much simpler. In fact, there is little difference between a lift span and a fixed span of the same weight, except that a top cross girder is required at each end for the cable attachments. One long bridge over a river with a shifting channel is so designed that the towers and lift span can be transferred to the position of one of the present fixed spans, if that should become necessary. The comparative cost of the different types of drawbridges can be determined only for each individual enterprise, since the cost depends so much upon local conditions.

It has been pointed out by Mr. O. E. Hovey, consulting engineer, in a paper before the American Society of Civil Engineers, that vertical-lift spans have no positive reactions from dead load at either end when closed, and end locks are required to prevent vertical play under traffic. He says: "When the span is raised the centre of wind pressure is higher than for bascules and general stability must be provided to meet this condition. This may make it necessary to increase the width of the bridge and the size of the piers and foundations. The counterweights weigh the same as the span, thus being much lighter than those for bascule bridges of the same length. The counterweights are usually attached to the ends of the span by wire ropes extending up and over large sheaves, which turn on trunnions on top of the towers. In some designs articulated links (connected to rocking levers) are used for this purpose. In either case, however, the mechanical parts are always under stress and must be carefully maintained. Moreover, repairs and renewals are difficult and expensive."

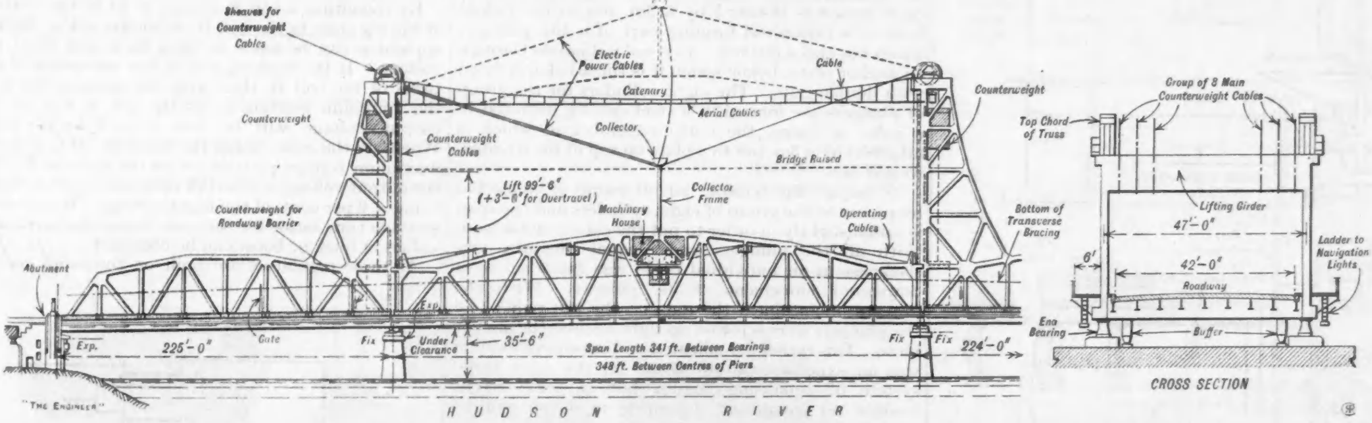

FIG. 2—DESIGN OF TWO VERTICAL-LIFT DRAWBRIDGES ACROSS THE HUDSON RIVER AT ALBANY AND TROY

"Where the waterway is wide, the length of the fixed spans is greater than would be required with swing spans. Also, the operating machinery must accelerate a greater mass than in a swing span, but less than in a bascule. However, the resistance from wind pressure is small, and the power required is intermediate between swing spans and trunnion bascules. A vertical-lift bridge is less expensive than a bascule, the cost being intermediate between that for swing spans and bascules."

DESIGN OF VERTICAL-LIFT BRIDGES.

Special provisions for the design of vertical-lift bridges are included in the standard specifications for movable bridges, as adopted by the American Railway Engineering Association. These provisions include formulæ for the strength of wire cables that are bent by passing over sheaves. The total unit tension in the counterweight ropes is not to exceed one-fifth of the specified unit ultimate strength of the rope, and the unit tension from the direct load is not to exceed one-tenth of that ultimate strength. For the operating ropes these limits are one-third and one-sixth of the ultimate strength. The weight of the counterweight cables must be balanced by chains hung beneath the counterweights. Unless otherwise specified, these balancing chains are to consist of cast iron links connected by steel pins in cored holes in the links. Wind pressure is to be assumed as 15 lb. per square foot on the exposed surface of the floor and the two trusses.

The diameters of cable sheaves are to be not less than seventy-five times the diameter of counterweight cables or forty-five times for operating cables, but ninety and fifty times the diameter, respectively, are considered preferable. Counterweights must be so divided into parts that no part is hung from more than sixteen cables, the cables of each group being attached to its part of the counterweight by an equaliser. However, in many recent bridges this use of equalisers has been eliminated by having all cables cut to length while under stress, as noted more fully later.

All cables are specified to be of improved plough steel and to consist of six strands of nineteen wires each, laid around a hemp centre. Their diameters are to be not less than 1in. nor more than 2½in. for counterweight ropes, and not less than ¾in. for operating ropes. The operating ropes are to have at least two full turns on the drum when the span is in its full open or full closed position, and it is recommended that the number of turns should be sufficient to develop the ultimate strength of the rope by friction, the coefficient of friction being taken as 0·20. A turnbuckle, clevis, or other device must be provided for taking up slack in the rope. In counterweight ropes the deviation from the vertical should be as small as possible, the deviation from the plane through the centre of the groove in the sheave not exceeding 1 in 40. These separate requirements for operating cables and counterweight cables are ineffective in the latest designs of vertical-lift bridges, in which the counterweight cables serve also as operating cables, as described later in this article.

HALSTED-STREET LIFT BRIDGE, CHICAGO.

The first important modern bridge of the vertical lift type was the Halsted-street Bridge at Chicago, over the Chicago River, which was opened in 1894, replacing a swing bridge that had been damaged by a steamer. The lift span was of the through-truss type, 138ft. long, giving a clear waterway opening of 130ft.; it had a 36ft. roadway and two 7ft. sidewalks outside the trusses. The clearance above water level was 14½ft., with the bridge closed, and 155ft. with the bridge raised to its full height. The two pairs of steel towers were about 217ft. high above the water line and had the very unusual feature of being connected at their tops by truss struts, in order to prevent any inward deflection or inclination under the load of the span in its suspended position. This overhead connection, which served also to carry idler sheaves for the operating cables, is used only in very few such bridges. It has been included in some short canal bridges, and in a 214ft. highway span at Tacoma it was adopted in order to carry a water main across the channel.

Separate groups of cables were used for the counterweighting and the operating functions. At each end of the span were eight 1½in. cables, doubled or looped and hung over the sheaves on the tower, both ends of the cable being attached to the span, while the loop or bight hung in the tower. From 15in. equalising sheaves riding in the bights of the cables the counterweight was suspended. In this way there were sixteen counterweight cables attached to each end of the lift span and passing over pulleys 12ft. in diameter on the towers. The weight of these cables was balanced by chains attached to the bottom of the counterweight and the bottom of the lift span. The total weight of the span was nearly 300 tons, and as this was almost exactly balanced by the counterweights, the operating machinery had only to overcome the slight excess of dead load, the friction, and the varying dead load of dirt and snow. This machinery was designed, however, to lift a 1-ton excess load.

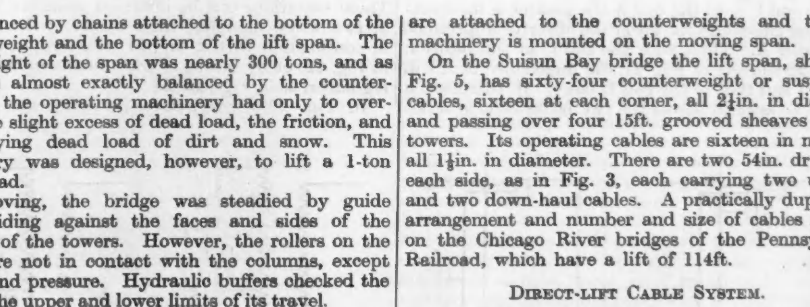

FIG. 3—ARRANGEMENT OF COUNTERWEIGHT AND UP-HAUL AND DOWN-HAUL CABLES

In moving, the bridge was steadied by guide rollers riding against the faces and sides of the columns of the towers. However, the rollers on the sides were not in contact with the columns, except under wind pressure. Hydraulic buffers checked the span at the upper and lower limits of its travel.

A steam hoisting plant was built under the north approach, two vertical inverted engines driving a shaft having two 6ft. spirally grooved drums, on each of which were eight ⅞in. operating cables. Electric motors replaced the steam engines in 1907. These cables passed under 6ft. guide sheaves at the bottom of the tower and over similar sheaves at the top of the tower. Four of the cables then led down to an attachment on the north end of the span; the other four were led across the top strut to the opposite tower, and then down to an attachment on the south end of the span. From the second drum, eight cables led up to the top of the north tower and four of them passed down to be attached to the counterweight in this tower. The other four continued across the top strut and down to the counterweight in the south tower. In this way the span was raised by direct pull and was lowered by pulling up the counterweights.

This Halsted-street lift bridge was replaced in 1931–32 by a bascule bridge, as its width and strength were not adequate for present-day traffic and vehicle loads. Although some of the counterweight cables had been in use for twenty-eight years, they were in good condition, except at the attachments to the lift span, which were of a type now obsolete.

CABLE SYSTEMS.

Until about six years ago three independent sets of cables were used at each end of these lift bridges—(*a*) the suspension cables attached to the sheaves and the counterweights; (*b*) and (*c*) the up-haul and down-haul operating cables wound upon driving drums, usually mounted in a machinery house built on the lift span. Equalising devices were provided at the attachments of the counterweight or suspension cables in order to maintain a uniform tension in the several individual cables. The operating cables passed over guide sheaves on top of the span to end sheaves, where they diverged. The hoisting or up-haul cables (*b*) passed under the end sheave and up vertically to attachments at the tops of the towers; the lowering or down-haul cables (*c*) passed over the end sheaves and down to similar attachments at the bottoms of the towers. The attachments were long-threaded eye-bolts, permitting adjustment of the length of the cable. This cable arrangement is illustrated by the diagram Fig. 3, and it will be seen that the span was positively pulled up or down according to the direction of rotation of the drums. It differs from that of the Halsted-street bridge in that no operating cables are attached to the counterweights and that all machinery is mounted on the moving span.

On the Suisun Bay bridge the lift span, shown in Fig. 5, has sixty-four counterweight or suspension cables, sixteen at each corner, all 2¼in. in diameter, and passing over four 15ft. grooved sheaves on the towers. Its operating cables are sixteen in number, all 1⅛in. in diameter. There are two 54in. drums on each side, as in Fig. 3, each carrying two up-haul and two down-haul cables. A practically duplicated arrangement and number and size of cables is used on the Chicago River bridges of the Pennsylvania Railroad, which have a lift of 114ft.

DIRECT-LIFT CABLE SYSTEM.

A radical departure from this arrangement of using three separate groups of cables was the utilisation of the counterweight cables to serve also as operating cables by the seemingly simple process of applying power to the big sheaves on top of the towers. This greatly simplifies the cable system and relieves the lift span of the weight of operating machinery. In one large lift bridge having the older arrangement, the total weight of the lift span was about 1800 tons, of which about 125 tons was for the machinery, cables, and machinery house. The newer system was used first on the White River bridge, built in 1927, by the Chicago, Rock Island, and Pacific Railway.

The White River bridge, at De Valls' Bluff, is a single-track structure having a through-truss lift span of 182ft., with two flanking spans of 150ft., in which are incorporated the 100ft. towers carrying the cable sheaves. At each end of the lift span is a transverse portal girder or lifting girder to which the cables are attached. In addition to the novel direct-lift system, this bridge is notable for a hydraulic equaliser system in the cable attachments.

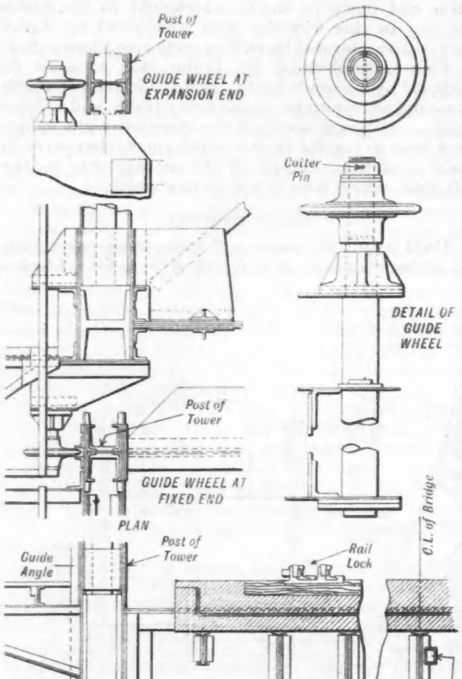

FIG. 4—GUIDE WHEEL ARRANGEMENT

At each corner of the White River lift span eight 1⅝in. cables are attached in fan shape to the lifting girder, which has connection plates with holes for 3in. pins, which pass through the forked ends of the cable sockets. The eight cables are brought together by a clamp about 6ft. above the girder, continuing then vertically to the grooved sheave on top of the tower and hanging down for attachment to the counterweight box, which moves in guides in the tower. These sheaves are 5ft. 6in. in diameter, grooved for the eight cables and shrouded on each side. On the inward face of the sheave is bolted a circular rack. At the top of the tower, two pairs of 25 H.P. electric motors drive through trains of spur and bevel gears to a single horizontal shaft, which carries at each end a pinion gearing with the circular rack on the cable sheave.

The hydraulic equalising device, already mentioned, forms the connection between the cables and the counterweight box. Here the flat tail of each cable socket is fastened by a 3in. pin to the forked head of a piston-rod forming part of a 4in. plunger, which has also a tail rod. This tail rod passes through an anchor plate, below which it is threaded and fitted with double nuts. The eight cylinders for the group of plungers are formed in a steel casting mounted in a yoke or frame, the bottom member of which is attached by a 3in. pin to a plate on top of the counterweight box.

To adjust the tension, an oil pump is connected by piping to the group of eight cylinders and the span is raised slightly in order to put the cables under load. With all the plungers under equal pressure, any slackness in an individual cable was taken up by a downward movement of its plunger. With the pressure maintained, the nuts on the tail rods of all the plungers were screwed up tight against the anchor plate. This rather complicated and expensive method was an experimental substitute for the more usual system of equalising beams, but in some recent bridges no equalising system is used, as will be explained later.

BRIDGE GUIDES.

To steady the bridge when moving, and to provide a bearing against wind pressure, four guide wheels at the corners of the lift span ride against the outer side faces of the main posts of the towers. In the guide wheel arrangement of the Des Plaines River railway bridge, shown in Fig. 4, a 26in. wheel with 1½in. rim is carried in an extension of the bottom chord at each corner of the span. At the fixed end of the span, the two wheels ride in grooves formed by two angle irons, 4in. by 4in., riveted to the sides of the tower posts. At the expansion end there are no grooves, the wheels riding upon the posts. Normally, these wheels stand ⅜in. away from actual contact.

(To be continued.)

A.C. Voltage Regulators.

No. III.

(Continued from page 542, December 1st.)

THE Ferranti patented moving coil regulator was described briefly in our issue of February 19th, 1932, but it cannot be neglected in this series of articles. It comprises, as shown in Fig. 21, a two-legged core with coils A and B and a short-circuited coil C free to move up and down the leg between the coils A and B. As the moving coil C is entirely isolated, no flexible connections or slip rings are required. Assuming that a voltage is applied to the coil A only, the resulting current in the coil will, of course, be dependent on its impedance, which is determined by the position of the coil C, for this coil may be regarded as a gate serving to prevent the passage of magnetic flux through it. The closer the moving coil C is to the coil A the greater is its short-circuiting effect and the lower the effective impedance of the coil A. Thus, with the coil C in the position shown on the left of Fig. 21, the impedance of A will be small and that of the coil B large. If, therefore, a voltage be applied across the two latter coils in series the greater part of the voltage will appear across B and only a small part across the coil A, as indicated on the left of Fig. 21. But with the moving coil at the bottom of the leg, as shown on the right of this illustration, the greater part of the voltage will exist across the coil A. Under the conditions assumed in this particular case, and with an impedance variation of 20/1, the voltage across the coil B can be varied smoothly and uniformly from 5–95 volts by moving the coil C in the manner described. Only under exceptional conditions, however, such, for example, in testing transformers, is such a wide voltage variation necessary, a variation of 10 to 20 per cent. being sufficient on transmission and distribution circuits. These variations can be obtained from the regulator in two ways, namely, either by using the regulator in conjunction with a tapped transformer, as shown in Fig. 22, or by means of additional windings on the regulator, as in Figs. 23–25.

In Fig. 22 the regulator is connected across a portion of the transformer winding and by choosing suitable tappings any desired range of voltage variation can be obtained, the typical range indicated in Fig. 22 being 91–109. The second method, however, lends itself to more general application, as the regulator works without a transformer or other apparatus. In effect the voltage variation obtained in accordance with the method shown in Fig. 21 is stepped down to the desired value by means of an additional coil or coils connected in series with the line. The scheme giving boost only is shown in Fig. 23 and diagrammatically in Fig. 24, in which the voltage across the coil D will be a constant fraction of the voltage across the adjacent coil A, depending upon the turn ratio of the two coils. In the diagram Fig. 24 it is assumed that the coil A has ten times the number of turns D, and from the values marked on the diagram it will be seen that the output voltage varies from 100·5 in the minimum voltage position to 109·5 in the maximum voltage position. By reversing the coil D its voltage would be subtracted from the input voltage instead of added to it, and the secondary pressure would then vary from 99·5 to 90·5 volts.

By mounting a coil E similar to D at the bottom of the leg close to the coil B, as shown in Fig. 25, the apparatus can be made to both buck and boost the voltage. If the bucking coil E has one-tenth of the turns of the coil B, then with the moving coil C in the minimum position as on the left of Fig. 25 the output voltage will be $100+0\cdot5-9\cdot5=91$ volts. When, on the other hand, the moving coil C is in the maximum voltage position, as on the right of Fig. 25, the output voltage will be 109 volts, the total variation being ±9 per cent. of the input voltage. By selecting suitable turn ratios for the coils D and E any desired values of buck or boost can be obtained.

As these regulators are built on the same lines as static transformers, they can be designed for high voltages and heavy currents and they do not necessitate the use of series and shunt transformers. The smallest regulators for indoor operation may be air insulated and air cooled, but all others are oil immersed in plain, tubular or radiator tanks depending upon the capacity. Single-phase regulators have a core with three legs, the centre leg being wound and, in the case of small regulators, the moving coil is carried on a non-magnetic frame and is operated by a square-threaded shaft. A disc induction motor, as described in connection with the Ferranti mercury switch "on load" tap-changing gear provides the drive for automatic operation.

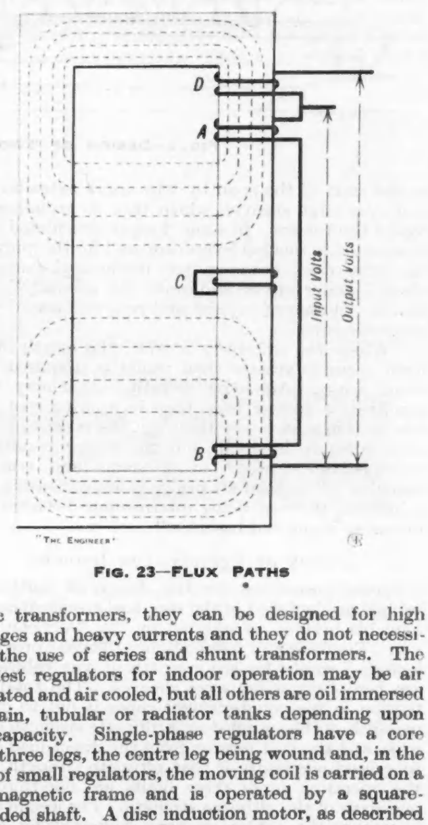

FIG. 23—FLUX PATHS

On larger size regulators the moving coil is supported at both ends, and is operated by two square-threaded vertical shafts, as shown in Fig. 26. The disc induction motor operates the moving coil through skew and worm gears, but on the largest regulators ordinary three-phase induction motors are employed. Three-phase regulators have rectangular cores, with three wound legs and the moving coils of each phase are held in a common framework operated by two square-threaded vertical shafts at either end of the core. As will be gathered from Fig. 27, the disc induction motor is mounted on the top of the core and drives a horizontal shaft which operates the square-threaded vertical shaft through worm and bevel gears. Except in the case of the largest regulators, all the mechanical operating gear, including the motor, is oil immersed. Complete with its mechanical gear, as a unit, the regulator is contained in a transformer tank, as illustrated in Fig. 28, which shows a fully automatic 20-kVA single-phase regulator for use on a 230-volt circuit and for giving a 10 per cent. boost. Regulators of all sizes can be designed for outdoor operation and are provided when necessary with cable boxes or hangers for pole mounting and a feeder pillar type of regulator is also made.

In order to reduce the current in the short-circuited winding, the coils A and B are connected in opposition,

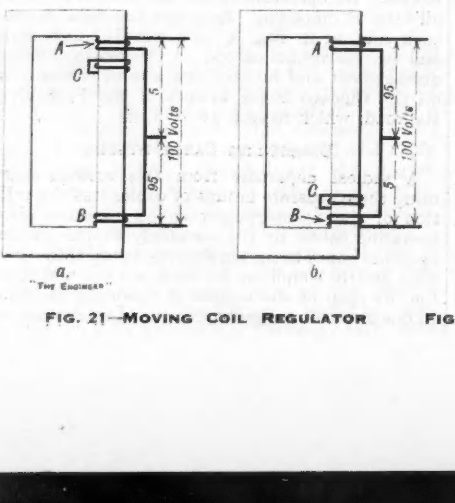

FIG. 21—MOVING COIL REGULATOR

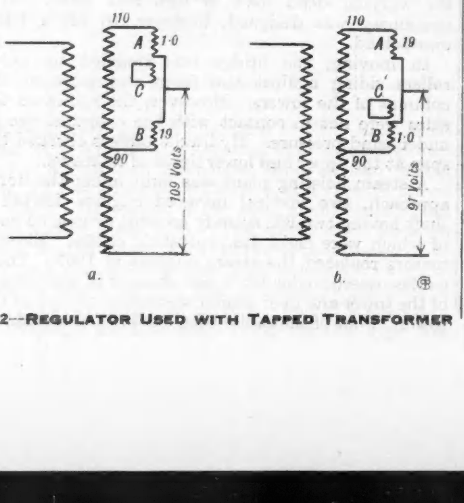

FIG. 22—REGULATOR USED WITH TAPPED TRANSFORMER

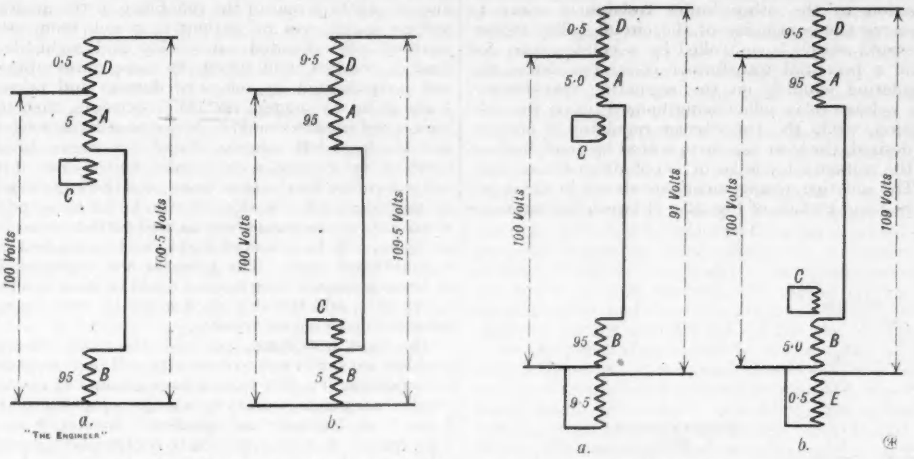
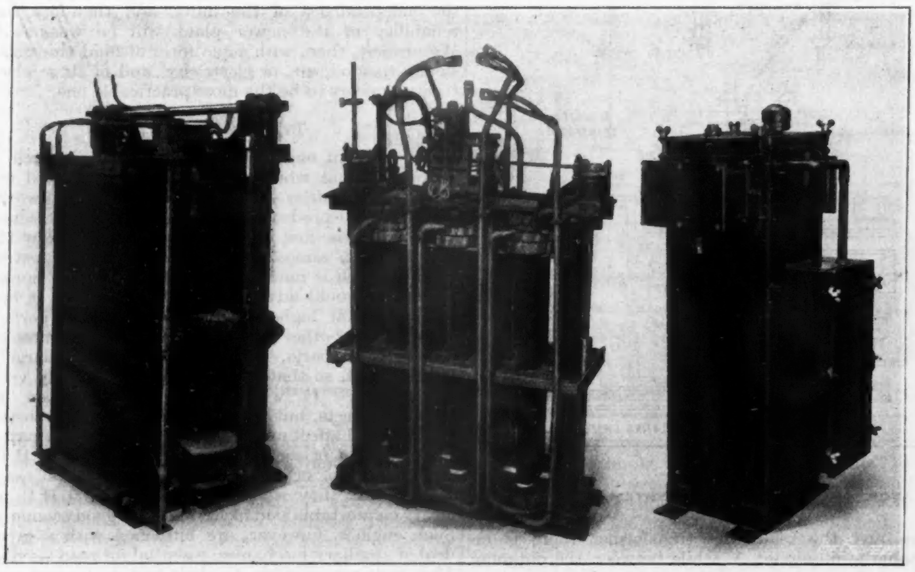
and for any position of the regulator there is no current in the short-circuited coil at no load. Under load conditions the current is proportional to the load current, but still independent of the regulator position.



FIGS. 24 AND 25—REGULATORS WITH ADDITIONAL WINDINGS

Losses on load and at no load vary with the current and flux densities and weights of iron and copper, and can therefore be varied in accordance with cost, as in any ordinary transformer. With a constant primary voltage the no-load current is practically constant for all positions of the regulator, and owing to the low flux density and large proportion of air path in the magnetic circuit, the magnetising current is said to be practically sinusoidal. Thus all troubles, such as telephone interference, condenser breakdowns, &c., are avoided. It is said that in standard regulators the maximum force on the moving coil in the worst position at full load is less than the weight of the coil itself, and the power required to move the coil is therefore very small. Thus for all except the largest regulators a disc type induction motor is sufficiently powerful.



FIGS. 26 TO 28—SINGLE AND THREE-PHASE FERRANTI MOVING COIL REGULATORS

On full load a regulator giving 10 per cent. voltage range the ratios of input to output kVA with load powers factor of 1, 0·95 and 0·85 are said to be 1·0025, 1·022 and 1·038 respectively with the regulator in the maximum voltage position. The makers point out that these figures are equivalent to those of an ordinary transformer having a magnetising current and impedance of 3½ per cent. in each case, and that it is easy to reduce them by reducing the reactance. With the values chosen, however, the regulators are claimed to withstand dead short circuits with infinite power behind them. The moving coil regulator is free from the phase displacement produced by a single polyphase induction regulator. Other advantages claimed are silent operation and simple control.

Owing to saturation of the iron under short-circuit conditions, the forces on the moving coil do not increase as the square of the load current. Nine circuits on a regulator with the moving coil in various positions are said to have no detrimental effects on the apparatus. A 5-kVA regulator, giving ±10 per cent. voltage variation on a 460/320-volt circuit, was connected on the primary side through a large step-down transformer to 6000-volt mains, and the power was such that the short circuit caused negligible voltage drop. Full primary pressure was therefore maintained on the regulator under short-circuit conditions, and short-circuit currents ranging from 10 to 19·5 times the full load value were obtained. Nevertheless, the short-circuit had no ill-effects on the apparatus. Provided simultaneous operation is ensured by coupling regulators mechanically, or, alternatively, by electrical control, they can be worked in parallel, but the regulators must, of course, have appropriate internal impedance valves in the same way as when ordinary transformers are connected in parallel. When regulated feeders are to be operated in parallel with unregulated feeders, the effect of feeder impedances and regulation on circulating currents and load distribution, as well as voltage, must be considered, and in special cases of parallel operation for tie lines or interconnection purposes, short-circuited compensating coils can be provided to give negligible impedances or controlled values over the regulator range.

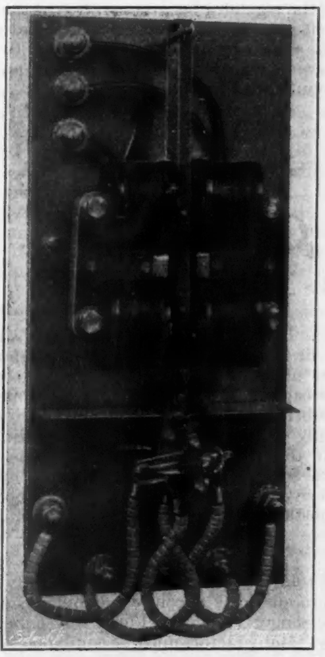


FIG. 29—MERCURY SWITCH CONTACTOR

The control panel is the same as that used for the mercury switch on-load tap-changing gear, described in the previous article and illustrated in Fig. 18. Similarly, the same type of motor is used for all Ferranti moving coil regulators, except the largest, and it is scarcely necessary to describe the control system here. The voltage relay associated with the control panel illustrated in Fig. 18 in the previous article operates directly on two small mercury switches in the motor circuit, and are controlled by two simple solenoids, as shown in Fig. 29.

TRANSFORMER BOOSTER REGULATOR.

The type of booster regulator shown in Figs. 30 and 31 has been made by the British Electric Transformer Company, of Hayes, Middlesex, for a considerable time. A regulating or auto-transformer is used to excite a second transformer, the secondary windings of which are connected in the lines to be regulated. It can be used in any existing circuit and, although the equipment is suitable for high voltages, the switchgear generally operates in a low-pressure circuit. Another advantage claimed is that the apparatus is self-contained and can easily be isolated from the controlled circuit by a simple arrangement of isolating switches. Fifty-eight of these regulators have recently been constructed for an overseas municipality for use on the distributors of a 400-volt three-phase 50-cycle four-wire system. They are designed to give ±10 per cent. regulation in 1 per cent. steps and for currents ranging from 250-1500 ampères, two sets being installed in each sub-station. The regulators are automatically controlled. At no load they keep the pressure at each sub-station constant and increase it somewhat as the load grows. One of the regulators is shown in Fig. 31. The switchgear is contained in a casing attached to one side of the tank which contains the regulating and series transformers. The main face plate regulating switch is an elaborate form of old-fashioned battery switch, but the face plate contacts are relieved of sparking by contactors in both the main and pilot brush circuits. A motor which derives its supply from the regulator serves for operating the switch, and the necessary maintaining switches, starting and stopping contactors are fitted on the panel adjacent to the switch. In the case of emergency the regulator may be operated manually by means of a handle, but normally a switch on the casing with "off," "raise," "lower," and "automatic" positions serves for hand operation. Relays required for automatically controlling each pair of regulators are separately housed in a light sheet steel casing and comprise voltage, time delay, and paralleling relays. There are also three rheostats for voltage setting and resistance and reactance drop compounding and various interlocking relays. The paralleling relay is connected between two potential transformers, which ensure that two regulators working in parallel remain in step.

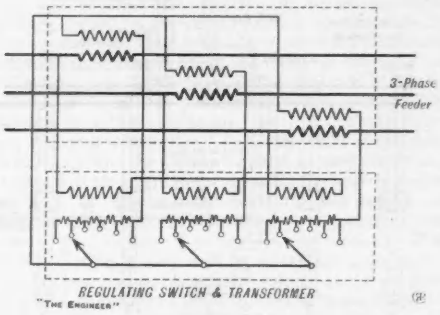

FIG. 30—BOOSTER CONNECTIONS

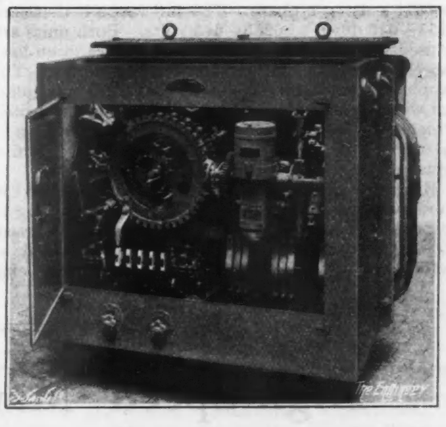

FIG. 31—BRITISH ELECTRIC TRANSFORMER REGULATOR

An example of the use of a transformer booster regulator in connection with a bulk supply is shown in Fig. 32. The voltage at a grid sub-station varied between the limits of 5610 and 6900, and it was therefore decided to install a feeder regulator to maintain a constant pressure of 6600 volts at the bus-bars of the supply undertaking's sub-station. Low initial cost, low running losses and noiseless operation are said to have been the factors which led to the choice of a transformer booster. Silent operation was very essential, as the regulator has had to be installed near a church. Another requirement was that the regulator should be capable of being put into or taken out of circuit without interrupting the supply. The equipment consists of the following apparatus :—(1) A regulating transformer designed for 6600/6255 volts auto-connected with a secondary winding for 341 volts per phase, divided into five equal sections ; (2) a series transformer designed for 645 volts between lines and insulated for 6600 volts with a secondary for 341 volts per phase. The full range is therefore 6255+645 down to 6255−645 volts. Both units are housed in a common tubular tank with the on-load tap-changing mechanism mounted on one side. The tappings from each of the five sections of the regulating winding are brought to the contacts of the switch which allows the voltage of the regulating winding to be applied to the series secondary winding in five equal steps.

By means of a change-over switch incorporated in the mechanism the polarity of the series winding in respect of the regulating winding can be reversed, so that the same regulation can be obtained as before, but in the reverse direction, the result being that the full variation is obtained in ten equal steps. As the actual circuit breaking takes place on auxiliary contacts, there is no arcing on the brushes or contacts of the selector switch. When changing from one position to the other buffer resistances serve to preserve the continuity of the circuit. The motor-operated switch is controlled by a voltage relay fed from a potential transformer connected across the regulating winding on the regulating transformer, the voltage relay pillar being housed inside the sub-station, while the transformer regulator is outside. If desired, the gear can be operated by push buttons in the voltage relay pillar in lieu of automatic control.

The isolating arrangements are shown in the upper right-hand portion of Fig. 32. Between the incoming lines and the regulating transformer there is an automatic oil circuit A, while between the outgoing side of the regulator and the outgoing bus-bars there is a non-automatic circuit breaker B. Between the incoming and outgoing bus-bars there is a three-phase air break isolator C, all these switches being contained in an outdoor switch kiosk. With the switch C closed and the regulator switch in the no-boost position the regulator is put into service by closing the circuit breakers A and B, when on opening the isolator C the regulator begins operation as the voltage relay is put into circuit. To take the regulator out of service the regulator switch is first moved to the no-boost position, isolator C is then closed, and afterwards circuit breakers B and A are opened.

"THE ENGINEER"

FIG. 32—TRANSFORMER BOOSTER REGULATOR ON BULK SUPPLY SYSTEM

High-Speed Marine Oil Engines.

By H. R. RICARDO, B.A., F.R.S., M.I. Mech. E.

THE lecture I am about to deliver in memory of the late Mr. Thomas Lowe Gray must deal with marine engineering, a subject in which I am indeed very interested, but about which I can claim no expert knowledge or experience. If therefore some of my statements and proposals appear outrageous, I must claim from you that tolerance which is the prerogative of either youth or inexperience. A cat may look at a king—presumably with an expression which no courtier would dare to assume. I am going to look at the marine engineer with the cynical stare of the cat, secure in the knowledge that he will not harm a mere layman.

To-night I am going to plead the case for the really light high-speed Diesel engine for marine propulsion. When suggesting to any shipbuilder the use of light high-speed engines in preference to the large heavy slow-speed engine, I have always been answered that their use would be quite out of the question, because although they may perform satisfactorily on land, they could not possibly face the hardships of a seafaring life. I am told that a marine engine is required to run year in and year out at its maximum power, and that, unlike the conditions of land service, it has to be capable of running on insecure foundations with doubtful alignment. To these criticisms I would reply that, compared with many of the services in which the small high-speed engine is already employed, that of ship propulsion would appear to be relatively easy, the more so since the speed will be nearly constant and overloading non-existent.

RELIABILITY.

One is told that the first essential of any form of marine propulsion is absolute reliability. As a frequent passenger on ships, I can but agree wholeheartedly. Many factors must be combined to achieve reliability, of which the most important are prolonged experience and meticulous attention to detail design, but even so no prime mover made by man can ever hope to be 100 per cent. reliable. We must face always the possibility, however remote, of a serious breakdown, and security can be found only in numbers. With two or three engines, security is increased enormously, and when the number of engines runs far into double figures, as I am suggesting, security is virtually infinite, however frail the individual units may be. Although marine engineers may be justly proud of the reliability of the modern marine engine, yet no patient in a sick room ever received such devoted care ; day and night it is tended, coddled, and dosed, its temperature taken and its pulse felt by relays of doctors and nurses. I am going to suggest the other extreme, that the high-speed engines should be placed in cells, padlocked, and the keys left ashore. Should an engine break down on the voyage, a chalk mark on the door of its cell will suffice for the time being, and the inquest will be postponed till the ship returns to its home port, when any engine casualties, as well as those due for overhaul, will be removed bodily and exchanged for reconditioned ones. The removal and replacement of perhaps twenty such engines could be done in a few hours only, and the ship need never be out of commission due to engine trouble.

The most important, and also the most difficult, problem we shall have to deal with will be that of the transmission of power from a large number of mechanically independent units to a single propeller shaft. I say "mechanically independent" because it is, I fear, quite out of the question to contemplate gearing a large number of units to a single shaft ; the objections to this are, I think, fairly obvious. In the first place, it would involve stringing the engines out along the propeller shaft. In the second place, it leaves the reversing problem in the air, or at least, involves it in intolerable complication. Thirdly, unless some elaborate system of automatic clutches be provided, the independence of the units, and therefore the reliability of the power plant will be weakened. We are left, then, with some form of fluid transmission, either oil, air, or electricity, and of these electricity appears to be the most practicable one.

TYPE OF ENGINE.

The type of engine I would propose for such a purpose is that which has now been developed for heavy road vehicles. There is no reason in the world why, when the production of such engines has increased sufficiently, the first cost should not fall to below £2, and, in fact, almost reach parity with the petrol engine, which is now down to about 25s. per horse-power. I would advocate this type because it has attained a far higher degree of mechanical perfection than any other ; moreover, in regard to most of its running parts, it has now become largely standardised, so that replacements are already very inexpensive. It would require modification in certain respects, but no modification, I would insist, which would affect any of its well-tried moving parts.

The output of such engines ranges up to 150 H.P. at 2000 r.p.m. or rather more ; operated at, say, 1600 r.p.m., they would each develop 100 H.P. at a very comfortable load factor and with good economy. Such engines, however, are burdened with a great deal of auxiliary mechanism essential for road service. This adds considerably to their cost and could well be dispensed with. There are, for example, a lighting dynamo, a fuel supply pump, a water circulating pump, and lubricating oil pumps, none of which would be required. All this commissariat work could be catered for much more efficiently, and much more economically, by a centralised service. The cost of all this auxiliary gear, and still more the mechanism for driving it, forms a considerable item, and its elimination will reduce substantially the already low initial cost of each generating engine. The only auxiliaries we shall need to retain on each engine are the fuel injection pump, governor, and perhaps the electric starting motor. I think it will be found, even at this present early stage, that there are many manufacturers of commercial vehicle engines who would gladly accept £3 per horse-power for a bulk order for such engines. Each engine would be coupled to an electric generator which would be bolted direct to the fly-wheel housing, thus forming a self-aligning unit.

Let us now consider the case of a relatively large vessel requiring, say, 5000 actual shaft horse-power for propulsion and, say, 1000 H.P. for auxiliary and hotel services. For such a vessel I would advocate installing a total of seventy-five high-speed Diesel-electric generating sets, each of about 100 H.P. when running at 1600 r.p.m. Allowing for a 14 per cent. loss in the electric transmission (which I think is an outside figure), we shall need a total of fifty seven generating sets for propulsion, ten identically similar sets for auxiliary services, and, if the ship is going to be very long away from a home port, it may be advisable to carry, perhaps, eight more as spares, giving a total of seventy-five sets all identical and interchangeable. The overall dimensions of each set —Fig. 1—will be approximately 6ft. 6in. long, 2ft. 6in. wide, and 3ft. 6in. high ; each will weigh slightly under $1\frac{1}{2}$ tons. Since each generating set comprises a six-cylinder engine with extremely light moving parts and balanced both as to its primary and secondary disturbing forces, no foundation will be required, but, in order to eliminate entirely any trace of third order vibrations or torque reaction, I would suggest that each set be insulated from the ship's structure by the introduction of a resilient but well-damped mounting, such as is now customary in the case of motor car engines. I would suggest that the engines be placed in rows and in several tiers, one above the other—Fig. 2. So far as their operation and mounting is concerned, their position in the ship is immaterial, but for the sake of the wiring and pipe work, it will, of course, be convenient to group them together as closely as possible. It is also an essential part of the scheme that they shall be so placed that they can readily be slid and lifted out of the ship by a deck hoist. For reasons which I will explain later, each generating set, or possibly each pair of generating sets, will be enclosed in a box whose capacity will be approximately 60 cubic feet. The entire power-generating plant, both propelling and auxiliary, together with eight reserve sets, will be represented in effect by about 110 tons of rectangular packing cases, each of 60 cubic feet capacity, which may be stowed wherever convenient, having regard to accessibility, to unloading, and to pipe work—clearly a very small bulk and weight as compared with the usual power-generating plant. The supply of cooling water, of lubricating oil, and of fuel oil, will be served out to each set from a central distributing system, with pumps in duplicate, or even triplicate, in order to ensure absolute reliability. Each generating set will have its own electric starter operated from a push-button on the bridge, and this is a point which I wish to emphasise; once up to speed, it will immediately and automatically cut into the circuit and run always at a constant speed and constant load. Except for the speed governor, there will be no engine control whatever. Each propelling set will either run at the full capacity of its fuel injection pump, or not at all, and the ship's speed will be varied primarily by cutting in or out more or less of the generating sets, not by varying the load on individual sets. I am no electrician, and the advice I have gleaned from electrical engineers with whom I have discussed the problem, has been so diversified and so contradictory that I am little the wiser for it; but I cannot think there will be any insuperable difficulty in coping with the switchgear, whether the armatures of the generators are coupled in series or in parallel. There are, I appreciate, a dozen different ways of linking up the individual sets electrically, involving alternating current in combination with rectifiers, or direct current, with the generating sets either in series or in parallel, each apparently has its attendant advantages and disadvantages. But whichever method be adopted, I would insist that the complete independence of the generating sets should be maintained, and that each should be free to cut automatically into the circuit, so soon as the engine has built up speed and voltage, and to cut out as soon as there is any reverse flow of current. Such switchgear as is required should be restricted almost entirely to the propelling motors.

---

* Excerpts from the sixth Thomas Lowe Gray Lecture, Inst. of Mech. E., December 1st, 1933.

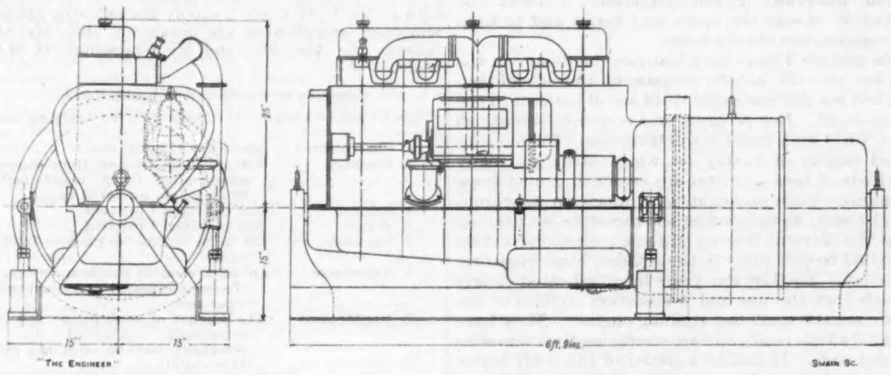

Fig. 1—Typical High-Speed Oil Engine Generator for Marine Service

Such, briefly, is the picture before my eyes of a future engine-room on shipboard—just stacks of wooden crates with occasional gangways between. It is not a romantic picture, very different, indeed, from the imposing scene of a ship's engine-room of twenty years ago. Sir Charles Parsons has already robbed the steam plant of most of its dignity, and I am proposing to substitute sheer impudence.

So much for the general scheme. I would like now to go into a little more detail and to forestall, as far as I am able, the criticisms which will be levelled at it, the first of which will, no doubt, be the cost of maintenance. A large fund of experience is now available as to the maintenance of these small high-speed engines in road service. This is a much more arduous service in almost all respects, in that the engines are required to run normally at much higher speeds than I have suggested, namely, 2000–2200 r.p.m., as against the 1600 r.p.m. I am proposing; they are constantly being started and stopped, constantly being overloaded till they are brought almost to a standstill, and are often left for long periods running idle and cold. These are hardships from which they will be free on the sea. In such engines, the principal wearing parts are the cylinder liners, the piston rings (more particularly the oil scraper rings), and the big-end bearings; other wear is trivial. The rate of wear per hour as actually measured in these small high-speed engines is no greater than in the large-slow-running types. But, in consequence of their smaller size, less wear can be tolerated; renewals must, therefore, be more frequent, but much less expensive. On balance, it will, I am satisfied, be found that the cost of renewals is far less than that of the large, slow-running engine, while the ship need never be out of commission owing to the necessity for repairs or renewals to the power-producing plant.

In the ship I am picturing there will be a total of seventy-five engines, but not much more than half this number in operation will suffice for ordinary cruising speeds and for dealing with the auxiliary services. If the ship is at sea for 4000 hours a year, then each engine will, on the average, be in operation for 2000 hours per year only. I would suggest that, after this period, it be removed for a top overhaul in a properly organised shop, where, as a matter of routine, it will be decarbonised, the oil scraper rings and valve springs renewed, the valves ground in, valve tappets and injectors adjusted, and the fuel injection pumps recalibrated. After the next 2000 hours the piston rings should be renewed, but not till after 8000 hours, or four years, should anything in the nature of an extensive overhaul be required, when the crank shafts will require regrinding, the cylinders relining, and new pistons, valves, &c., should be fitted. The cost of renewals at this stage will amount to perhaps 15 per cent. of the cost of a new engine, and the entire cost of reconditioning, including fitting, testing, &c., if made a matter of regular and well-organised routine, may amount to from £50 to £60 per engine. Allowing, therefore, for three top overhauls to one major overhaul, the cost of routine repairs and maintenance should average from £100 to £120 per engine in four years, or, say, £25 to £30 per annum. To this must be added perhaps an additional 30 per cent. to cover the hazards of accidental breakdown, making a total of about £2500 to £3000 per annum for all engine repairs and maintenance in a ship of about 10,000 tons, in which the total installed horse-power is 7500, the actual shaft horse-power at full speed 5000, and whose sea-going average is 4000 hours, or, say, 60,000 miles per annum. Not a very high figure, I think more especially when consideration is given to the fact that throughout its whole life the ship will never be out of commission for one minute for engine repairs, and that the routine overhauls will maintain all the engines in new condition and at maximum efficiency until obsolescence, not age or wear and tear, brings their lives to a close. In this connection I would mention that some of the manufacturers of high-speed Diesel engines for road vehicles are already undertaking the entire maintenance of their engines, including replacement with new engines when necessary, and including also the maintenance of all the engine auxiliaries, of the entire electrical equipment and batteries, at little more than the rate I have mentioned. As to the maintenance cost of the electrical gear, I am not, I am afraid, in a position to offer any figures, but since no batteries are involved, it is reasonable to suppose that it will be relatively very small.

As regards the details of the engine installation, I have mentioned already that the whole of the engine commissariat service should be dealt with as a centralised system. I think it is quite essential on account of the high temperature at which the engines should be run that they shall be cooled by fresh water, which will be kept flowing in a closed circuit through the water jackets of all the engines, whether they are running or not. By so doing all the engines will be kept warm, which will relieve greatly the work on the electric starters and obviate the heavy cylinder liner wear during the warming up process. The cooling water will be passed through a thermostatically controlled heat interchanger with the object of maintaining its temperature between 80 deg. and 90 deg. Cent. Outward and return circulating pipes will pass every engine cell, and it will be necessary merely to couple up the inlet and outlet connections of each engine. The sumps of all engines will drain by gravity into a hot oil tank. From this tank the lubricating oil will pass first through a centrifugal cleaner, then through an oil cooler to reduce the temperature to, say, 60 deg. Cent. From the oil cooler it will be pumped to a tank placed at a sufficient height to maintain a head equal to the normal pressure required for forced lubrication, namely, about 10 lb. to 12 lb. per square inch. From this tank there will lead a lubricating ring main to which each engine will be coupled. In this case I would suggest that the circulation of oil through each engine should take place only while the engine is running, and to this end a valve should be fitted interconnected with each starter, so that no engine can be started until its oil circulation is open. By this means each engine will be fed under pressure with a continuous supply of clean warm oil, and the danger of getting under load before the oil has warmed sufficiently to circulate freely will thus be avoided, for every engine will start with hot water in the jackets and warm oil in its bearings. Within the engine itself the lubrication system will be exactly as in a road vehicle engine, that is to say, all bearings will be fed by pressure in the usual manner, with the usual large-diameter drilled passages in place of oil piping, wherever possible. Each engine of 100 H.P. will require approximately 3 gallons per minute for the dual purpose of cooling and lubricating the bearings, so that the capacity of the oil circulating system should be about 200 gallons per minute. The fuel system should be similar to that of the lubricating oil, except of course, that no cooler is required. In order to ensure against gassing or air locks in the fuel pumps it is always preferable to maintain a continuous flow through them; but, of course, quite a low velocity will suffice. As in the case of the lubricating oil, the circulation of fuel to each individual engine will be interconnected with the starting of the engine. In like manner both the air intake and exhaust from each engine should be connected to ring mains, the latter, of course, water cooled. With such a system it may well be worth while to apply a supercharge and so raise the whole power of the plant by about 20 per cent., since this could be accomplished so easily by a single large centrifugal blower. The whole of the engine commissariat system will, of course, be operated electrically, and all vital or vulnerable parts should be in duplicate. The total power consumption of the engine auxiliary services, if in duplicate, will amount to somewhere about 50 H.P., or about 1 per cent. of the shaft horse power, excluding supercharging.

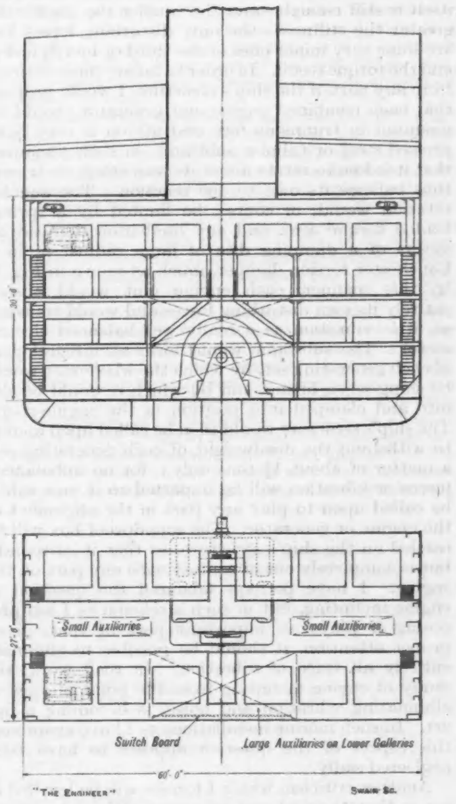

Fig. 2—Arrangement of Power Units in Ship

Although I have reckoned on a normal maximum shaft horse-power of 5000 with ten engines engaged upon auxiliary services, and eight in reserve, it is probable that in most services four or five engines will suffice for the auxiliary work when at sea, so that as many as seventy engines could at times be pressed into the work of propulsion, giving a normal shaft horse-power of 6000. If supercharged to increase the output by 20 per cent. and setting aside the use of two engines to drive the blowers, a maximum of just over 7000 shaft horse-power could be attained in emergency with all generating units in operation and supercharged.

Noise.

In order to cope with the noise difficulty, and at the same time to discourage any meddling with the engines by those on board, I would propose that each generating set or pair of generating sets should be enclosed entirely in a double-walled wooden soundproof box, well ventilated by connection to deck ventilators, or even a false funnel. This box will rest on the ship's structure entirely out of contact with the engine or its mounting. A glass window should be provided in each box through which an occasional visitor to the engine-room can see the commutator of the generator, a thermometer on the exhaust pipe, possibly, though not necessarily, an ammeter, and the crank case air vent. The amount of smoke from the latter will reveal the general condition of the piston rings and indicate when the time is drawing near for a top overhaul. Thus enclosed, the generating sets will sound like bees on a summer's afternoon, and the solitary engine-room clerk will be able to smoke his pipe of peace. Since the fuel injection pumps will have been calibrated ashore and set to give a maximum delivery sufficient for 100 H.P. only, at 1600 r.p.m., there can be no possibility of overloading, and I would insist that any adjustment to the fuel pumps or governors be sealed, lest some engineer cracksman succeeds in breaking and entering the engine's cell. All engines should, I suggest, be started and stopped by means of a remote control, either from the main switchboard or the bridge. Lights on the switchboard and in each engine cell will indicate which engines are in operation at any moment. The engine-room clerk will be expected to keep records of the number of hours run by each generating set, of the total fuel and oil consumption, and it will be his business also to take an occasional stroll round and to chalk mark for the benefit of the engineer ashore, any set which is persistently showing an exhaust temperature much above the average or which is showing excessive fuming from the crank case breather.

VIBRATION.

In a six-cylinder engine all primary and secondary disturbing forces are balanced completely, except in so far as the internal stresses they exert on the structure are concerned. Provided the engine structure itself is stiff enough—and the smaller the engine the greater the stiffness—the only disturbing forces left are some very minor ones of the third or fourth order, and the torque recoil. In order to isolate these entirely from any part of the ship's structure, I would propose that each combined engine and generator should be mounted in trunnions fore and aft on a very light pressed steel or tubular subframe, in such a manner that it is free to rotate about its own crank shaft, and thus balance its own torque reaction. The augular rotation would, of course, be limited by a spring-loaded torque arm, and any oscillation damped by means of a damping disc of large radius, as in a Lanchester torsion damper, much as shown in Fig. 1. In this manner, each engine unit would absorb entirely its own disturbing forces and would transmit as little vibration as a really well-balanced electric motor. The subframe would form an integral part of each generating set, by which the whole unit would be slung when lifting, and by which it would be slid into and clamped into position in the engine-room. The ship's structure would then be called upon merely to withstand the deadweight of each generating set, a matter of about 1½ tons only; for no unbalanced forces or vibration will be imparted to it, nor will it be called upon to play any part in the alignment of the engine or generator. The soundproof box will be carried on the ship's structure, so that it surrounds, but is completely out of contact with any part of, the engine. I have perhaps laboured the question of engine mounting, but in such a scheme as I am proposing it plays an important part in that, given proper attention, it should be possible to eliminate entirely all trace of vibration. In road work, the study of engine mounting from the point of view of eliminating vibration and noise, is becoming a fine art. In such marine installations as I have examined, this aspect of the question appears to have been neglected sadly.

Another criticism which I foresee will be levelled at me is that the fuel and oil consumption of such an equipment will be excessive. If this is so, of course, the scheme will lose much of its charm, but I think I can show that it will not be appreciably, if any, higher than that of a direct-driving Diesel plant. In the first place, thanks to their high speed, their light moving parts, and perfect alignment which ensures low internal friction, the specific fuel consumption of these small engines is at least as good as, and usually even better than, that of the large slow-running type. The efficiency of the Diesel engine gains nothing with size, and small six-cylinder engines of about 100 H.P. can maintain a fuel consumption of well under 0·4 lb. per B.H.P.-hour over a wide range of load or speed, and over very long periods. The Gardner commercial vehicle engine, to take a good example, has in ordinary every-day service a fuel consumption of only 0·37 lb. per B.H.P.-hour, when driving the whole of its auxiliary mechanism, and even better results than this can and would be obtained under the very favourable running conditions I am providing for. What large slow-speed engine can better this? After 2000 hours without a top overhaul, the consumption will have increased from 0·37 lb. to about 0·39 lb. per B.H.P.-hour, so that we may take the mean average as 0·38 lb. I have suggested that the mean overall efficiency of the electric transmission will be 86 per cent. at cruising speeds, which will give a fuel consumption of 0·442 lb. per actual shaft horse-power-hour, a figure only slightly inferior to that of the slow-speed type. Although the lowest consumption, in terms of shaft horse-power, of my multiple-engine proposal may not be quite so low as that of the large direct driving plant under favourable conditions of speed, yet in my proposal this same consumption will hold good for all speeds from dead slow to full speed (excepting only in so far as the efficiency of the propelling motors will vary slightly with speed). So far as the generating sets are concerned, the consumption per kilowatt-hour will be entirely unaffected by any variation of load from less than 2 per cent. upwards. With regard to lubricating oil consumption, this ranges from $^1/_{300}$ lb. per H.P.-hour, when the oil scraper rings are new, to about $^1/_{150}$ lb. per H.P.-hour after 2000 hours, say, an average of $^1/_{20}$ gallon per hour for each generating set. Under the operating conditions I have envisaged the very cheapest lubricant procurable will be all that is needed. If we take 4000 S.H.P. as the normal cruising condition, then the fuel and oil consumption of the propelling engines will be approximately 14 tons and 50 gallons per day respectively.

I have stressed the argument that all engine repairs and overhauls should be carried out ashore in a properly organised and equipped maintenance shop, where, since all engines are identical and all parts interchangeable, the work can be undertaken as a continuous routine. There is no reason, however, why the repairs and maintenance should not be carried out on board, for the staff and equipment needed are extremely small. Where a ship is leading a purely vagabond existence this may be necessary; but in the case of ships which visit their home ports at regular intervals, it will—obviously, I think—be preferable to save the space and hands and to keep the maintenance shop ashore.

The picture I have sketched may be dreary in the extreme—it will be the despair of the school-boy, who will not get one single thrill out of his visit to the engine-room. But progress and economic conditions must, I feel sure, trend in this direction. The monster Diesel engine of to-day on whose structure many hundreds of tons of metal are lavished, cannot hope to endure. Such an engine is as much an anachronism, I think, as the prehistoric monsters we gaze up at in the Natural History Museum, which have long since had to give place to the smaller, lither creatures of to-day. The last few years have indicated clearly enough that the internal combustion engines of the future are the small fast-running engines. They have invaded all the roads, and are stretching their tentacles far and wide. It can be a matter of time only before they invade our shipping also The time has now arrived, I think, when the marine engineer should consider seriously how he will deal with their accommodation, their catering and their hygiene, lest they swarm upon him unawares and overwhelm him.

Liquid Fuels from Coal for Naval Purposes.*

By Eng.-Capt. S. H. DUNLOP, R.N.

THE importance to this country of being independent of external sources of supply for liquid fuel for the Navy is apparent to everybody, and the subject has naturally attracted a considerable amount of public interest. Unfortunately, many extravagant and unsubstantiated claims have been made by the various rival interests which have given rise to a good deal of controversy and doubt. It is proposed, however, to keep this paper as far as possible beyond the realms of controversy, and to confine it to an account of the experiments and trials carried out in H.M. Naval Service with liquid fuels produced from coal, together with an explanation of the Admiralty requirements in connection with such fuels.

So far as can be traced at present, the Admiralty first turned its attention to the combustion of coal distillates in 1867–1870, when Captain Selwyn carried out some experiments in burning creosote in marine boilers at Woolwich Dockyard. At that time creosote was a waste product from the distillation of tar for chemical purposes, and it appears that the matter was allowed to lapse owing to the limited supplies of fuels possessing the qualities then considered necessary. From 1898 onwards continuous experiments in burning oil fuel were carried out in H.M. ships, and in 1912 it was decided that the boilers of all new surface warships should be fitted for burning oil fuel only. This increased dependence upon imported fuels naturally revived the interest in home-produced fuels, and any developments giving promise in this direction have been encouraged by the Admiralty to the utmost extent.

The most obvious and accessible sources of such fuels were, of course, the considerable shale deposits of this country, which have now been either actively worked or explored for many years. These include the Kimmeridge shale beds in Dorset and other beds in Norfolk, the utilisation of which has been frequently suggested, but attempts in this direction have been abandoned owing to the high percentage of sulphur; also the shale deposits of Scotland which have been worked for many years, and from which many thousands of tons of oil have been extracted and used to our great content during the war and earlier periods. Owing to competition with imported oils, the production of shale oil as a boiler fuel is no longer economically possible.

CREOSOTE PRODUCED BY THE HIGH-TEMPERATURE DISTILLATION OF COAL.

The possibility of using creosote for admixture with petroleum oil fuels was considered in the early stages of the introduction of oil fuel burning in the Navy, but prior to 1913 it was the practice to specify that the creosote must be cooled to some low temperature in order that all naphthalene present in it, which would be thrown out of solution at this temperature, should be removed before the residual oil was used in an oil fuel installation. It was required also that all naphthalene which would solidify at, say, 32 deg. Fah., should be removed before the admixture with ordinary petroleum oil fuels, as it was feared that in the course of using such mixtures solid naphthalene might separate out in the tanks and pipes. In 1913 the Admiralty chemist found that it was not necessary to remove from creosote the naphthalene which would solidify at temperatures down to 32 deg. Fah. before mixing it with petroleum oil fuels, provided the resultant mixture did not contain more than 7 to 8 per cent. of naphthalene. In fact, he found that the presence of up to 7 or 8 per cent. of naphthalene had a beneficial effect on a mixture of creosote with a thick petroleum fuel oil, as it caused the mixed oil to be less viscous than the original petroleum fuel oil.

As a result of this discovery, practically half a million tons of creosote was purchased by the Admiralty during and just after the war for admixture with petroleum fuel oils, in order to augment our supplies of liquid fuel. This creosote contained approximately 18 per cent. of naphthalene, and the mixtures were so arranged that the resultant naphthalene content did not exceed 7 per cent. For some years after this, no purchases of creosote were made, but in 1929 owing to the failure of the American market for this product, large quantities became available, and in order to assist the trade the Admiralty obtained 10,000 tons of creosote which was mixed with twice its bulk of Trinidad oil fuel and issued to the Fleet. It was burned satisfactorily, and no insurmountable difficulties were experienced. In 1931, on being approached by the interests concerned, the Admiralty agreed to consider the purchase of further quantities of creosote, and with a view to facilitating supply the following amended temporary specification was drawn up, after discussion between the Admiralty and the representatives of the trade:—

Admiralty Specification for Creosote Fuel Oil.

The oil will be required to comply with the following specification:—

1. Flash point .. Not below 172 deg. Fah.
2. Viscosity .. The oil shall be free from separated solids after being maintained at 60 deg. Fah. for seven days.
3. Sulphur .. .. Not to exceed 1 per cent.
4. Water .. .. Not to exceed 1 per cent.
5. Tar acids .. Oil to be as free as possible from tar acids.
6. Anthracene .. Oil to be sensibly free from anthracene. (To be interpreted as a maximum of 1 per cent.).
7. Naphthalene.. The amount of naphthalene and other compounds estimated by the Admiralty method must not exceed 24 per cent.
8. Pitch .. .. Not to exceed 2 per cent.
9. Oil to be free from sediment or other impurities likely to choke the burners.
10. Oil to be practically free from inorganic acidity.

Owing to the financial crisis, the negotiations for the purchase of this fuel had, however, to be abandoned, and no further supplies have been obtained from this source. Relaxations in the producers' favour, as compared with previous specifications, are embodied in clauses 2 and 7. In clause 2 the temperature specified for the test was raised from 32 deg. to 60 deg. Fah., and this admits oils of a quality which would necessitate continuous heating from the collecting point till mixed in the storage tanks with the proper proportion of petroleum oil fuel. The limiting percentage of naphthalene permitted by clause 7 would require mixing the creosote with about three times its amount of a petroleum oil. These relaxations add very considerably to the cost of collection, transport, storage, and supply, and involve some loss of flexibility in the arrangements at naval fuelling depôts. It should be remarked that the presence of more than a very small proportion of anthracene has, according to information at present available, a harmful effect on the *personnel* handling the oil; further, tests have shown that if more than 0·25 per cent. of it is present in a mixture with petroleum fuel oil, anthracene paste is liable to be deposited.

The pitch determined as a residue on distillation is limited to a maximum of 2 per cent., as a higher content has been found to cause trouble by precipitation when mixed with petroleum oils.

The calorific value of the creosote supplied to the Admiralty was from about 16,000 to 17,000 B.Th.U. per lb.

FUEL OIL PRODUCED BY THE LOW-TEMPERATURE CARBONISATION OF COAL.

In 1912 the problem of developing home sources of supply of fuel for the Navy was examined exhaustively by a Royal Commission, of which Lord Fisher was Chairman and Dr. G. T. Beilby (later Sir George Beilby) one of the members. Amongst other things, Dr. Beilby made a report to the Commission on "The possibility of a development of a new carbonising industry founded on the distillation of bituminous coal at a temperature much below that used in gas retorts and coke ovens." The data mainly used in the report were obtained from experimental work on a small industrial scale carried out in Glasgow under the direction of Dr. Beilby. As a result of his experiments, Dr. Beilby was able to show—and what he found largely holds good to this day—that by weight from 5 to 8 per cent. only of the coal carbonised could be obtained as a fuel oil, and that the really big problem was not so much the production of the fuel as the disposal of the coke, which amounted to from 65 to 75 per cent. of the original coal. However, the war intervened and the work was temporarily suspended.

When the Fuel Research Station at Greenwich was built and put into operation at the close of the war, with Sir George Beilby as Director, work on low-temperature carbonisation was revived on a larger scale, mainly with a view to the production of a smokeless domestic fuel, and it has been pursued actively on an experimental scale ever since. Concurrently, the production of smokeless semi-coke, with fuel oil as a by-product, was taken up by quite a number of commercial concerns, although it was not till about 1927 that fuel oils whose properties approximated to Admiralty requirements were offered for test and trial from such sources.

---

* The Institution of Engineers and Shipbuilders in Scotland, November 7th, 1933.

Before proceeding with the narrative of events, it is proposed to digress somewhat and give a brief account of some of the products of the process of low-temperature carbonisation of coal. As a preliminary, the following extract from the report of the Fuel Research Board for the period ending December 31st, 1924, will probably be of interest, as showing the distinction between low and high-temperature carbonisation of coal :—

"By low-temperature carbonisation is understood the destructive distillation of coal at temperatures in the region of 600 deg. Cent., instead of at the higher temperatures used in the gas and coke oven industries. At the higher temperature more of the coal is converted into gas and less into tar and coke, while from suitable coal a stronger coke is left behind; incidentally, the yield of ammonia is also much greater. At the lower temperatures enough combustible volatiles are retained in the coke to make it catch fire and burn readily, though not enough to generate smoke; larger quantities of tar are collected without being decomposed into gas, while from the gas itself as well as from the tar some light spirit can be extracted and converted into motor spirit. Low-temperature carbonisation accordingly offers a possible, and probably the only possible, means of treating coal so as to obtain a source of oil fuel and motor spirit, together with a smokeless fuel that can be burned on any domestic grate."

By the application of low-temperature carbonisation to 1 ton of bituminous coal, there is produced approximately 14 cwt. of semi-coke, from 16 to 20 gallons of coal tar, from 2½ to 3 gallons of motor spirit, and 4000 cubic feet of gas. By distilling the coal tar a fuel oil which will meet Admiralty requirements can be produced, and the amount of the oil varies from 35 to 50 per cent. of the coal tar, according as the tar acids are removed from the fuel or not. In other words, the amount of suitable fuel oil produced per ton of coal is from 5 to 8 gallons, or from 2·5 to 3·5 per cent. by weight. By treating cannel coal, the tar yield can be increased to about 50 gallons per ton, but such coal, although plentiful in the aggregate, is distributed in comparatively small patches in the United Kingdom, and mining difficulties render it unsuitable as a potential source of home-produced oil fuel in an emergency.

At the beginning of 1927 the Fuel Research Station supplied a small quantity of fuel oil to the Admiralty Engineering Laboratory at West Drayton for examination of its behaviour in a compression ignition engine of the submarine type. After slight modifications to the atomising arrangements, satisfactory running was obtained at full power with a reasonable fuel consumption using normal blast pressure. In November, 1928, 10 tons of oil fuel prepared by the Fuel Research Station was sent to the Admiralty Fuel Experiment Station at Haslar for burning under boilers of the naval type. The Admiralty Chemist's report on the chemical properties of the oil as received at Haslar was as follows :—

Specific gravity at 60 deg. Fah. ..	1·004
Flash point, deg. Fah.	165
Viscosity, Redwood II., at 60 deg. Fah., secs.	12
Viscosity, Redwood II., at 32 deg. Fah., secs.	53
Setting point, deg. Fah.	Below 20
Free mineral acidity	Nil
Sulphur, per cent.	0·69
Water, per cent.	2
Appearance	Brownish black opaque
Sediment, per cent.	Below 0·005
Odour	Coal tar
Crude tar acids, per cent.	34·7
Naphthalene	Nil
Anthracene, per cent.	0·4
Calorific value, B.Th.U. per lb. ..	16,380

A small quantity of this oil was burned in a 900 lb. per hour sprayer, but it was not found practicable to burn the oil without pulsations. The oil was then heated, in contact with water, to 190 deg. Fah., and allowed to settle overnight. The fuel oil was drained off from the surface, and it was found that the water content had been reduced from 2 to 0·7 per cent. The treated oil burned quite satisfactorily under the boilers at Haslar, and in a subsequent trial in H.M.S. "Tyrant," without pulsations. The boiler efficiency obtained was as high as that when using Texas oil. Mixtures of the coal oil fuel with equal proportions of Texas, Burma, Borneo, Persian, and Trinidad petroleum oil fuels showed no signs of separation or solid deposits after standing for ten weeks. The medical officer who attended the trials in H.M.S. "Tyrant" reported that no discomfort was experienced from the fumes, and air samples taken and tested were satisfactory.

As a result of these trials the Admiralty prepared a tentative specification and forwarded it to all known concerns producing oil from coal by low-temperature carbonisation. They were asked to state whether they would be prepared to forward small samples of the oil for preliminary tests by the Admiralty Chemist and at the Admiralty Fuel Experimental Station, Haslar. The specification since then has been slightly revised, and is now as follows :—

1. The flash point shall not be lower than 175 deg. Fah. (Pensky-Marten).
2. The proportion of sulphur contained in the oil shall not exceed 1 per cent.
3. The oil shall be free from inorganic acidity and sensibly free from anthracene and sediment.
4. The crude tar acids shall not exceed 36 per cent.
5. The quantity of water delivered with the oil shall not exceed 0·5 per cent.
6. The viscosity of the oil shall not exceed 1000 secs. at a temperature of 32 deg. Fah., as determined by Redwood's standard viscometer pattern II., Admiralty type, for testing fuel oil.
7. The pitch shall not exceed 2 per cent.
8. Solids separating out after maintaining the oil at a temperature of 32 deg. Fah. for seven days shall not exceed 0·1 per cent.
9. The oils shall be free from earthy carbonaceous or fibrous matter or other impurities likely to choke the burners.

In all, twenty-five concerns were communicated with, and fourteen forwarded samples for preliminary tests. Six of these firms sent samples which approximated to the Admiralty requirements sufficiently closely to justify placing orders with them for 20-ton lots for actual burning tests at Haslar and in H.M.S. "Tyrant." The trials of these fuels were carried out in 1930 and 1931, and in general were quite satisfactory. In one fuel a quantity of wax of a hydro-carbon type was found on the surface when the oil was delivered, and in another there was an excess of water, but on the whole the 20-ton lots conformed quite well to the samples. Exhaustive mixing trials were carried out with these oils and various petroleum oil fuels in ratios of 2 : 1, 1 : 1, 1 : 2, and also with the coal oils themselves. These trials showed that the mixtures remained quite stable, and no objectionable deposits were found to separate out, provided the pitch content of the coal oil was kept under about 2 per cent. The Admiralty Chemist's report on a typical fuel supplied for these trials was as follows :—

Specific gravity at 60 deg. Fah. ..	1·01
Flash point (Pensky-Marten), deg. Fah.	186
Viscosity, Redwood II., at 60 deg. Fah., secs.	9
Viscosity, Redwood II., at 32 deg. Fah., secs.	25
Sulphur, per cent.	0·73
Water (by volume), per cent. ..	1·12
Mineral acidity	Nil
Appearance	Dark brown, transparent
Sediment (total insoluble in benzene), per cent.	0·046
Naphthalene, per cent.	2·4
Anthracene	Trace
Pitch, per cent.	2·2
Crude tar acids, per cent.	27
Ash, per cent...	0·03
Calorific value, B.Th.U. per lb. ..	16,930

Ultimate Analysis.

	Per cent.
Carbon	81·17
Hydrogen	8·79
Nitrogen..	0·83
Sulphur	0·73
Oxygen	7·33
Water	1·12
Ash	0·03

A report of an evaporation trial of this fuel and of a similar trial of Texas fuel oil for comparison will be found in the Appendix.

During 1932, after a preliminary trial at Haslar, the Admiralty purchased 350 tons of a low-temperature carbonisation fuel oil from which the tar acids had been extracted. According to information received from the Fuel Research Station, the tar acids in a fuel reduce the calorific value by an average amount of about 35 B.Th.U. per lb. per 1 per cent. of tar acids. Consequently, the calorific value of the fuel purchased was considerably higher than that of those previously supplied, as will be seen from the following typical analysis :—

Specific gravity at 60 deg. Fah	0·970
Flash point (Pensky Marten), deg. Fah ..	178
Viscosity, Redwood II., at 60 deg. Fah., secs.	55
Viscosity, Redwood II., at 32 deg. Fah., secs.	130
Sulphur, per cent.	0·85
Water, per cent.	0·10
Inorganic acidity	Nil
Appearance	Brown, opaque
Sediment, per cent.	0·01
Naphthalene, per cent.	2·2
Anthracene	Trace
Pitch (residue on distillation), per cent. ..	2·1
Crude tar acids, per cent.	2·0
Spontaneous ignition temperature in oxygen, deg. Cent.	323
Calorific value, B.Th.U. per lb.	17,800

Ultimate Analysis.

	Per cent.
Carbon	87·07
Hydrogen	9·85
Oxygen	0·99
Sulphur	0·85

The oil was delivered to H.M. destroyer "Westminster," attached to the Home Fleet, and proved to be satisfactory on service, which included a run of two hours at full power. There were no unpleasant fumes given off, and the oil had no deleterious effect on the *personnel* handling it.

Early in the present year the Admiralty arranged to purchase small monthly amounts of this fuel for a year, amounting in the aggregate to 3000 tons in 1933. As the demand for tar acids for other requirements is limited, a portion of the deliveries of the fuel oil will be of a quality similar to that referred to above, the remainder being sensibly free from tar acids. Table I. gives a comparison of the calorific values taken on a weight and on a volume basis, and shows that the endurance of a ship is only slightly affected by the use of low-temperature carbonisation fuel oils.

Table I.

	Specific gravity.	Calorific value, B.Th.U. per lb.	Calorific value, B.Th.U. per gall.
Persian fuel oil	0·895	19,060	170,500
Trinidad fuel oil	0·955	18,810	179,600
Low-temperature carbonisation oils free from tar acids	0·966	17,830	172,250
Including tar acids	1·014	16,780	170,485

From the foregoing it will be seen that, although a fuel oil which is acceptable for naval purposes can be produced by the low-temperature carbonisation of coal, the supply is still very limited. So far as can be ascertained, out of some 35 million tons of coal used in this country for domestic purposes, at present approximately 220,000 tons per annum is treated by low-temperature carbonisation processes. From this amount of coal about 7000 tons of a fuel oil suitable for naval purposes could be produced. We have therefore a long way to go before the effect is likely to be appreciable upon even the annual peace-time requirements of the Navy.

HYDROGENATION.

During 1930 the Admiralty purchased a small quantity of fuel oil produced by the hydrogenation of coal, for trial at the Admiralty Engineering Laboratory in compression ignition engines of the submarine type. The oil was found to be quite suitable for use either in blast or solid injection engines, provided slight modifications were made to the spraying conditions. The oil had the following properties :

Specific gravity at 60 deg. Fah.	0·913
Flash point (closed), deg. Fah.	188
Viscosity, Redwood II., at 32 deg. Fah., secs.	56
Calorific value, B.Th.U. per lb.	18,600
Spontaneous ignition temperature in oxygen, deg. Cent.	288
Sulphur, per cent.	0·48
Ash, per cent...	0·01
Hard asphalt, per cent...	0·01
Soft asphalt, per cent.	0·01
Water	Nil
Acidity	Nil

When treated by hydrogenation 1 ton of bituminous coal free from ash and moisture is stated to yield about 175 gallons of petrol or fuel oil—that is, from 60 to 70 per cent. by weight—but, in addition, over 2 tons of coal, as mined, is required for steam raising, hydrogen production, &c. Thus, 1 ton of petrol or fuel oil can be produced by the expenditure of from 3½ to 4 tons of coal, which is a higher yield of liquid fuel per ton of coal than can be obtained by any other known process. There is, however, at present comparatively little difference in the cost of producing petrol, Diesel oil, or furnace oil, and production would therefore naturally be concentrated on the fuel fetching the highest price. To the Admiralty the process is at present of direct interest principally as a possible source of supply of fuel for submarines, and in the more distant future as a potential source of furnace oil. It is of further interest in encouraging home industries and thereby limiting to some extent the importation of what is now an essential commodity, thus relieving somewhat the Navy's burden in the event of war.

COAL-OIL FUEL.

In a paper* read before the Society of Chemical Industry, Professor Brame gives most of the information available on the subject. As he states, extensive experiments with coal-oil mixtures were carried out in the United States during the later years of the war by Lindon Bates and H. O'Neill, who were afforded considerable assistance by the United States Government. They used soap as a stabiliser and claimed that 1 per cent. of this substance retained from 30 to 40 per cent. of coal dust (95 per cent. of which passed through a 200-mesh sieve) in suspension for several months.

In the year 1918 the material was tried out in a small gunboat, U.S.S. "Gem," and the trials were witnessed by Admiralty representatives. Later, the Admiralty obtained a small quantity from America, and carried out a few burning trials at Haslar. The trials were abandoned, however, principally owing to doubts as to the stability of the mixture under service conditions where the possibility of access of water to the fuel cannot be ignored. Interest in the subject was revived last year by the publicity given to the successful trial of a coal-oil fuel in the Cunard liner "Scythia." It has been stated that the Cunard mixture does not contain a stabiliser and that the coal dust remained in suspension for many months without any appreciable deposit. It is possible that this fuel is applicable to certain ships of the mercantile marine specially adapted for the purpose, where the additional weight and space necessitated by its use and the low rates of burning can be accepted. It is unsuitable, however, as a fuel in modern warships, owing to the difficulties of transport and storage and to the accumulation of ash and soot in the boiler furnaces and on the external surfaces of the tubes when being burned at the high rates of forcing necessary in H.M. ships.

APPENDIX.

	Low-temperature carbonisation oil fuel.	Texas oil fuel.
Duration of trial, hours	2	3
Pressure of evaporation, lb. per sq. in.	220	220
Feed water temperature, deg. Fah. ..	80	72
Temperatures—		
Deck, deg. Fah.	64	58
Boiler-room, deg. Fah	87	89
Funnel, deg. Fah	711	708
Fuel—

South African Engineering Notes.

(By our South African Correspondent.)

Port Elizabeth's New Harbour.

Thousands of people from the Midland and Eastern Province areas thronged Port Elizabeth on Saturday, October 28th, to be present at the opening of the first quay of the new harbour. The ceremony was performed by the Minister of Railways and Harbours (Mr. O. Pirow), the first ship to tie up alongside the first deep-water berth ever constructed in Algoa Bay being the flagship of the African Squadron, H.M.S. "Dorsetshire." The new work, which was described in our issue of December 4th, 1931, is named the Malan Quay, or the No. 1 Quay, and has swallowed up the old north jetty and runs due east from the shore for 2000ft. It will provide berthage for four ships when completed. Beyond its end a rubble mole will extend for a further 1550ft. Should the trade of the port continue to expand, this mole will be converted into an extension of the quay. The Malan Quay is far from completed; in fact, three years, more work will be required, and at present even the berth now opened is totally unequipped. The construction will, however, have advanced sufficiently by the end of the year to permit steamers to berth at the wharf, but they will have to use their own derricks for loading and discharging for some months. The plans provide for completing the cranes, sheds, &c., by June of next year. The harbour scheme now being proceeded with at Port Elizabeth is planned to enclose an area of between 260 and 300 acres, and to provide berthage for eleven large steamers simultaneously, while, should traffic justify it in the future, additional wharfage could easily be provided without departure from the existing plan.

On the south and east sides the harbour is protected by the south breakwater—already completed—which is 4850ft. in length. The northern side is provided by the Malan Quay. Running parallel with this Quay from the shore, and providing 1250ft. of wharfage, will be No. 2 Quay. The work on this section, which lies 1000ft. south of the Malan Quay, and that much nearer to the breakwater, has just commenced. This will be the mail vessel wharf. Deep-water berthage at No. 2 Quay will be available within about three years from now. From a point in the breakwater, somewhere over half-way of its length, a mole will project towards the extremity of the Malan Quay, and with it form the dock entrance with a width of 800ft. This latter mole will be about 750ft. in length. With the completion of the harbour there will be safety within its boundaries. At present passengers embark in tugs to go ashore and return on board, and the south-east wind continually interferes with the handling of cargo. Probably at no other port in the world has so much cargo been landed and shipped under such impossible conditions. The lightermen of Algoa Bay deserve great credit for their skill, endurance, and speed have battled triumphantly for years with the huge drawbacks of Port Elizabeth as a cargo port. With steamers able to come alongside quays and be discharged by cranes a certain amount of cargo, which, on account of its weight, had to be discharged at East London or Durban, will be landed at Port Elizabeth, and probably cargo intended for Rhodesia and parts of the Union served by the railways from Port Elizabeth will be diverted from East London, Durban, Delagoa Bay, and Beira, but it is not likely that it will be of such proportions as to constitute serious losses to those ports.

The total cost of the present work in hand, excluding the cost of the breakwater and the contemplated mole from the breakwater, will be £1,413,420. When the port is completed the total expenditure will have been in the neighbourhood of £3,500,000. The original scheme, as planned at the beginning of the century, called for a breakwater following much the same line as the one built, but the northern section of the works would have started from the shore so much more to the north that the area of water enclosed would have been 900 acres. In 1913 a modified scheme to cost £8,000,000 was approved, and in 1919 a start was made with the south breakwater. In 1930 Mr. J. F. Craig, Senior Harbour Engineer of the Union, evolved the scheme of to-day, which was recognised as a practical scheme from the financial point of view, his plans ensuring a saving of £5,000,000. It is to Mr. Craig that Port Elizabeth owes the realisation of its long-deferred dream.

Alcohol as Motor Fuel.

A scheme which may make South Africa independent of outside supplies of motor fuel and which may, in addition, greatly reduce the cost of exporting refrigerated fruit, is expected shortly to be entered upon. Dr. Henry Arnstein, stated to be one of the foremost chemical engineers in the United States, has been engaged as a technical expert by a company out here, which is about to be registered for the manufacture of alcohol. South Africa produces more maize and sugar than it could consume, and it is with this surplus production that it is proposed to deal. The Union imports a large variety of chemical products used in the manufacture of such articles as toothpaste, shoes, dyes, pharmaceutical goods, textiles, paints, varnishes, and a host of others. Such chemicals could be manufactured in South Africa, but before that is possible a large volume of cheap alcohol is necessary; also, as there are no petroleum resources in the country, all motor fuel has to be imported. In South Africa it should be possible to produce fuel alcohol at exceedingly low cost.

New Rolling Stock.

One of a number of indications of improved industrial conditions in the Union of South Africa is furnished by the considerably increased activity in the railway workshops, particularly those at Durban, where practically all the staff is now working on a five-day basis, and the great majority of the artisans who were, for financial reasons, de-graded to the rank of labourers, have been reinstated to their former positions and rates of pay. The construction work in hand includes two hundred 50-ton high-sided coal wagons, and nine second-class main line corridor coaches, while authority is expected for a further thirteen main line coaches. An order for one hundred fruit wagons for use in the Western Province has recently been completed, and all the vehicles were in service early in July. The nine second-class coaches are required to replace some of those destroyed by a fire at the Salt River Works. They are due for completion in time to cope with the extra traffic always experienced at the end of the year, which, owing to the improvement in trade, will be much greater than in either of the past two or three years. The coal wagons are of an improved type designed by the Administration's own staff, having underframes with central box girders, giving increased strength without increased weight, and with bogie centres running in oil baths to ensure ample lubrication.

Electrical Work at Pretoria.

The first positive steps in connection with the development which is expected to follow in Pretoria on the production stage being reached at the works of the South African Iron and Steel Industrial Corporation at Pretoria West, are now to be taken. The Pretoria City Council proposes to take immediate action, and intends to apply to the Administrator for a loan of approximately £350,000, which is to be expended on extending the existing electricity supply scheme. When the first estimate of the electric power required by the Iron and Steel Corporation was made, it was calculated that the Pretoria Electricity Supply Department would have to provide only 3000 kilowatts per annum. Recently, the Iron and Steel Corporation informed the City Council that its needs would be 9000 kilowatts per annum. The existing plant is incapable of supplying this demand, and the City Council will have to spend £75,000 on the extension of mains, plus £275,000 on the purchase of new plant, which will include a 20,000-kilowatt turbine and new boilers.

Electrification of Main Line.

The electrification of the stretch of main line between Glencoe Junction and Vryheid (Natal) is to be begun as soon as the Harrismith-Ladysmith electrification scheme is completed. The cost will be roughly £300,000, and on the two lines it is expected to effect a saving of just under £70,000 per annum. At present the main line is electrified from Cate Ridge to Glencoe Junction, and continued electrification will therefore spread from there in the form of the letter V. The route mileage from Glencoe to Newcastle is a little over 37 miles, and from Glencoe to Vryheid 60 miles, giving a total of 97 miles. With the prospect of continuation to Newcastle and Vryheid, there will be a network of electrified lines in Natal covering 526 track miles, and altogether South Africa will still further advance its position as owner of the second largest electrified system in the world, and the largest in the Empire, its magnitude only exceeded by the United States' Chicago-Milwaukee electric system.

New Enterprises.

The Union Government has decided to proceed immediately with the construction of the largest irrigation scheme ever undertaken in South Africa. A sum of £4,000,000 is to be spent on the Vaal-Hartz scheme. This project, which will take five to six years to complete, will give employment to 3000 workers, and will result in over 120,000 acres of land being put under irrigation. The scheme entails the damming up of the Vaal River, and by means of a canal taking water through a neck into the Hartz River depression. A sheet of water about 90 square miles in extent will be produced. Paarl Municipality is embarking upon a sewage scheme to cost £140,000; Kroonstad is proceeding with a scheme for the reconstruction of its electric power system, which will comprise a new power station containing two three-phase alternators, each rated at 1250 kilowatts, together with steam-raising equipment and an economiser for 200 lb. per square inch at 600 deg. Fah.; Lydenburg is to spend £13,000 on a new water supply scheme. There is a great demand for electric cooking stoves, water heaters, and refrigerators. Cape Town is installing cookers at the average rate of 210 per month. In the Union and in Rhodesia there is a boom in wireless material; fully 50 per cent. of this business goes to American firms.

Pioneer of Steel Industry Dead.

The death occurred in Pretoria on October 23rd, of Mr. Cornelius Frederik Delfos, the only full-time director of the South African Iron and Steel Industrial Corporation, Ltd. Mr. Delfos was sixty-five years of age, and was perhaps the first man to visualise the great industrial undertaking which is now approaching completion at Pretoria West. Born in Amsterdam, Mr. Delfos was an engineer by profession. He came to South Africa forty-three years ago, and went straight to Pretoria, where he set up a small workshop with only one lathe. The enterprise grew and developed into the well-known concern, Delfos, Ltd. As early as 1906 Mr. Delfos conceived the idea of an iron and steel works at Pretoria, and spent many days on the hills overlooking the town prospecting for iron ores, coal, and limestone. His investigations convinced him of the success of such a project, both technically and economically. He was able to interest friends, who put in capital to put up an experimental plant close to the site of the works now being erected. This experimental works, the Pretoria Iron Mines, Ltd., worked successfully from 1918 and manufactured about 5000 tons of pig iron. In 1921 the name was changed to the South African Iron and Steel Corporation, Ltd. From that time until the Iron and Steel Industrial Bill was passed, Mr. Delfos made many visits to Europe endeavouring to raise capital for a large works. It was after his failure to secure capital that the Government stepped in and passed a Bill to form the present corporation.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

COMPRESSED AIR CYLINDERS.

Sir,—I am directed by my Committee to express their thanks for your report on the discussion which took place between members of this Association on "The Testing of Compressed Air Cylinders," on November 15th.

It is regretted that in the notes of the proceedings transcribed for you it was stated that the Admiralty regulations for the testing and examination were "dead." The last word of this paragraph should read "read," as, of course, the Admiralty have gone very thoroughly into this question and they lead the way about the procedure to be adopted.

J. Hope Harrison, Joint Hon. Secretary,
Diesel Engine Users Association.
307, Abbey House, Westminster, London, S.W.1,
November 29th.

THE NEWCOMEN SOCIETY.

From the twelfth annual report, covering the session 1932–33, of the Newcomen Society, we learn that during the year sixteen new members were elected. On October 1st, 1933, the membership of the Society totalled 323.

During the year under review there were eleven meetings, viz., eight in London, one a joint meeting in London with the Omnibus Society; two in New York; and the summer meeting in Cornwall.

As the outcome of a paper by Captain Smith on November 16th, on "Joshua Field's Diary of 1821," Miss Field has agreed to present Part II. of the Field Diary to the Science Library. It is gratifying to be able to record that the Shetland Water Mill, described in Messrs. Dickinson and Straker's paper, has been secured for the nation, and will shortly be exhibited in the Science Museum. Arising out of Mr. Dickinson's paper on "Joliffe and Banks, Contractors," last session, Sir Edward Banks's tomb at Chipstead, Surrey, has been restored by the chairman of the Bridge House Estates Committee of the City of London—Mr. J. J. Edwards—at his own expense. The President, on behalf of the members, on January 18th, presented to E. A. Forward a silver salver in recognition of his valuable services as Hon. Treasurer of the Society, practically since its inception.

With regard to the preservation of objects of outstanding interest, the Society supported the appeal for, and contributed to, the preservation of Sprowston Windmill, Norwich, which, unfortunately, has since been burnt down. The Society is, through local members, keeping a watch over the Iron Bridge, 1779, at Coalbrookdale. During the year under review, Extra Publication No. 3, "The Aeronautical and Miscellaneous Note Book, *circa* 1799–1826, of Sir George Cayley," was published, and the Council is open to consider suggestions for another such publication. Volume XI. of the "Transactions" was issued, and Vol. XII. is in the press.

As the majority of members are unable to attend meetings, and are, therefore, dependent on the "Transactions," the Council has been considering ways of increasing their interest by ensuring that they receive copies of publications sooner. It was decided, therefore, that Rule X. shall be taken to mean that "Every new member, when his first subscription is paid, shall receive a copy of the "Transactions" and any Extra Publications issued during the session in which his election takes place, and that as soon as his resignation is accepted or death reported, no further publications shall be sent, and that such action shall be retrospective." Consequently, ninety members have become entitled to back numbers of "Transactions," and in response to the Hon. Secretary's invitation, seventy volumes have been posted.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

INSULATING VARNISH.

No. 514—1933. This specification deals with baking varnish of the bitumen type, which gives a finished film which is flexible, moisture-resisting and capable of withstanding vibration without chipping or cracking. The varnish covered by the specification is suitable for the impregnation of coils, including those of electric traction plant, and for use in any situation where apparatus is subjected to vibration. The specification is based on the results of considerable investigations made by the British Electrical and Allied Industries Research Association, and is drafted in the usual form of clauses defining the performance limits, followed by appendices describing in detail the methods of testing to be employed.

RUBBER TUBING FOR PETROL, &c.

No. 4 F 7—1933. This is a revised specification for Rubber Tubing for Aircraft Purposes, and its scope is limited to rubber tubing for use with petrol, benzol and paraffin, the previous edition 3 F 7 having included lubricating oils. Two classes of tubing are dealt with, namely, ordinary tubing and embedded wire tubing. The sizes range from $\frac{3}{16}$in. to $1\frac{1}{2}$in. internal diameter. The standard methods for determining the strength of the canvas, the chemical analysis of the rubber compound, the permeability to petrol, the resistance to benzol, and the resistance to accelerated ageing of the finished tubing are fully described.

Railway and Road Matters.

On a recent occasion the up "Queen of Scots" Pullman train on the London and North-Eastern route left Leeds 18 min. late, but arrived punctually at King's Cross. It thus covered its non-stop journey of 186 miles in 175 min. The 156 miles from Doncaster were run in 139 min., or an average speed of 67·3 miles per hour. The load behind the tender was 295 tons and the engine was "No. 3284," an "Ivatt Atlantic," built in 1904.

Public notice has been given by the Southern Railway Company of its intention to apply to Parliament during the present session for certain powers, amongst which is authority to build a railway, 4 miles long, from a junction with the main line near Folkestone to a junction with the same line 557 yards east of Abbotscliff Tunnel. This sounds to us like a deviation railway to avoid the possibilities of the main line being obstructed by falls of cliff, as happened during the war. The London, Midland and Scottish also has given notice of a Bill. As regards new railway works it is very vague, as the notice speaks only of the "construction of railway and works in the urban district of Hazel Grove and Bramhall in the county of Cheshire."

A note in the *Electrical Review* says that the whole State railway line between Malmö and Stockholm, a distance of 599 kiloms., had been electrified by October 1st, and on December 1st electric traffic was starting on the Malmö–Trälleborg line, a distance of 31 kiloms., so that after that date the trains for the Continent will be hauled all the way from Stockholm to the south of Sweden by electric locomotives. Electrification work on other important State railway lines continues, and it is hoped that the Oerebro–Krylbo junction line (132 kiloms.) will be opened for electric traffic on October 1st, 1934. When this electrification is complete, express trains from Malmö and the Continent to Norrland towns will no longer run *viâ* Stockholm, but *viâ* Mjoelby–Hallsberg–Oerebro–Krylbo, thus saving much time.

The Railway Returns do not give the number of privately owned wagons; only of those that belong to railway companies. All the former class, before they are put into service, have, however, to be registered by the Railway Clearing House. The number of these is given in the Railway Returns, and from that source we learn that 902 were registered during 1932, as compared with 1287 in 1931 and 4774 in 1930. Those registered last year included 383 20-ton coal wagons and 453 12-ton coal wagons. The number of containers owned by British railways on December 31st, 1932, was 7027, as against 6290 in 1931; of the former, 2405 were open containers, 4610 were covered, and 12 were "roll-off." The average tonnage capacity was 3·37 tons.

Among the fatal accidents to railway servants during the March, 1933, quarter, mentioned herein on November 24th, was one to a capstanman. That unfortunate man was killed by an explosion in the pit of an electrically operated capstan. There was an accumulation of coal gas in the pit which had come from a defective pipe situated close to an electric distribution box. The gas pipes have now been moved away, and as a further, and more effective, precaution, the holes where the cables enter the cast iron boxes in which the capstans are housed have been sealed. Mr. J. L. M. Moore, the assistant inspecting officer, in reporting on the accident, says that the sealing of all holes below ground level, which lead into the pits of electric capstans, appears to be desirable, and might with advantage be made the subject of a general instruction.

As Mr. Herbert Morrison was one of the most businesslike men to fill the office of Minister of Transport, his remarks on transport command respect. It should be noted then that, speaking at York on Thursday, December 1st, on some problems of the transport industry, he said: "We would bring all railway companies and all long-distance road passenger and goods undertakings under one great national corporation, which should be a public authority running the services as a public concern and for the public advantage. It may be that canals, coastwise shipping, and ultimately air transport should also be brought in. Provision may possibly have to be made for some departmentalisation and some decentralisation, but it is important from the public point of view that transport shall be dealt with as a whole by men who are transport minded, and not by men who have merely railway, road, canal, shipping, or aircraft minds.

The collision of September 8th, at Bowling on the Glasgow–Helensburgh section of the London and North-Eastern Railway, between an express to Glasgow and four empty trucks, mentioned herein on the 15th idem., was inquired into by Lieut.-Colonel Anderson, whose report thereon has recently been issued. It appears that on the morning in question some wagons had to be transferred from sidings on the up side of the line to other sidings on the down side. The wagons were propelled by an engine on to the up main line, and should then have been drawn through a cross-over road on to the down line and propelled thence into the down siding. The shunter, however, first failed to couple all the wagons together, with the result that when the engine went through the cross-over road four wagons were left behind on the main line, and the shunter's second error was his failure to notice this. The signalman now made an error, as when the express was offered to him he did not ascertain that the line was clear, and the collision resulted. There were no serious personal injuries and surprisingly little damage to rolling stock. On the latter feature, Colonel Anderson remarks that although the engine of the express and the six bogie coaches were all derailed, there was no overturning or telescoping, and there was only one broken window in the whole train. Although track circuit would have prevented the collision, Colonel Anderson—to his credit be it said—remarks that there are many other places where equipment of this kind is, owing to worse local conditions, still more desirable; and this accident might equally have been prevented by the exercise of a very little care and obedience to rules on the part of the men principally concerned. "I therefore make no recommendation as to the provision of such apparatus."

Notes and Memoranda.

A section of a noteworthy tree has been sent to the Imperial Forestry Institute at Oxford. It was sent by the Government of Nigeria, and was cut from a mahogany tree having a girth of 60ft. at 3ft. from the ground and 42ft. at 6ft. The main stem was 154ft. high, and yet it is said that there is another even larger mahogany tree close by.

The most favourable time to apply calcium chloride to gravel roads, to preserve their moisture, is, according to Mr. B. C. Tiney, of Michigan, during the drying period just following a rain, after the surface has been bladed to proper smoothness. The moisture in the road at that time hastens dissolving and penetration. In the absence of rain, application in the early hours of the day, when the air has high relative humidity, is very desirable. Application just prior to rain should be avoided, because of the loss from washing off the road.

The Budapest radio broadcasting station, which has been equipped with a new 120-kW transmitter, has what is claimed to be the world's highest aerial mast, the highest structure in Europe and the third highest in the world. It is of steel trellis work, guyed in the middle, and is 932ft. high. To this must be added the telescopic steel pole, which can be pushed out at the top to bring the total height to 1022ft. It was built under the direction of a British firm of contractors which own the patents of the system under which it has been constructed.

Some solid steel piling which was driven in the Gulf of Mexico thirty-one years ago, and has not since been painted, was recently inspected by the Carnegie Steel Company, which rolled the original steel. It was found that the piles were covered with a scale, which, in places, was as much as 2in. thick, but the loss of metal by corrosion was nowhere more than ¼in. The piles were originally 6in. in diameter. In an account given in the *Engineering News-Record*, the composition of the piles is not disclosed, but steel in other parts of the structure is said to have the following composition:—Carbon, 0·25; manganese, 0·43; phosphorus, 0·020; sulphur, 0·029; and copper, a trace.

The possibility of the widespread use of rhodium in electro-plating was discussed at a recent meeting of the Electro-Depositors' Technical Society, when Mr. R. N. Atkinson demonstrated a process which has recently been patented. The new finish, rhodium, possesses remarkable properties. It is extremely hard, and its resistance to the attack of acids is superior to any other plating metal. As an offset to the high cost of the metal, it has been found that a very thin plating—no more than one ten-millionth of an inch—is remarkably continuous, and will resist corrosion and wear to a high degree. The plating process is rapid, taking no more than five to fifteen minutes to complete.

Commenting on the proposal of Dr. Cosyns, who collaborated with Professor Piccard in his ascent into the stratosphere, to make a similar exploration next April, *Nature* explains that the doctor's plans are to investigate, during his ascent, the energy of the total radiation of the sun, in order to determine the calorimetric intensity and the pressure of light of the sun. He will also collect, at various altitudes, samples of air for subsequent analysis. Another practical problem he has to solve is how to enable his balloon to ascend uniformly and slowly, and how to stabilise it eventually at certain heights, his reason being that taking observations during the rapid ascent of the balloon cannot be accurate enough to allow him to draw any final conclusions. Of course, once the balloon has reached the stratosphere it is almost perfectly steady.

A new film camera capable of taking 2000 pictures a second and recording time as well has been developed in the research laboratories of the Western Electric Company. During laboratory experiments recently carried out it was revealed that pieces of cracked glass from a shattered electric light bulb resembled a slowly drifting snow-flake when photographed with this high-speed camera. A flashlight produced the effect of slowly lighting a stage. In the darkened chambers of a small testing booth the wink of an eye seemed to take minutes. A golf ball, at the moment when the club struck it, appeared to be deflated to two-thirds of its original size. It is believed that the camera offers possibilities of measuring deflection and displacement and of catching the flash movements of the ejection of a shell, and the explosive action of gases in a combustion chamber.

Whatever may be the advantages of welded steel construction for other types of machinery, the machine tool designer, says *Machinery*, shows little inclination to depart from the conventional iron casting. In order to meet the more arduous conditions which modern rates of metal removal impose, however, an improvement in the quality of castings is frequently essential, and in many cases is obtained by the use of nickel cast irons, of high strength, good wearing qualities, and fine finish. For the general run of machine tool bed and frame castings, a semi-steel mixture containing nickel and chromium gives excellent results. This material, moreover, eliminates the need for chilling, so that not only is the casting operation simplified but the severe internal strains set up are largely avoided. In addition, the uniform structure of nickel irons renders ageing unnecessary, an important advantage in many cases.

There has recently been erected for the Spalding U.D.C. a 0·1 square inch flexible segmental conductor which is circular and not stranded. The work has been carried out under the supervision of Mr. F. R. C. Roberts, the Council's engineer and manager. The inventor of the conductor, Mr. A. Avis, is managing director of the Segmented Wire Corporation, which was responsible for the work. It is claimed that the use of this conductor effects a reduction of 25 per cent. in the cost of an overhead line, apart from its easing of wayleave difficulties due to the possibility of using longer spans. The same type of conductor is also being supplied to Spalding in underground cable, made by the Metropolitan Cable and Construction Company, Ltd., under licence from the Segmented Wire Corporation. We believe this is the first occasion on which this type of conductor has been so employed.

Miscellanea.

A new seam of coal has been discovered at the Denton Colliery, Cumberland.

The Brymbo Steel Works, Wrexham, are to be reopened. There should be employment there for 1500 hands.

The old paddle steamer "Caledonia," which has plied on the Clyde for over forty years, has been laid up and will probably be broken up.

Twenty-two European countries will grant special travelling facilities, representing savings of from 10 to 33 per cent., to visitors to the British Industries Fair next February.

First-class crystal graphite has, it is said, been discovered recently by a geological expedition, on the northern slopes of the Turkmenistan Mountains, near the source of the Kshernysh River.

There is some talk in America of cutting a ship canal across the upper end of the Florida peninsula. It would be 166 miles long, have a bottom width of 200ft., and a depth of 38ft. The cost is estimated at 138,000,000 dollars.

It is reported from Athens that coal has been discovered in Greece. The seam is in the district of Tamonaia, near the marble quarries of Karystos, in the south of the Island of Eubœa. The analysis is said to have shown satisfactory results.

A factory for the manufacture of ammonia sulphate is to be put up in Japan by the Mitsui Company. It is to have an output of 120,000 tons a year, will cost about £2,000,000, and will be adjacent to the atmospheric nitrogen plant at Miike.

Non-metallic minerals—other than fuels—are now produced in America to the value of approximately a thousand million dollars a year, or nearly that of all the metals combined, while this annual value is increasing at a faster rate than that for the metals.

The inhabitants of the Paotsing district of Manchukuo have petitioned the Manchukuo authorities to construct a railway from Lishuchen to Paotsing, 130 miles. They point out that the district is very fertile and that the scheme, if carried into effect, will prove profitable.

A scale model of a Loeffler high-pressure boiler is now being exhibited in operation in the Science Museum, South Kensington. The model represents the type in use in the Trebovice power station, designed for a pressure of 1900 lb. per square inch and a superheat temperature of 950 deg. Fah.

Until comparatively recent years, the sea passage to the Kara Sea was considered to be an impracticable route for navigation, but it has now been shown that this is far from being the case, and there is every indication that it is likely to assume increasing importance in connection with the import and export trade of the U.S.S.R.

The Coal Mines Reorganisation Commission has been informed by the West Yorkshire coalowners that the scheme of partial amalgamation which has been under consideration in that district for some time has broken down. It gained the support of coalowners responsible for nearly 70 per cent. of the output of the district, but the rest have refused to join.

For the purpose of transporting sixteen railway coaches, built by the Birmingham Carriage and Wagon Company, to Liverpool for shipment to Brazil, *viâ* the G.W. and L.M.S. railways, it was necessary temporarily to remove thirty signal posts, as the coaches were too wide for the English loading gauge. The journey of 90 miles occupied nineteen hours, and required a train gang of twenty men.

Coal has been discovered near the source of the Bolshaya Karachevka River, 75 kiloms. from Magnitogorsk, by the Ural Geological Investigation Committee. A shaft sunk in the Mikhailovsk settlement has revealed at a depth of 9 m. three layers of coal of a satisfactory quality from 1½ m. to 3 m. thick. According to the preliminary investigations, the coal deposits extend over a considerable area.

A Micro-chemical Club is being formed by a number of scientific workers interested in the use and improvement of micro-chemical methods, for the purpose of developing interest in the science, pooling ideas, and subscribing to certain journals. The secretary of the Club, Dr. M. Healey, Wellcome Physiological Research Laboratory, Beckenham, Kent, will be pleased to answer inquiries from anyone who is interested.

Work has just been started on the Bonneville dam on the Lower Columbia River at Grande Coulee, Washington, which is at the head of tidewater. The head available for power purposes will be 62ft., and 90,000 kW is to be developed by the first two units. There is sufficient water for from ten to twelve units. The reservoir will be about a mile wide by 50 miles long, and will be used for navigation. The cost of the works is estimated at 31,000,000 dollars.

Many engineers will hear with regret of the death of Mr. J. W. Harris, of Gloucester, on November 23rd. Mr. Harris started his engineering career with Fielding and Platt, Ltd., and in 1902 joined the staff of what was then the Universal Tube Company, Ltd., Derby-road, Chesterfield, which undertaking was later acquired for the Chesterfield Tube Company, Ltd. Except for six months spent in America, Mr. Harris remained at Chesterfield as chief engineer until 1928, when he was compelled to live in the South of England for health reasons.

In 1927, eight Babcock and Wilcox boilers were installed in the Kearsley power station of the Lancashire Electric Power Company, each for an evaporation of 75,000 lb. of steam per hour at 305 lb. per square inch, and 700 deg. Fah. final temperature. This station was fully described in our issues of July 31st and August 7th, 1931. It has recently become necessary to increase the evaporation of each unit to a normal load of 95,000 lb. of steam per hour, and in July last Babcock and Wilcox, Ltd., received an order for a Bailey water-cooled furnace to permit this increase of load. This Bailey furnace has now been in operation for some weeks, and a decision has already been reached to equip similarly the remaining seven boilers.

MULTIPLE MARINE OIL ENGINES.

In the sixth Thomas Lowe Gray Lecture, which is summarised in our present issue, Mr. H. R. Ricardo presents an able case for the use of really high-speed oil engines in combination with electric generators for ship propulsion. As the President of the Institution of Mechanical Engineers pointed out when introducing the lecturer on Friday evening last, probably no engineer has done more than Mr. Ricardo to further the development of the high-speed oil engine. His proposals, therefore, deserve the careful consideration of the marine engineer and naval architect, even although, at first sight, they do appear to be somewhat revolutionary in character. The idea of utilising multiple engines for an electrically propelled liner is not entirely new, for a few years ago a scheme was, to our own knowledge, planned and put forward by a leading British shipbuilding firm for a very large Atlantic liner in which a great many engines driving generators formed the propelling and auxiliary machinery. These units, were, however, fairly large power engines running at a medium speed, whereas Mr. Ricardo advocates smaller and lighter high-speed units. Although he limits the proposed use of oil engines to ships of not more than 6000 B.H.P., we cannot agree with his suggestion that a case cannot without difficulty be made out for the use of oil engines in really large and fast vessels. In this connection it is worthy of mention that two of our most successful Atlantic liners are motor ships of close upon 27,000 gross tons, and are propelled by 8500 B.H.P. engines, and that several motor vessels recently ordered for Australia, New Zealand, and other services, have machinery considerably more powerful than the limit of 6000 S.H.P. Mr. Ricardo postulates. This self-imposed limitation does not affect in any way the proposals he puts forward, which, however, if they are to be attractive, must be framed to appeal to the shipowner on the essential grounds of first cost, weight and space, and operating and maintenance costs.

Remembering, perhaps, R. L. Stevenson's advice to essayists, Mr. Ricardo missed no opportunity of vivifying his lecture and in consequence, some of his figures and points are meant to be more effective than precise. For example, his figure of no more than 4000 hours at sea per annum is scarcely typical of modern motor ship practice, for which yearly duties of 200, 250, and, in special cases, up to 300 days at sea are on record. Again, Mr. Ricardo is not quite correct in his assumption that the marine oil engine develops no more than two-thirds of its maximum power at sea. There are many instances in which the machinery is called upon to operate, and does operate successfully, at outputs close upon, and even higher than, the trial trip performance. It must, however, be conceded to Mr. Ricardo that the marine oil engine has, as he claims, if anything a lighter duty to perform than an engine operating under road or rail transport conditions. As to his estimate of the cost of engines, we fear the possibility of manufacturing high-speed oil engines at £2 10s. or £2 per horse-power is at the present somewhat remote. Colonel Fell, in a paper on compression-ignition engines for railway service, read before the Institution of Mechanical Engineers about a year ago, gave a figure of £2 10s. for the oil engine unit, and, incidentally, £8 for the electric-traction equipment. That oil engine figure was much criticised at the time, and the present price of an engine is nearer £4 to £5 per horse-power, to which must be added, say, at least a further £5 per horse-power for electrical equipment, including propelling motor and switchgear. This gives £9 to £10 total, which compares with about £6 per horse-power for slow-speed oil engines of modern design. Indeed, when the high cost of the electrical equipment is taken into account, we fear it will be difficult to present an attractive case for Mr. Ricardo's scheme on engine cost. On the other hand, there are undoubtedly considerable advantages in his proposal in the equally important matters of weight and space. Although he gives a weight of about 1½ tons for each of the seventy-five generating and auxiliary units, making a total of over 112 tons, he presents no particulars of either switchgear, the propelling motor, or the auxiliary pump weights, all of which will add considerably to the weight of the total installation and probably make it heavier than a direct driven machinery arrangement. With regard to space, however, it may be noted that with a beam of 60ft., an engine-room length of only 27ft. 6in. is required by Mr. Ricardo, which compares with an engine-room length of about 60ft. for engines of normal design. It is also probable that there will be some saving in the space required for auxiliaries and uptakes. Further savings, we may suggest, might be made if high-speed multiple propellers were to be employed instead of a single large motor and its propeller. With regard to operating and maintenance costs, some interesting figures are put forward by the lecturer, but again they must be set against results which are being obtained in modern motor vessels. In a Doxford-engined ship which was quite recently completed, the total fuel consumption for the main engine—which drives most of its auxiliaries—is only 0·36 lb. per B.H.P.-hour, a figure which the high-speed oil engine will find it difficult to rival or surpass. It would also seem true that the consumption of lubricating oil for the few cylinders of a large, slow-speed engine would be considerably less than for the hundreds of cylinders of the small high-speed oil engines, for which Mr. Ricardo assumes, we note, a flow of about 200 gallons per minute. These are factors which need to be considered in fuller detail. The repair costs mentioned by Mr. Ricardo are very high when it is remembered that liners and main running parts in a modern oil engine will run for four years at full power, and a further two years when de-rated without needing serious repairs which may be generally taken not to exceed per annum 1 or 2 per cent. of the engine cost. The higher cost of high-speed engine repairs may be partly explained by the reason that when running at 1600 to 2000 r.p.m., the fatigue limit of piston rings, valve springs, anti-friction metal bearings and other wearing parts is reached earlier than would be the case with a slow-speed engine running at 90 to 100 r.p.m. But "the proof of the pudding is in the eating," and we venture to suggest that Mr. Ricardo, in collaboration with an electrical engineer and a naval architect, should work out more fully his interesting proposals for three different ships—a fast Thames passenger vessel, a large cross-Channel motor ship, and a cruising liner, of, say, 10,000 tons. A paper based on that examination might well be presented and discussed at the spring meeting of the Institution of Naval Architects. The locked engine cell is familiar in the naval pinnace and motor cruiser, but it could quite well and properly be extended to meet the needs of a fast-running fleet of passenger vessels plying on the Thames. We commend this suggestion to the London Passenger Transport Board, which, in collaboration with the Associated Equipment Company, Ltd., has built up such a valuable amount of experience in the operation of high-speed oil engines in road service. That experience could at once be applied to river traffic if suitable designs were forthcoming. For the cross-Channel vessel we venture to suggest that the Southern Railway Company, which has done such pioneer work in electric railway traction, might be persuaded to look with favour on the design of a large, electrically propelled motor ship for cross-Channel service which could be fully stabilised and should then prove a very popular ship. It is well known, too, that, despite the recognised success of summer and winter cruises we have in our British mercantile fleet no single class liner specially designed for this work. Such a machinery arrangement as described by Mr. Ricardo might be worked out with advantage for this special class of ship. If one or more of these vessels were to be built, then the dream of Mr. Ricardo—we believe it to be a dream and not a nightmare, as he himself half fears—would become a prophecy, and what he ardently desires—the furthering of British enterprise and marine engineering prestige—would be achieved.

We offer these criticisms not in a spirit of conservative opposition, but because the lecture was provocative as Mr. Ricardo meant it to be. New ideas, emanating from men of well-established reputation, are to be welcomed in every branch of engineering. It is so fatally easy to get into ruts which, as the years pass, grow deeper and deeper, till we are unable to peer over their edges. Every now and then some more daring than the rest stand on tiptoe and get a peep of a wider horizon. Opposition to their proposals there is bound to be, because the conditions which favour existing designs have, to a great extent, grown up with those designs, and it is, therefore, always easy to prove that what is is best. But every engineer should welcome excursions of a lively fancy, especially when they are made by men who have established their right to speak and present their case with technical knowledge. Mr. Ricardo's lecture will be a source of debate for months to come, and we may yet see his vision realised. More wonderful things have happened.

Parity in the Air.

Ten years ago Mr. Baldwin made an official declaration of his Government's policy concerning the aerial strength of this country. After meeting the essential air requirements of the Navy, the Army, India, and other overseas commitments, Great Britain, it was laid down, should possess an Air Force strong enough to protect her against attack from any air force within striking distance of her shores. Succeeding Governments have not openly discarded that policy, but from its initiation it has never been more than a guiding principle. Deliberately and without secrecy this country's air strength has been cut down, and kept down. It was fondly hoped that the standard envisaged in 1923 would be reached, not by Great Britain increasing her aerial strength, but by other nations following her example and reducing theirs. Willingly this country would have gone so far as the complete abolition of all naval and military aviation—subject only to a satisfactory system of international control being devised effectively to prevent the misuse of civil machines for war purposes. These aspirations and efforts towards total or partial aerial disarmament received little or no support abroad. As a consequence, this country now finds itself fifth—or possibly sixth—in the order of the world's air powers as judged by the number of machines possessed. We are to-day, it is asserted, at least ten squadrons—or, say, a hundred effective machines—short of the minimum deemed necessary for home defence. To cover the whole of our requirements at home and abroad we have approximately 850 first-line machines. Of these machines, it is understood that about 490 are stationed in Great Britain, the rest being in India, Egypt, Palestine, and elsewhere overseas. The French Air Force has about 1650 first-line machines. The Soviet Republic owns, it is believed, between 1300 and 1500. Italy and the United States possess something over 1000 each. The aerial strength of Japan is not known with any assurance, but is undoubtedly of a high order. Facing the realities of the position, the Government has now determined that our present relative weakness in the air cannot be allowed to continue. On Wednesday of last week, simultaneous statements on the subject were made in the House of Lords and the

House of Commons by Lord Londonderry, the Secretary for Air, and by Mr. Baldwin. By one means or another the Government is now determined to secure parity in the air with any other single Power. If other nations will not come down to our level we are to build up to theirs.

That this country is in a position to make itself as strong in the air as the strongest there cannot be a shadow of doubt. The British aeronautical industry, thanks largely to the enlightened policy of the Air Ministry, is, in all its aspects, highly organised, strongly established, and efficient. It is capable of supplying and does supply the Royal Air Force with all the machines, engines, instruments, and military equipment which it requires, and in addition contributes in no small measure to the material requirements of certain other nations' air forces. Its organisation and its present position are certainly such that it could quickly respond to a greatly increased demand for machines. As regards its capacity to develop on the technical side and to remain in the van of progress, we have the knowledge that behind it there is a large and able body of investigators, Government and private, liberally equipped to carry out their important duties and in full and harmonious contact with the manufacturing side. Incidentally, the revolution effected since the end of the war, by which the use of wood for major purposes has been abandoned in favour of steel and light alloys, has freed the industry from dependence in any way upon imported supplies of materials. We can, then, rest assured that the building up of Britain's air strength to parity with that of any other nation—and doubtlessly to something more than parity if it were desired—is well within the compass of what the British aeronautical industry is to-day capable of achieving. However parity may be defined, whether it be regarded simply as synonymous with numerical equality or be judged on a more comprehensive basis, this country has the power to realise it. It must not, however, be overlooked that the Government's policy is not intended in any way to be aggressive, and that aerial disarmament, partial or complete, is still earnestly desired. A foolish and wasteful era of competition among the nations of the world for aerial supremacy is the last thing which the Government or anyone else desires to see. Efforts to secure aerial disarmament will be continued, but they will now be made in a new, and, it is to be hoped, a more salutary atmosphere. Unarmed among armed nations, this country, as Lord Londonderry said, cannot speak with authority. British weakness in the air, conditions being as they are, is a menace to peace. "The armed strength of Great Britain has invariably been thrown into the scales upon the side of peace, and there could be no greater encouragement to the aggressive policy of any nation than the knowledge that the sword of Britain is no longer heavy enough to tip the scale against aggression." In these words the Secretary for Air sums up the true implications of this country's new air policy. That that policy may be misunderstood or misinterpreted abroad is distinctly possible. That patience and diplomacy and more than a little skill will be required to guide it to the desired end and not to one diametrically opposite to that intended is certain. The difficulties of the situation are patent, but it cannot be doubted that they are less than those in which the continuation of the one-sided disarmament policy of the past ten years would at no distant date have involved us. The old method having failed, the same object is to be sought from the opposite direction. The reversal of the mode of attack inevitably involves risk, but it substitutes for a negative policy based on hope an active one founded on realities.

In discussing this subject one cannot fail to perceive that it has many issues and many points of contact with other aspects of international affairs. What, for instance, is applicable to the air is, with certain changes, applicable to the Navy and the Army and their equipment. It is doubtlessly because of this fact that Mr. Baldwin, in the course of his remarks last week, introduced a short but important passage in which he indicated that it was the Government's intention to consider the three Services together and to repair their deficiencies as a whole. Again it would be folly to ignore the bearing which our new policy in the air must have on the problems presented by Germany's demand for equality in armaments. If we are persuaded that parity for us is essential for the preservation of peace, can we resist a similar argument advanced on Germany's behalf? Confining ourselves, however, to the strictly aeronautical aspects of the subject, we find in the new policy and the situation which has forced it upon us two outstanding factors which demand careful consideration. First, it is clear that the new policy leaves the problem of the international control of civil aviation as acute as, if not more acute than, before. Parity with respect to military and naval aeronautical equipment will be an illusion and a dangerous deceit if the nations are to be allowed unrestricted freedom to build and operate civil machines capable of being converted at short notice for war purposes. Secondly, if our determination to secure parity is, as intended, to be an influence working towards peace and not a factor promoting international discord, it will be necessary to make it clear from the outset what is meant by parity, whether merely the number of machines possessed is to be taken into account or whether in its assessment allowance is to be made for their quality and equipment, their geographical distribution, and the facilities possessed for their replacement and multiplication in a time of emergency. Each country may reasonably claim to be the best judge of what constitutes parity in its own case. If, however, the principle of parity is to prove a source of international harmony and not of continued disagreement, if it is to create a sense of security and not distrust, an internationally agreed meaning must be sought.

The Road Accidents Report.

A MONTH ago, in a leading article entitled "Road Accidents," we stressed the desirability, before any legislative action was taken, of collecting together all the available data with regard to such accidents. By the analysis of these data we contended that the underlying causes of accidents might be discovered and that legislators would then be in possession of facts rather than opinions on which to base any action that seemed desirable. We mentioned that we believed some such collection of statistics was being made. The issue by the Ministry of Transport of a Preliminary Report on Fatal Road Accidents, which is concerned with the period of six months ending on June 30th last, indicates that the matter is being taken seriously in hand. This report will, presumably, be followed by others analysing the figures to a greater extent, and taking into account also the non-fatal accidents. Although valuable in the sense that they give a general impression of the complexity of the field to be covered, the tables included in the report in their present form give but little information upon which any action might be taken. Certain misconceptions can be held to be definitely disproved, however. For instance, only 133 drivers out of 4041 involved in fatal accidents had had previous convictions for dangerous or careless driving, so that the "road hog" cannot be held mainly responsible for accidents. In fact, the impression conveyed by the report is that the majority of drivers involved in fatal accidents are quite undistinguished in any respect from their more fortunate fellows. More than half of the deaths occurred among pedestrians; and cyclists, both motor and pedal, together accounted for more than another third. While such figures have a melancholy interest for everyone, whatever his profession, trade, or vocation, they are useless to the engineer who hopes by his own efforts to do something to bring about a reduction in the toll of the road. The mechanical engineer, it is true, can gain some satisfaction from the very small proportion of vehicles in which mechanical failure of any part was either the main or a contributory cause of the accident. But as as far the road engineer is concerned, the report is disappointing. He will find little guidance in it, but may derive satisfaction from the fact that in only 237 cases out of 4253 was any defect in the road held responsible as the main or contributory cause of the accident. Amongst drivers, however, this figure has already been criticised as suspiciously small, as the general expectation was that the state or configuration of the road would be found as a contributory cause in a by no means negligible number of accidents.

Literature.

The Unemployed Man: A Social Study. By E Wight Bakke, Ph.D. London: Nisbet and Co., Ltd. 1933. Price 10s. 6d.

The author of this book on unemployment in England is the Director of Unemployment Studies in the Institute of Human Relations in Yale University. With the help of a Sterling Fellowship from his University he came to this country in 1931 to gather information for a thesis on this question: "What has been the effect of unemployment insurance on the willingness and ability of workers to support themselves?" He began with the intention of pursuing his research in the ordinary economic way through blue books and white papers. He meant to analyse studies which had been made and statistics which had been gathered. But he found that "there were no studies and no statistics." So he betook himself to the Ministry of Labour to seek help in the formulation of Sample Inquiries; from which it will be seen that he proposed to do just what any other economics research worker might have done. Fortunately, he was deflected from that dull course. Mr. John Hilton, at the Ministry, put a new idea into his head: "to take lodgings with a working-class family, to share their life in so far as it was possible to do so, to join in their activities or loaf on the streets or at factory gates as the occasion might require, to go with them to clubs and churches and 'pubs,' to join the hunt for a job, and during the whole process find out all I could of the causes and consequences and adjustments involved in unemployment among the men and women who were unemployed."

It was a good idea, and Dr. Bakke carried it through well. It must have been difficult at times to get into touch, into sympathy, with the loafers whom he joined at street corners and public houses. But he managed it, and in consequence we have a book which looks at one of the greatest problems of the day, not from the standpoint of the detached scientific worker, but intimately from the inside. The author shows us how his out-of-work companions spent their time, and he increases our respect for them at the same time that he makes us admire the tact and persistency with which he stuck to a delicate task.

His field of operations was Greenwich. He may regret now that he did not go into the heart of one of the great industrial cities—to Glasgow, Manchester, Sheffield, and Birmingham. It is probable that he would have found there a different type of unemployed man from that which hangs upon the fringes of the Metropolis. But, having decided to work within the County of London, he could not have done better than settle at Greenwich, a long narrow borough "self-contained to an unusual degree and little influenced by special factors of population, social conditions, or employment." His experiences opened in a working-men's club, and were carried on in all sorts of surroundings. He appears to have got into real intimacy with men and women, both employed and unemployed, and is able to show us a good deal of their real reactions to the influences around them. The suspicion must inevitably arise that his "subjects," knowing what he was about, played up to him. We do not think that, in fact, they did so. The simple background of their thoughts which he reflects has struck many observers, and can be confirmed by all who, like engineers, have worked for years shoulder to shoulder with British workmen. Of course, there are exceptions—some of them, we suspect on the surface rather than deep-seated—but Dr. Bakke's observation that "the normal tendency of workers to look towards a readjustment of income within their class as a remedy for their unfavourable position, rather than towards a redistribution of wealth in which that now going to another class would come to them," may be taken as truly representative of the attitude of workers as a whole, at any rate in southern counties.

One of the forces that plays continually upon the working-class man "is the impression that his destinies are controlled by beings outside his ken." This feeling of control has important consequences. "It causes the worker," says Dr. Bakke, "to feel a minimum of responsibility for his own fate; for responsibility goes with control. No one who has not shared the life of the worker can realise the number of points at which the ultimate decision as to his way of life rests with others. Habit breeds attitudes. When so much of your life is ordered by others, why pretend to be able to do anything yourself with the rest?" It sounds deplorable; rather degrading—as if our workpeople were losing all their individuality. But an unbalanced view of it must be avoided. Where many men have to work together for a common purpose, a measure of mass control is inevitable, and, furthermore, it may be safely said that the control under the present system is pure liberty compared to the control which would be exercised in a Utopian State. Let us quote again: "The fact that certain people habitually control has, in the minds of numerous workmen, created the feeling that special qualifications are required for that function. This feeling may even extend to distrust of his own class on the part of the worker. . . .

Dogmatic and relentless class loyalty among the workers with whom I lived is a myth. The most intelligent denunciation, the most ironic criticisms of labour leaders, industrial and political, came not from professional and business men, nor yet from Communists, but from comfortably situated skilled and semi-skilled workmen. At times this faith in the adequacy of the 'masters' approached very close to reverence for their powers." And why not? If soldiers in the field, or sailors on their ships, may reverence the ability of the Napoleons or Nelsons who lead them, why not the workers in some great industry? In the old days, before great amalgamations had weakened the personal touch, and to this day in many a factory, the devotion to the employer and the pride in his achievements and the achievements of his works, was, and still is, one of the most important factors in the maintenance of our industries in peace and prosperity. "I could find," writes our author, "no sign of the hatred of one class for the other, the inevitable gulf between the classes, which is often asserted to exist in England as in other countries. . . . The soil among the British workers is not prepared for the sowing of Communist seed." Whilst our experience prepared us for that conclusion, it is, nevertheless, reassuring to have it from an investigator who has studied the mind of the British workmen with the care shown by Dr. Bakke.

We might turn over every page of this volume and find some comment to make on each, or some shrewd observation to quote, but we hope we have said enough to make all those who take a genuine interest in the great economic problem of the day desire to read it. We shall, however, be expected to say something of the conclusions to which Dr. Bakke's "research" brought him. These he summarises, categorically, in his final chapter, and following him we may present them very briefly under his own headings.
